The Hodge Project

Contents

1 Introduction **20**
- 1.1 What this project is . . . 20
- 1.2 How the project is organised . . . 20
- 1.3 How to read this book . . . 21
  - 1.3.1 The direct route . . . 21
  - 1.3.2 The main line . . . 22
- 1.4 A map of the integrals . . . 23
- 1.5 Sources and status . . . 24
- 1.6 Conventions of the text . . . 24
- 1.7 Mathematical conventions . . . 25

I Foundations **27**

2 Mathematical Logic **28**
- 2.1 Introduction . . . 28
- 2.2 Propositional logic . . . 28
- 2.3 First-order languages . . . 30
- 2.4 Structures and satisfaction . . . 32
- 2.5 Formal deductions . . . 33
- 2.6 The completeness theorem . . . 37
- 2.7 Compactness and the Löwenheim–Skolem theorem . . . 38
- 2.8 The incompleteness theorems . . . 39
- 2.9 Exercises . . . 42

3 Set Theory **44**
- 3.1 Introduction . . . 44
- 3.2 The axioms . . . 44
- 3.3 Relations and functions . . . 45
- 3.4 The natural numbers . . . 47
- 3.5 Ordinals . . . 48
- 3.6 Cardinality . . . 50
- 3.7 The axiom of choice . . . 52
- 3.8 Universes . . . 55
- 3.9 Exercises . . . 56

4 Number Systems **57**
- 4.1 Introduction . . . 57
- 4.2 Arithmetic of the natural numbers . . . 57
- 4.3 Commutative rings and fields . . . 58

4.4 The integers . . . 59
4.5 Divisibility and prime numbers . . . 60
4.6 The rational numbers . . . 61
4.7 Complete ordered fields . . . 62
4.8 The real numbers . . . 63
4.9 Irrational numbers and decimal expansions . . . 64
4.10 The complex numbers . . . 68
4.11 Exercises . . . 69

5 Model Theory **71**
5.1 Introduction . . . 71
5.2 Elementary substructures . . . 72
5.3 Ultraproducts and compactness . . . 73
5.4 Upward Löwenheim–Skolem and categoricity . . . 74
5.5 Ehrenfeucht–Fraïssé theory . . . 76
5.6 Lindström's theorem . . . 78
5.7 Exercises . . . 80

6 Categories **81**
6.1 Introduction . . . 81
6.2 Categories . . . 81
6.3 Isomorphisms, monomorphisms and epimorphisms . . . 83
6.4 Functors . . . 84
6.5 Natural transformations . . . 85
6.6 The Yoneda lemma . . . 87
6.7 Equivalences of categories . . . 88
6.8 Limits . . . 89
6.9 Colimits . . . 90
6.10 Adjoint functors . . . 91
6.11 Filtered colimits . . . 92
6.12 Additive categories . . . 94
6.13 Exercises . . . 94

II Algebra **96**

7 Groups **97**
7.1 Introduction . . . 97
7.2 Groups and homomorphisms . . . 97
7.3 Cosets and Lagrange's theorem . . . 99
7.4 Normal subgroups and quotients . . . 100
7.5 Products . . . 101
7.6 Group actions . . . 102
7.7 The Sylow theorems . . . 103
7.8 Symmetric and alternating groups . . . 103
7.9 Solvable and nilpotent groups . . . 105
7.10 Free groups and presentations . . . 106
7.11 Abelian groups . . . 107
7.12 Exercises . . . 109

8 Rings and Modules **110**
8.1 Introduction . . . 110
8.2 Rings . . . 110
8.3 Ideals and quotient rings . . . 111
8.4 Prime and maximal ideals . . . 111
8.5 Factorisation in integral domains . . . 112
8.6 Polynomial rings . . . 113
8.7 Modules . . . 117
8.8 Vector spaces and rank . . . 118
8.9 Tensor products . . . 119
8.10 Algebras and graded rings . . . 120
8.11 Modules over a principal ideal domain . . . 121
8.12 Exercises . . . 122

9 Fields and Galois Theory **123**
9.1 Introduction . . . 123
9.2 Field extensions . . . 123
9.3 Splitting fields and algebraic closures . . . 124
9.4 Separability . . . 125
9.5 Galois extensions . . . 126
9.6 Finite fields . . . 127
9.7 The fundamental theorem of algebra . . . 128
9.8 Cyclotomic fields . . . 129
9.9 Solvability by radicals . . . 129
9.10 Transcendence bases . . . 131
9.11 Exercises . . . 132

10 Elementary Number Theory **133**
10.1 Introduction . . . 133
10.2 Congruences . . . 134
10.3 Orders and primitive roots . . . 137
10.4 Quadratic residues and quadratic reciprocity . . . 140
10.5 Sums of squares . . . 143
10.6 Arithmetic functions and Möbius inversion . . . 145
10.7 Gaussian and Eisenstein integers . . . 147
10.7.1 Eisenstein integers . . . 149
10.7.2 Failure of unique factorisation . . . 150
10.8 Binary quadratic forms . . . 151
10.8.1 Euler's polynomial and the Heegner numbers . . . 153
10.9 Exercises . . . 154

11 Linear Algebra **159**
11.1 Introduction . . . 159
11.2 Linear maps and dimension . . . 159
11.3 Matrices . . . 162
11.4 Duality . . . 163
11.5 Determinants . . . 164
11.6 Linear systems, Gaussian elimination and the rank . . . 165
11.6.1 Rank and minors . . . 168
11.7 Eigenvalues . . . 170
11.8 Canonical forms . . . 172

11.9 Bilinear forms . . . 175
11.10 Inner product spaces and the spectral theorem . . . 176
11.11 Complex structures . . . 178
11.12 Exercises . . . 180

12 Multilinear Algebra **185**
12.1 Introduction . . . 185
12.2 Tensor products of vector spaces . . . 185
12.3 The tensor, symmetric and exterior algebras . . . 186
12.4 Tensors of type (r, s) . . . 187
12.5 Alternating forms . . . 193
12.6 Orientations and the Hodge star . . . 196
12.7 Forms of type (p, q) . . . 198
12.8 Exercises . . . 198

13 Representations of Groups and Lie Algebras **200**
13.1 Introduction . . . 200
13.2 Representations of groups . . . 200
13.2.1 Unitary representations . . . 201
13.3 Characters of finite groups . . . 204
13.3.1 Computing character tables . . . 206
13.4 Lie algebras . . . 208
13.5 Nilpotent and solvable Lie algebras . . . 209
13.6 Representations of $\mathfrak{sl}_2$ . . . 212
13.7 Semisimple Lie algebras . . . 214
13.8 Weyl's theorem . . . 220
13.9 The root space decomposition . . . 222
13.10 Root systems and the classification . . . 226
13.11 Weights and highest weights . . . 230
13.12 Exercises . . . 232

14 Commutative Algebra **236**
14.1 Introduction . . . 236
14.2 Prime ideals and radicals . . . 236
14.3 Localisation . . . 237
14.4 Nakayama's lemma . . . 238
14.5 Noetherian and Artinian rings . . . 238
14.6 Integral extensions . . . 239
14.7 The Nullstellensatz . . . 240
14.8 Primary decomposition . . . 241
14.9 Dimension theory . . . 242
14.10 Completions . . . 243
14.11 Regular local rings and Dedekind domains . . . 244
14.12 Kähler differentials . . . 245
14.13 Exercises . . . 245

15 Homological Algebra **247**
15.1 Introduction . . . 247
15.2 Abelian categories . . . 247
15.3 Complexes . . . 248
15.4 The long exact sequence . . . 248

15.5 Projective and injective objects . . . 250
15.6 Derived functors . . . 251
15.7 Double complexes . . . 252
15.8 Ext and Tor . . . 253
15.9 Künneth and universal coefficient theorems . . . 254
15.10 Exercises . . . 256

16 Spectral Sequences **257**
16.1 Introduction . . . 257
16.2 Spectral sequences . . . 257
16.3 The spectral sequence of a filtered complex . . . 259
16.4 Double complexes . . . 260
16.5 Exact couples . . . 260
16.6 The Grothendieck spectral sequence . . . 260
16.7 Exercises . . . 261

17 Derived Categories **262**
17.1 Introduction . . . 262
17.2 The homotopy category . . . 262
17.3 The derived category . . . 263
17.4 Injective resolutions of complexes . . . 264
17.5 t-structures . . . 266
17.6 Filtered complexes and strictness . . . 267
17.7 Exercises . . . 267

III Topology **269**

18 General Topology **270**
18.1 Introduction . . . 270
18.2 Topological spaces and continuous maps . . . 270
18.3 Metric spaces . . . 275
18.4 Subspaces, products and quotients . . . 277
18.5 Connectedness . . . 279
18.6 Compactness . . . 281
18.7 Complete and compact metric spaces . . . 283
18.8 Separation axioms, Urysohn and Tietze . . . 285
18.8.1 The hierarchy of separation axioms . . . 287
18.8.2 Separability . . . 289
18.9 Local compactness and proper maps . . . 290
18.10 Paracompactness and partitions of unity . . . 291
18.11 Function spaces . . . 293
18.12 Nets and filters . . . 298
18.13 The Stone–Čech compactification . . . 301
18.14 The Cantor set and space-filling curves . . . 303
18.15 Exercises . . . 305

19 Homotopy and Covering Spaces **308**
19.1 Introduction . . . 308
19.2 Homotopy . . . 308
19.3 The fundamental group . . . 310
19.4 Covering spaces and the circle . . . 311
19.5 The Seifert–van Kampen theorem . . . 313
19.6 Classification of covering spaces . . . 315
19.7 CW complexes . . . 318
19.8 Higher homotopy groups and fibrations . . . 319
19.9 Exercises . . . 321

20 Topological Manifolds and Group Actions **323**
20.1 Introduction . . . 323
20.2 Topological groups . . . 323
20.3 Group actions and orbit spaces . . . 324
20.4 Covering space actions and quotients . . . 326
20.5 Topological manifolds . . . 327
20.6 Constructions of manifolds . . . 330
20.7 Hopf fibrations . . . 331
20.8 Gluing . . . 333
20.9 Exercises . . . 334

21 Singular Homology **336**
21.1 Introduction . . . 336
21.2 Singular chains . . . 336
21.3 Homotopy invariance . . . 338
21.4 Relative homology and exact sequences . . . 339
21.5 Excision and Mayer–Vietoris . . . 339
21.6 Spheres, good pairs and degree . . . 341
21.7 Cellular homology . . . 343
21.8 Homology with coefficients . . . 344
21.9 The Hurewicz theorems . . . 345
21.10 Exercises . . . 346

22 Singular Cohomology **348**
22.1 Introduction . . . 348
22.2 Cochains and cohomology . . . 348
22.3 The cup product . . . 350
22.4 The Künneth formula . . . 351
22.5 Cohomology rings of projective spaces . . . 351
22.6 Cup length and coverings by contractible sets . . . 352
22.7 The cap product . . . 353
22.8 Exercises . . . 353

23 Topological Manifolds and Poincaré Duality **355**
23.1 Introduction . . . 355
23.2 Topological manifolds . . . 355
23.3 Orientations . . . 356
23.4 The fundamental class . . . 356
23.5 Cohomology with compact supports . . . 358
23.6 Poincaré duality . . . 359

23.7 Other dualities . . . 361
23.8 Borel–Moore homology and fundamental classes . . . 362
23.9 Exercises . . . 362

24 Cohomology Operations **364**
24.1 Introduction . . . 364
24.2 Eilenberg–MacLane spaces . . . 364
24.3 Cohomology operations . . . 365
24.4 Steenrod squares . . . 365
24.5 Cohomology of Eilenberg–MacLane spaces . . . 367
24.6 Complex cobordism and algebraic cycles . . . 367
24.7 Exercises . . . 367

IV Sheaves **369**

25 Sheaves on Topological Spaces **370**
25.1 Introduction . . . 370
25.2 Presheaves and sheaves . . . 370
25.3 Sheafification . . . 372
25.4 Direct and inverse images . . . 373
25.5 Locally constant sheaves and local systems . . . 374
25.6 Ringed spaces and sheaves of modules . . . 375
25.7 Exercises . . . 376

26 Sheaf Cohomology **377**
26.1 Introduction . . . 377
26.2 Cohomology as a derived functor . . . 377
26.3 Flasque sheaves . . . 378
26.4 Soft and fine sheaves . . . 378
26.5 Čech cohomology . . . 380
26.6 Comparison with singular cohomology . . . 381
26.7 Hypercohomology and the Leray spectral sequence . . . 381
26.8 Cohomology with compact supports . . . 382
26.9 Exercises . . . 382

V Analysis **384**

27 Real Analysis **385**
27.1 Introduction . . . 385
27.2 Limits of sequences . . . 385
27.3 Limits of functions . . . 389
27.4 Continuous functions of a real variable . . . 391
27.5 Upper and lower limits, and series . . . 394
27.6 Differentiation in one variable . . . 398
27.7 The exponential and trigonometric functions . . . 401
27.8 The Riemann integral . . . 404
27.9 Sequences of functions . . . 407
27.10 Derivatives in several variables . . . 408
27.11 Curves, arc length and line integrals . . . 410

27.11.1 Curves and their length . . . 410
27.11.2 Line integrals of the first kind . . . 413
27.11.3 Line integrals of the second kind . . . 414
27.12 The inverse and implicit function theorems . . . 415
27.13 Extrema in several variables, Lagrange multipliers and the Karush–Kuhn–Tucker conditions . . . 416
27.13.1 Gradient and Hessian . . . 417
27.13.2 Lagrange multipliers . . . 418
27.13.3 Second-order conditions . . . 420
27.13.4 Inequality constraints and Farkas' lemma . . . 421
27.13.5 Convex problems . . . 423
27.14 Ordinary differential equations . . . 425
27.15 Stone–Weierstrass and Arzelà–Ascoli . . . 426
27.16 Exercises . . . 427

28 Measure and Integration **432**
28.1 Introduction . . . 432
28.2 Measures . . . 433
28.3 Outer measures and Lebesgue measure . . . 434
28.4 The integral . . . 436
28.5 Lebesgue spaces . . . 440
28.6 Modes of convergence . . . 441
28.7 Independence and the Borel–Cantelli lemmas . . . 442
28.8 Littlewood's principles and Lusin's theorem . . . 445
28.9 Differentiation of integrals . . . 446
28.10 Product measures and Fubini's theorem . . . 449
28.11 Change of variables . . . 450
28.11.1 Volumes: Cavalieri's principle and solids of revolution . . . 451
28.12 The Radon–Nikodym and Riesz representation theorems . . . 453
28.13 Absolutely continuous functions . . . 455
28.14 Radon measures and the Riesz representation theorem . . . 456
28.14.1 Signed and vector-valued functionals . . . 459
28.15 Weak convergence of measures . . . 464
28.16 Differentiation of measures . . . 467
28.17 Hausdorff measures . . . 469
28.18 Self-similar sets . . . 473
28.18.1 Box-counting dimension . . . 473
28.18.2 Iterated function systems . . . 475
28.18.3 The similarity dimension . . . 476
28.19 Lipschitz maps and Rademacher's theorem . . . 479
28.20 The area formula . . . 481
28.21 The coarea formula . . . 484
28.22 Densities and rectifiability . . . 487
28.22.1 Densities of measures . . . 492
28.22.2 Differentiation with respect to doubling measures . . . 494
28.23 Exercises . . . 498

29 Complex Analysis **505**
29.1 Introduction . . . 505
29.2 Holomorphic functions . . . 505
29.3 Cauchy's theorem . . . 508
29.4 The Cauchy integral formula . . . 510
29.5 Singularities, Laurent series and residues . . . 515
29.6 Conformal maps and the Riemann mapping theorem . . . 517
29.7 The Riemann sphere . . . 519
29.7.1 The sphere and stereographic projection . . . 519
29.7.2 Meromorphic functions on the sphere . . . 520
29.7.3 Möbius transformations . . . 522
29.7.4 Fixed points and conjugacy classes . . . 524
29.7.5 The disc, the half-plane and the sphere . . . 524
29.8 Exercises . . . 526

30 Functional Analysis **529**
30.1 Introduction . . . 529
30.2 Banach spaces and bounded operators . . . 529
30.3 Hilbert spaces . . . 531
30.4 The Hahn–Banach and Baire theorems . . . 533
30.5 Applications of the Baire theorems . . . 534
30.5.1 Divergence of Fourier series . . . 534
30.6 Compact operators . . . 537
30.7 The spectrum of a bounded operator . . . 539
30.8 Fréchet spaces . . . 542
30.9 Weak topologies . . . 543
30.10 Convexity and the geometric Hahn–Banach theorem . . . 544
30.11 Dual spaces and reflexivity . . . 546
30.11.1 Weak compactness: the theorems of Goldstine and Kakutani . . . 548
30.12 Exercises . . . 551

31 Several Complex Variables **555**
31.1 Introduction . . . 555
31.2 Holomorphic functions of several variables . . . 555
31.3 The Weierstrass theorems . . . 557
31.4 The Dolbeault–Grothendieck lemma . . . 559
31.5 Analytic sets . . . 560
31.6 Exercises . . . 560

32 Distributions and Sobolev Spaces **562**
32.1 Introduction . . . 562
32.2 Distributions . . . 562
32.3 The Fourier transform . . . 563
32.4 Sobolev spaces . . . 565
32.4.1 Poincaré inequalities . . . 566
32.5 Elliptic estimates . . . 570
32.6 Exercises . . . 570

VI Differential Geometry **572**

33 Smooth Manifolds **573**
33.1 Introduction . . . 573
33.2 Charts, atlases and smooth structures . . . 574
33.3 Smooth maps . . . 578
33.4 Tangent vectors . . . 582
33.5 The tangent bundle and vector fields . . . 586
33.6 Submanifolds . . . 588
33.7 Constructions of smooth manifolds . . . 595
33.8 Partitions of unity . . . 596
33.9 Vector fields and flows . . . 598
33.10 Surfaces in three- and four-dimensional space . . . 601
33.11 Manifolds of finite regularity . . . 603
33.12 Exercises . . . 604

34 Lie Groups **608**
34.1 Introduction . . . 608
34.2 Lie groups and their Lie algebras . . . 609
34.3 The exponential map . . . 612
34.4 Subgroups and homogeneous spaces . . . 616
34.5 Compact Lie groups . . . 619
34.6 The Lie correspondence: Ado's theorem and Lie's third theorem . . . 620
34.6.1 Lie subgroups . . . 621
34.6.2 Covering groups and homomorphisms . . . 622
34.6.3 Ado's theorem . . . 623
34.6.4 Lie's third theorem . . . 624
34.7 Exercises . . . 625

35 Vector Bundles **628**
35.1 Introduction . . . 628
35.2 Vector bundles and cocycles . . . 629
35.3 Operations on bundles . . . 632
35.4 Line bundles and the first Chern class . . . 639
35.5 Parallelizable manifolds . . . 641
35.6 Exercises . . . 642

36 Differential Forms and Integration **645**
36.1 Introduction . . . 645
36.2 Differential forms . . . 646
36.2.1 Forms and their coefficients in charts . . . 646
36.2.2 The wedge product . . . 648
36.2.3 Pullback along smooth maps . . . 649
36.2.4 The exterior derivative . . . 651
36.2.5 Closed and exact forms, line integrals . . . 653
36.2.6 Interior product and Lie derivative . . . 654
36.3 Orientations . . . 655
36.4 Integration and Stokes' theorem . . . 656
36.5 Exercises . . . 659

37 de Rham Cohomology **663**
37.1 Introduction . . . 663
37.2 The de Rham complex . . . 664
37.3 The de Rham theorem . . . 667
37.4 Currents . . . 672
37.4.1 Definition and first examples . . . 672
37.4.2 Support and operations . . . 674
37.4.3 Boundaries and the angle form . . . 675
37.4.4 The cohomology of currents . . . 676
37.4.5 Currents in complex geometry and in geometric measure theory . . . 677
37.5 Exercises . . . 678

38 Connections and Curvature **682**
38.1 Introduction . . . 682
38.2 Bundle-valued forms . . . 683
38.3 Connections . . . 687
38.4 Curvature . . . 691
38.5 Parallel transport, holonomy and flatness . . . 694
38.6 Metric connections . . . 699
38.7 Vertical and horizontal subspaces . . . 700
38.8 Principal bundles . . . 703
38.8.1 The curvature of a principal connection . . . 705
38.9 Exercises . . . 708

39 Characteristic Classes **711**
39.1 Introduction . . . 711
39.2 Chern–Weil theory . . . 712
39.3 Chern classes: axioms and the splitting principle . . . 714
39.4 The Thom isomorphism in de Rham cohomology . . . 715
39.5 Euler, Pontryagin and Stiefel–Whitney classes . . . 718
39.6 The Euler form and the Gauss–Bonnet–Chern theorem . . . 719
39.7 Stiefel–Whitney classes and Wu's formula . . . 727
39.8 Exercises . . . 729

40 Riemannian Geometry **732**
40.1 Introduction . . . 732
40.2 Metrics and the Levi-Civita connection . . . 733
40.3 Volume and integration . . . 734
40.4 Covariant derivatives along curves . . . 743
40.5 Gradient, Hessian, divergence and Laplacian . . . 744
40.6 The exponential map and minimising geodesics . . . 746
40.7 Parallel transport and holonomy . . . 750
40.8 Curvature . . . 752
40.9 Moving frames . . . 755
40.10 The first and second variation of energy . . . 761
40.11 Submanifolds and the second fundamental form . . . 768
40.11.1 The Gauss formula . . . 769
40.11.2 The shape operator and the curvatures of a hypersurface . . . 772
40.11.3 The equations of Gauss and Codazzi . . . 773
40.11.4 Totally geodesic and totally umbilical submanifolds . . . 774
40.11.5 Surfaces and hypersurfaces in coordinates . . . 775

40.11.6 Computing the second fundamental form . . . 777
40.12 Global theorems on surfaces . . . 780
40.13 Minimal surfaces . . . 785
40.14 The Laplace–Beltrami operator . . . 792
40.15 The Hodge star and the Laplacian . . . 795
40.16 Isometries, Killing fields and space forms . . . 796
40.17 Geometric structures . . . 805
40.18 Exercises . . . 809

41 Symplectic Geometry **818**
41.1 Introduction . . . 818
41.2 Symplectic linear algebra . . . 819
41.3 Symplectic manifolds . . . 820
41.4 The cotangent bundle . . . 821
41.5 Hamiltonian vector fields . . . 825
41.6 Darboux's theorem and Moser's method . . . 826
41.7 Lagrangian submanifolds . . . 827
41.7.1 Contact forms and Legendrian submanifolds . . . 828
41.8 Exercises . . . 832

42 Elliptic Operators on Compact Manifolds **835**
42.1 Introduction . . . 835
42.2 Differential operators and symbols . . . 836
42.3 Sobolev spaces of sections . . . 838
42.4 Elliptic estimates and regularity . . . 839
42.5 Fredholm theory and the spectral decomposition . . . 840
42.5.1 Variational description of the eigenvalues . . . 843
42.5.2 Counting eigenvalues . . . 844
42.6 Exercises . . . 844

43 Harmonic Forms and the Hodge Theorem **847**
43.1 Introduction . . . 847
43.2 The Hodge decomposition . . . 847
43.3 Applications . . . 850
43.4 Exercises . . . 853

VII Complex Geometry **856**

44 Complex Manifolds **857**
44.1 Introduction . . . 857
44.2 Complex manifolds . . . 857
44.3 Meromorphic forms and the residue theorem . . . 859
44.4 Uniformisation of Riemann surfaces . . . 862
44.5 Almost complex structures and forms of type (p, q) . . . 865
44.6 Analytic subvarieties and blow-ups . . . 866
44.7 Exercises . . . 867

45 Holomorphic Vector Bundles **869**
45.1 Introduction . . . 869
45.2 Holomorphic bundles and sheaves . . . 869
45.3 The holomorphic tangent and cotangent bundles . . . 871
45.4 Divisors . . . 874
45.5 Hermitian metrics and the Chern connection . . . 875
45.6 The canonical bundle and adjunction . . . 876
45.7 Exercises . . . 876

46 Dolbeault Cohomology **878**
46.1 Introduction . . . 878
46.2 The Dolbeault theorem . . . 878
46.3 Harmonic theory for $\bar{\partial}$ . . . 880
46.4 Examples and the Frölicher inequality . . . 881
46.5 Exercises . . . 882

47 Kähler Manifolds **883**
47.1 Introduction . . . 883
47.2 Hermitian metrics and the fundamental form . . . 883
47.3 The Kähler condition . . . 884
47.4 Examples . . . 885
47.5 Linear algebra of the Lefschetz operator . . . 888
47.6 Exercises . . . 889

48 The Hodge Decomposition **891**
48.1 Introduction . . . 891
48.2 Conventions . . . 891
48.3 The Kähler identities . . . 892
48.4 Comparison of Laplacians . . . 893
48.5 The Hodge decomposition . . . 894
48.6 The $\partial\bar{\partial}$-lemma . . . 896
48.7 Examples . . . 897
48.8 Exercises . . . 898

49 Hard Lefschetz and the Hodge–Riemann Relations **900**
49.1 Introduction . . . 900
49.2 The $\mathfrak{sl}_2$-action on cohomology . . . 900
49.3 Pointwise Hodge–Riemann relations . . . 902
49.4 The Hodge–Riemann bilinear relations . . . 903
49.5 The Hodge index theorem . . . 904
49.6 Further remarks and counterexamples . . . 905
49.7 Exercises . . . 906

50 Vanishing and Embedding Theorems **907**
50.1 Introduction . . . 907
50.2 Positive line bundles . . . 907
50.3 The Bochner–Kodaira–Nakano identity . . . 909
50.4 The Kodaira–Nakano vanishing theorem . . . 910
50.5 The Lefschetz hyperplane theorem . . . 911
50.6 The Kodaira embedding theorem . . . 912
50.7 Exercises . . . 915

51 Deformations and Moduli **916**
51.1 Introduction . . . 916
51.2 Families of complex manifolds . . . 917
51.3 The moduli space of elliptic curves . . . 918
51.4 The Kodaira–Spencer map . . . 920
51.5 Kuranishi theory and moduli spaces . . . 923
51.6 Exercises . . . 924

52 Calabi–Yau Manifolds **926**
52.1 Introduction . . . 926
52.2 The Ricci form . . . 926
52.3 The Calabi conjecture . . . 927
52.4 Calabi–Yau manifolds and their Hodge numbers . . . 927
52.5 Structure and symmetries . . . 929
52.6 Exercises . . . 930

VIII Algebraic Geometry **931**

53 Algebraic Varieties **932**
53.1 Introduction . . . 932
53.2 Affine algebraic sets and the Zariski topology . . . 932
53.3 Regular functions and morphisms . . . 933
53.4 Projective varieties . . . 935
53.5 Dimension . . . 937
53.6 Tangent spaces and smoothness . . . 938
53.7 Rational maps and birational equivalence . . . 939
53.8 Blow-ups . . . 940
53.9 Exercises . . . 941

54 Schemes **943**
54.1 Introduction . . . 943
54.2 The spectrum of a ring . . . 943
54.3 Schemes and their properties . . . 945
54.4 Fibre products . . . 946
54.5 Separated and proper morphisms . . . 946
54.6 Projective schemes . . . 947
54.7 Varieties as schemes . . . 948
54.8 Flat and smooth morphisms . . . 948
54.9 Base change and varieties over non-closed fields . . . 950
54.10 Exercises . . . 950

55 Quasi-coherent and Coherent Sheaves **952**
55.1 Introduction . . . 952
55.2 The sheaf associated to a module . . . 952
55.3 Quasi-coherent sheaves . . . 953
55.4 Locally free sheaves and the Picard group . . . 955
55.5 Twisting sheaves on projective schemes . . . 955
55.6 Sheaves of differentials . . . 956
55.7 Exercises . . . 957

56 Cohomology of Coherent Sheaves **959**
56.1 Introduction . . . 959
56.2 Vanishing on affine schemes . . . 959
56.3 The cohomology of projective space . . . 961
56.4 Finiteness and Serre vanishing . . . 961
56.5 Euler characteristic and Hilbert polynomial . . . 962
56.6 Serre duality . . . 963
56.7 Semicontinuity and base change . . . 963
56.8 Exercises . . . 964

57 Divisors and Line Bundles **965**
57.1 Introduction . . . 965
57.2 Weil divisors . . . 965
57.3 Cartier divisors and invertible sheaves . . . 966
57.4 Linear systems and morphisms to projective space . . . 967
57.5 Ample line bundles . . . 967
57.6 Intersection numbers on surfaces . . . 968
57.7 The Néron–Severi group . . . 969
57.8 Exercises . . . 970

58 Analytic Spaces and GAGA **971**
58.1 Introduction . . . 971
58.2 Complex analytic spaces . . . 971
58.3 The analytification functor . . . 972
58.4 Chow's theorem and GAGA . . . 972
58.5 Algebraic de Rham cohomology . . . 974
58.6 Smooth projective varieties as Kähler manifolds . . . 975
58.7 Exercises . . . 975

59 Algebraic Curves and Riemann Surfaces **976**
59.1 Introduction . . . 976
59.2 Curves and their function fields . . . 976
59.3 The Riemann–Roch theorem . . . 978
59.4 The Riemann–Hurwitz formula . . . 978
59.5 Hyperelliptic curves and the canonical embedding . . . 979
59.6 The Jacobian and the Abel–Jacobi theorem . . . 980
59.7 Exercises . . . 981

60 Linear Algebraic Groups **982**
60.1 Introduction . . . 982
60.2 Affine group schemes . . . 982
60.3 Representations and Tannakian categories . . . 983
60.4 Tori, characters and the Deligne torus . . . 984
60.5 The Lie algebra . . . 985
60.6 Reductive groups . . . 985
60.7 Weil restriction of scalars . . . 986
60.8 Exercises . . . 986

61 Abelian Varieties **988**
61.1 Introduction . . . 988
61.2 Complex tori and their cohomology . . . 988
61.3 Line bundles and the Riemann conditions . . . 989
61.4 The dual abelian variety . . . 991
61.5 Jacobians . . . 991
61.6 Endomorphisms and complex multiplication . . . 992
61.7 Exercises . . . 992

62 Algebraic Cycles and Chow Groups **994**
62.1 Introduction . . . 994
62.2 Cycles and rational equivalence . . . 994
62.3 Functoriality . . . 996
62.4 Chern classes and the intersection product . . . 996
62.5 Correspondences . . . 997
62.6 Adequate equivalence relations . . . 997
62.7 Riemann–Roch . . . 998
62.8 Exercises . . . 999

63 The Cycle Class Map **1000**
63.1 Introduction . . . 1000
63.2 Fundamental classes . . . 1000
63.3 The cycle class map and its properties . . . 1001
63.4 Cycle classes are Hodge classes . . . 1002
63.5 Cycles and coherent sheaves . . . 1003
63.6 Exercises . . . 1003

64 Index Theorems and Riemann–Roch **1004**
64.1 Introduction . . . 1004

Chapter 1

Introduction

1.1 What this project is

The Hodge Project is a cumulative reference whose goal is to develop, with complete proofs, all the mathematics needed to state, understand and work with the Hodge conjecture, together with the theory that surrounds it.

Informally, the Hodge conjecture says the following: on a smooth complex projective variety X, every rational cohomology class of type (p, p) is a rational linear combination of the classes of algebraic subvarieties of X. A precise statement is given in Chapter 68. Each word of the informal statement hides a substantial theory: rational cohomology classes come from algebraic topology (Chapter 22), the type (p, p) comes from the Hodge decomposition of a compact Kähler manifold (Chapter 48), which rests on the analysis of elliptic operators (Chapter 42), and the classes of subvarieties come from algebraic geometry (Chapters 53 and 63). This project builds all of it, starting from logic and set theory.

The organisation is modelled on the Stacks project: the text is written in a strict logical order, every result has a permanent tag, and the whole project is a single document that can be read as a book or browsed as a website.

1.2 How the project is organised

The chapters are grouped into parts.

- Part I, *Foundations*: logic, set theory, the number systems and category theory.
- Part II, *Algebra*: from groups to derived categories, including a chapter of elementary number theory.
- Part III, *Topology*: general topology, homotopy theory, singular homology and cohomology, Poincaré duality.
- Part IV, *Sheaves*: sheaves and sheaf cohomology.
- Part V, *Analysis*: real, complex and functional analysis, several complex variables and Sobolev spaces.
- Part VI, *Differential Geometry*: from smooth manifolds to the Hodge theorem for harmonic forms.
- Part VII, *Complex Geometry*: complex and Kähler manifolds, the Hodge decomposition, the Lefschetz theorems, the Kodaira vanishing and embedding theorems, deformations of complex structures and moduli, and Calabi–Yau manifolds.

- Part VIII, *Algebraic Geometry*: varieties, schemes, coherent cohomology, GAGA, curves, algebraic groups, abelian varieties, algebraic cycles, the cycle class map and étale cohomology.

- Part IX, *Hodge Theory*: Hodge structures and Mumford–Tate groups, the Hodge conjecture, the evidence for it, its failed variants, mixed Hodge structures, absolute Hodge classes, and the Tate and standard conjectures around it.

The order of the chapters is the logical order of the project, not a recommended reading order. Section 1.3 describes how to read the book, and in particular the shortest route to the Hodge conjecture.

1.3 How to read this book

There are three ways to use the book.

- *As a reference.* Look up a result by its tag or with the search page of the website, and follow its references backwards. The **Prerequisites** line at the start of each chapter lists the chapters it depends on, and the dependency graph of the website shows, for every result, the results that its statement and proof use.

- *As a direct route to the Hodge conjecture*, reading only what is needed to understand its statement and the one case that is proved in full, the Lefschetz $(1,1)$ theorem. This route is described below.

- *As a course*, from the foundations onwards, in the order of the chapters. The book is written so that this is possible: nothing is used before it is proved (Remark 1.6.4).

1.3.1 The direct route

The direct route ends with Chapter 68, which states the conjecture, and Chapter 69, which proves it for divisors. Every chapter begins, after its Prerequisites line, with a paragraph **On the way to the Hodge conjecture**, which says which of its sections the direct route uses and which can be postponed. These paragraphs are based on the references between results, so they say what is actually used; a reader who skips a section and later meets a reference to it can go back. Part by part, the route is as follows.

- *Foundations.* Read Chapter 3 for the language of sets, functions, cardinals and Zorn's lemma, and Chapter 6 for the language of categories, functors, limits and adjoint functors. A reader who knows the real and complex numbers can skim Chapter 4. Chapters 2 and 5 are not needed.

- *Algebra.* Linear and multilinear algebra are needed in full: the complex structures of Chapter 11 and the exterior algebra and forms of type (p,q) of Chapter 12 are the linear algebra of the Hodge decomposition. From Chapters 8, 9 and 14 one needs ideals, modules and tensor products, transcendence degree, and the commutative algebra behind dimension and smoothness of varieties. Homological algebra and the spectral sequences of filtered and double complexes are needed for sheaf cohomology; derived categories only for hypercohomology. From Chapter 13 only the representations of $\mathfrak{sl}_2$ are used, for hard Lefschetz. Chapter 10, most of Chapter 7, Galois theory and the structure of semisimple Lie algebras can be postponed.

- *Topology.* General topology up to partitions of unity; homotopy, the fundamental group and covering spaces; singular homology and cohomology with cup and cap products; Poincaré duality and fundamental classes. Chapter 24 is not needed.

- *Sheaves.* Both chapters: sheaves and their images, sheaf cohomology through flasque and soft resolutions, Čech cohomology and the comparison with singular cohomology.

- *Analysis.* Real analysis up to the inverse and implicit function theorems; the Lebesgue integral, L^p spaces and Fubini's theorem; Cauchy's theorem in one and several complex variables, and the Dolbeault–Grothendieck lemma; Banach and Hilbert spaces and compact operators; Sobolev spaces. The geometric measure theory at the end of Chapter 28 and the second half of Chapter 30 are not on the route.

- *Differential geometry.* Smooth manifolds, vector bundles, differential forms and Stokes' theorem, de Rham's theorem, connections and curvature, Chern–Weil theory, the Hodge star, elliptic operators (whose estimates can be taken on faith on a first reading) and the Hodge theorem. Chapter 34, most of Chapter 40 and Chapter 41 can be postponed.

- *Complex geometry.* Complex manifolds, holomorphic bundles, Dolbeault cohomology, Kähler manifolds, the Hodge decomposition, hard Lefschetz and the Hodge–Riemann relations, positive line bundles and the Kodaira theorems. Chapters 51 and 52 are not needed.

- *Algebraic geometry.* Varieties; schemes, mainly as a language; coherent sheaves and their cohomology; divisors and line bundles; GAGA, which makes smooth projective varieties into compact Kähler manifolds; algebraic cycles and the cycle class map. Chapters 59, 61, 64 and 65 are not needed; from Chapter 60 only the Deligne torus is used.

- *Hodge theory.* The definitions of Chapter 66, then Chapters 68 and 69. The remaining chapters of the part are the surrounding theory, to be read afterwards.

1.3.2 The main line

Seen from above, the direct route has the following stages; everything else in the book supports them or grows out of them.

1. *Cohomology.* Singular cohomology and Poincaré duality (Chapters 22 and 23), sheaf cohomology (Chapter 26) and de Rham's theorem (Chapter 37) give the rational cohomology of a manifold and its description by differential forms.

2. *Harmonic theory.* Elliptic operators (Chapter 42) give the Hodge theorem: every de Rham class has a unique harmonic representative (Chapter 43).

3. *Kähler geometry.* On a compact Kähler manifold (Chapter 47) the Laplacian respects the bidegree of forms, which gives the Hodge decomposition $H^k = \bigoplus_{p+q=k} H^{p,q}$ (Chapter 48), hard Lefschetz and the Hodge–Riemann relations (Chapter 49).

4. *Algebraic geometry.* Projective varieties are Kähler, and GAGA identifies analytic and algebraic objects on them (Chapter 58). Subvarieties have cohomology classes, which are rational and of type (p, p) (Chapter 63).

5. *The conjecture.* Hodge structures (Chapter 66) isolate the linear algebra, and the Hodge conjecture asserts the converse of the last statement (Chapter 68). It is a theorem for divisors (Chapter 69), it is known in further cases (Chapter 72), and its natural strengthenings are false (Chapter 73).

6. *The surrounding theory.* Variations of Hodge structure and normal functions (Chapters 70 and 71), mixed Hodge structures (Chapter 74), absolute Hodge classes (Chapter 75), and the Tate and standard conjectures (Chapters 76 and 77) place the conjecture in its wider landscape.

Remark 1.3.1. The book also contains much material that is not needed on the way to the Hodge conjecture, and is there because it belongs to the same circle of ideas, because the book aims to be a complete guide to the mathematics around it, or because it is beautiful: model theory and number theory, geometric measure theory, Riemannian and symplectic geometry for their own sake, Calabi–Yau manifolds, curves and abelian varieties. The paragraphs **On the way to the Hodge conjecture** say where it is, and it can be read at any time after its prerequisites.

1.4 A map of the integrals

Many integrals appear in the book: the Riemann integral, the Lebesgue integral, volumes, lengths and areas, line integrals of two kinds, complex line integrals, integrals of differential forms, integrals on Riemannian manifolds and on Lie groups. They are defined where they are first needed, often by an explicit formula, but they are not independent notions. All of them are special cases of two constructions, and the second is built from the first.

1. *The integral of a function against a measure,* $\int_X f\, d\mu$ (Chapter 28, Section 28.4). It needs a measure on X, that is, a way to assign a size to subsets, and no orientation: reversing a curve does not change its length. Integrals of this kind are written with $d\mu$, dx, ds, dA or $d\mathcal{H}^k$.

2. *The integral of a differential k-form over an oriented k-dimensional manifold,* $\int_M \omega$ (Definition 36.4.1). It needs an orientation, and no measure or metric: in a positively oriented chart, $\omega = f\, dx^1 \wedge \cdots \wedge dx^k$ and $\int_M \omega$ is the Lebesgue integral $\int f\, d\lambda^k$, patched together with a partition of unity. Reversing the orientation changes the sign.

On an oriented Riemannian manifold the two meet: a k-form is a function times the volume form, and $\int_M \omega = \int_M \langle \omega, \xi \rangle\, d\mu_g$ with the orienting k-vector ξ (Proposition 40.3.10). Here is how the individual integrals of the book fit into this picture.

- *The Riemann integral* $\int_a^b f$ (Definition 27.8.1) comes first because it needs no measure theory, and it is enough for continuous functions on intervals. It is the Lebesgue integral $\int_{[a,b]} f\, d\lambda$ for every Riemann integrable f (Propositions 28.4.9 and 28.4.10), so nothing proved with it has to be redone. Vector- and complex-valued functions are integrated componentwise, $\int (u + iv) = \int u + i \int v$.

- *Multiple integrals and volumes* $\int_{\mathbb{R}^n} f\, d\lambda^n$: Lebesgue measure on $\mathbb{R}^n$, computed by Fubini's theorem and the change of variables formula (Sections 28.10 and 28.11), with Cavalieri's principle and solids of revolution as special cases (Subsection 28.11.1).

- *Length and line integrals of the first kind* $\int_\gamma f\, ds$ (Section 27.11): defined by the formula $\int_a^b f(\gamma(t))|\gamma'(t)|\, dt$. They are integrals of the first construction: for an injective regular

curve, $\int_\gamma f\,ds = \int_{\gamma([a,b])} f\,d\mathcal{H}^1$, the integral against one-dimensional Hausdorff measure on the image (Theorem 28.20.3 and Example 28.20.4(1)), which depends only on the set.

- *Areas and surface integrals* $\int_\Sigma f\,dA$: the integral against $\mathcal{H}^2$, or $\mathcal{H}^k$ for k-dimensional submanifolds, computed from a parametrisation by the area formula (Section 28.20); equivalently, the Riemannian measure of the induced metric (Propositions 40.3.2 and 40.3.6). The theorems of Pappus–Guldin are examples.
- *Line integrals of the second kind* $\int_\gamma F \cdot d\gamma$ (Definition 27.11.12): the integral of the 1-form $F_1\,dx_1 + \cdots + F_n\,dx_n$ over the oriented curve (Definition 36.2.18), an integral of the second construction. For a regular curve it is $\int_\gamma \langle F, T\rangle\,ds$, a first-kind integral of the tangential component (Proposition 27.11.13(3)): choosing the unit tangent T is choosing an orientation.
- *Complex line integrals* $\int_\gamma f\,dz$ (Definition 29.2.7): the integral of the complex-valued 1-form $f\,dz$, which splits into two real line integrals of the second kind, $\int_\gamma (u\,dx - v\,dy) + i\int_\gamma (v\,dx + u\,dy)$ (Proposition 29.2.9).
- *Flux integrals and integrals of k-forms* over oriented submanifolds, $\int_M \omega$, with Stokes' theorem (Theorem 36.4.8) and its classical cases, the theorems of Green, Gauss and Kelvin–Stokes (Chapter 40): the second construction.
- *Integrals on Riemannian manifolds* $\int_M f\,d\mu_g$, and on Lie groups against Haar measure (Theorem 34.5.1): the first construction, for the Riemannian measure and the Haar measure. On an oriented manifold, $\int_M f\,d\mu_g = \int_M f\,\mathrm{vol}_g$.
- *Integration in cohomology*: $\int_M : H^n_{\mathrm{dR}}(M) \to \mathbb{R}$ on a compact oriented manifold, periods of closed forms over cycles, and the integrals of characteristic forms that compute Chern numbers: the second construction applied to closed forms, which depends only on cohomology classes by Stokes' theorem (Chapters 37 and 39).
- *Distributions and currents* (Chapter 32 and Section 37.4) are not integrals but generalise them: a function f gives the functional $\varphi \mapsto \int f\varphi$ and a submanifold Z the functional $\varphi \mapsto \int_Z \varphi$, and the theory keeps only the functional.

In short: if an integral ignores orientation, look for the measure; if it changes sign when the orientation is reversed, it is the integral of a form. The Lebesgue integral underlies both.

1.5 Sources and status

The mathematics in this project is standard, and each chapter lists the references it follows; the bibliography collects them. The chapters of Part IX follow the original papers and the surveys cited in each of them. Where a theorem is quoted rather than proved, the text says so and gives a reference (Remark 1.6.3). All chapters are written; none has yet been checked by an independent reader, which is the condition for the status *checked* (Remark 1.6.6).

1.6 Conventions of the text

Notation 1.6.1. All numbered items of a section share a single counter: Lemma 5.2.3 is the third numbered item of Section 5.2, and it is followed by Example 5.2.4. Chapters are numbered consecutively through all the parts.

Notation 1.6.2. The text uses the following kinds of numbered items.

- **Definition**: introduces a notion.
- **Theorem**, **Proposition**, **Lemma**, **Corollary**: proved statements, in roughly decreasing order of importance.
- **Conjecture**: a statement that is not known to be true.
- **Example**: an instance of a definition or a result.
- **Counterexample**: shows that a hypothesis cannot be dropped, or that a plausible statement is false.
- **Remark**: context, motivation or intuition. Remarks are never used in proofs.
- **Notation**: fixes notation or a convention.
- **Exercise**: a statement for the reader to prove, sometimes followed by a solution.

Remark 1.6.3. A result followed by *Proof* has a complete proof that uses only earlier material. A result followed by *Sketch of proof* has an argument whose main ideas are given but whose omitted verifications are named. A result followed by no proof is quoted from the literature, with a reference. Sketches and quotations are temporary: the aim of the project is to replace all of them with complete proofs.

Remark 1.6.4. The project has no forward references: a proof may only use definitions and results that appear before it. Examples, counterexamples, remarks and exercises may mention notions that are defined later (for instance, the category of topological spaces appears as an example in Chapter 6), but such mentions are never used in a proof. The only exception is this introduction, which refers forward freely.

Remark 1.6.5. Every labelled item (chapter, section, definition, result, example, and so on) carries a permanent four-character *tag*, shown next to it on the website. The number of an item changes whenever material is inserted before it; its tag never changes. To refer to an item from outside the project, cite its tag.

Remark 1.6.6. Each chapter has a status. *Planned*: only an outline exists. *Draft*: the chapter is being written, and its proofs have not been checked. *Complete*: all planned material is written, and the proofs await independent checking. *Checked*: every proof in the chapter has been checked by a reader other than its author.

1.7 Mathematical conventions

Notation 1.7.1. We work in ZFC set theory together with the assumption that a Grothendieck universe exists, and we fix such a universe $\mathcal{U}$ once and for all. A set is *small* if it is an element of $\mathcal{U}$. Chapter 3 develops these notions; Chapter 6 explains why they are needed.

Notation 1.7.2. The natural numbers include zero: $\mathbb{N} = \{0, 1, 2, \ldots\}$. This is the convention of set theory and logic, where $\mathbb{N}$ is built starting from $0 = \emptyset$ and each natural number $n = \{0, 1, \ldots, n-1\}$ is a set with n elements (Remark 3.4.3). Many texts, especially in analysis and number theory, start from 1 instead; for the positive integers we write $\mathbb{N}_{>0} = \{1, 2, 3, \ldots\}$, and more generally $\mathbb{N}_{\geq k} = \{k, k+1, \ldots\}$. A real number x is *positive* if $x > 0$ and *non-negative* if $x \geq 0$.

Notation 1.7.3. The composition of maps $f\colon X \to Y$ and $g\colon Y \to Z$ is written $g \circ f$ or gf. The identity map of X is written id_X.

Notation 1.7.4. A ring is associative and has an identity element 1, and ring homomorphisms preserve identity elements. Rings are not assumed to be commutative, except from Chapter 14 onwards, where "ring" means "commutative ring" unless stated otherwise.

Foundations

Chapter 2

Mathematical Logic

2.1 Introduction

Mathematical logic studies the language in which mathematics is written: what a formula is, what it means for a formula to be true in a structure, and what it means to prove it. The main result of this chapter is Gödel's completeness theorem (Theorem 2.6.1 and Corollary 2.6.2): a statement follows from a set of axioms in every structure if and only if it can be formally deduced from them. Its consequences, the compactness and Löwenheim–Skolem theorems, are the first tools of model theory. We end with the statements of Gödel's incompleteness theorems, which limit what any axiomatic foundation, including the set theory of Chapter 3, can prove about itself.

We follow the approach of [End01]; other references are [Sho67] and [vD13], and [CK90] for model theory.

Prerequisites. None.

On the way to the Hodge conjecture. This chapter is not needed. It provides the formal foundation of set theory (Chapter 3) and the basis of model theory (Chapter 5); a reader comfortable with the usual informal use of sets and logic can skip it and come back to it later.

Remark 2.1.1. This chapter studies formal languages *from the outside*. The reasoning we use about formulas, structures and deductions (induction on the natural numbers, finite sequences, sets, countability) is ordinary informal mathematics, sometimes called the *metatheory*. In Chapter 3, set theory is itself formulated as a first-order theory in the sense of this chapter. There is no vicious circle: informal mathematics is used to describe formal systems, and one of these formal systems is then used as the official foundation of the rest of the project. The proofs in this chapter use only elementary facts about finite and countable sets, and in particular never the axiom of choice.

2.2 Propositional logic

Definition 2.2.1. Let P be a set, whose elements we call *propositional variables*, and let $\neg$, $\to$, (and) be four symbols not in P. A *string* is a finite sequence of symbols. The set of *propositional formulas* over P is the smallest set of strings such that

1. every $p \in P$, viewed as a string of length one, is a formula;
2. if φ is a formula, then $\neg\varphi$ is a formula;
3. if φ and ψ are formulas, then $(\varphi \to \psi)$ is a formula.

Here $\neg\varphi$ denotes the string consisting of $\neg$ followed by the symbols of φ, and similarly for $(\varphi \to \psi)$.

Remark 2.2.2. Every formula is obtained from propositional variables by finitely many applications of the two operations, since the set of such strings contains P and is closed under the operations. Hence statements about all formulas can be proved by *induction on formulas*: it suffices to prove them for propositional variables and to show that they are preserved by the two operations.

Notation 2.2.3. We use the abbreviations $(\varphi \wedge \psi) := \neg(\varphi \to \neg\psi)$, $(\varphi \vee \psi) := (\neg\varphi \to \psi)$ and $(\varphi \leftrightarrow \psi) := ((\varphi \to \psi) \wedge (\psi \to \varphi))$, and we omit outer parentheses when no confusion is possible.

Lemma 2.2.4. *Let φ be a propositional formula. Then φ contains as many symbols (as symbols). Moreover, every proper initial segment of φ either consists only of symbols $\neg$ (possibly none), or contains strictly more symbols (than symbols).*

Proof. For a string u let $b(u)$ be the number of symbols (in u minus the number of symbols) in u. We argue by induction on φ.

If $\varphi = p$ is a variable, then $b(p) = 0$ and the only proper initial segment is empty.

If $\varphi = \neg\psi$, then $b(\varphi) = b(\psi) = 0$. A proper initial segment of φ is empty or of the form $\neg u$ with u a proper initial segment of ψ. By induction, u consists of symbols $\neg$ or $b(u) > 0$, and the same holds for $\neg u$.

If $\varphi = (\psi \to \chi)$, then $b(\varphi) = 1 + b(\psi) + b(\chi) - 1 = 0$. A nonempty proper initial segment of φ has one of the forms (u with u an initial segment of ψ, or ($\psi \to u$ with u an initial segment of χ (possibly empty or equal to χ). By induction every initial segment u of ψ or χ satisfies $b(u) \geq 0$, so these segments have $b \geq 1$. □

Theorem 2.2.5 (Unique readability)**.** *Every propositional formula φ satisfies exactly one of the following: φ is a propositional variable; $\varphi = \neg\psi$ for a formula ψ; $\varphi = (\psi \to \chi)$ for formulas ψ and χ. In the second case ψ is uniquely determined, and in the third case ψ and χ are uniquely determined.*

Proof. The three cases are distinguished by the first symbol of φ, and in the second case ψ is φ with its first symbol removed. Suppose $(\psi \to \chi) = (\psi' \to \chi')$ with $\psi \neq \psi'$. After the first symbol the two strings agree, so one of ψ, ψ' is a proper initial segment of the other, say ψ of ψ'. By Lemma 2.2.4, $b(\psi) = 0$, so ψ must consist only of symbols $\neg$. But every formula contains at least one propositional variable (by induction on formulas), a contradiction. Hence $\psi = \psi'$, and then $\chi = \chi'$. □

Definition 2.2.6. A *truth assignment* is a map $v\colon P \to \{0,1\}$. By Theorem 2.2.5, there is a unique map $\bar{v}$ from the set of formulas to $\{0,1\}$, defined by recursion on formulas, such that $\bar{v}(p) = v(p)$ for $p \in P$, $\bar{v}(\neg\varphi) = 1 - \bar{v}(\varphi)$, and $\bar{v}(\varphi \to \psi) = 0$ if and only if $\bar{v}(\varphi) = 1$ and $\bar{v}(\psi) = 0$. We say that v *satisfies* φ if $\bar{v}(\varphi) = 1$, and that v satisfies a set of formulas Σ if it satisfies every element of Σ.

Definition 2.2.7. A formula φ is a *tautology* if every truth assignment satisfies it. A set Σ of formulas *tautologically implies* φ, written $\Sigma \models \varphi$, if every truth assignment satisfying Σ satisfies φ. A set of formulas is *satisfiable* if some truth assignment satisfies it.

Lemma 2.2.8. *For every truth assignment v: $\bar{v}(\varphi \wedge \psi) = 1$ if and only if $\bar{v}(\varphi) = \bar{v}(\psi) = 1$; $\bar{v}(\varphi \vee \psi) = 1$ if and only if $\bar{v}(\varphi) = 1$ or $\bar{v}(\psi) = 1$; and $\bar{v}(\varphi \leftrightarrow \psi) = 1$ if and only if $\bar{v}(\varphi) = \bar{v}(\psi)$.*

Proof. $\bar{v}(\neg(\varphi \to \neg\psi)) = 1$ if and only if $\bar{v}(\varphi \to \neg\psi) = 0$, that is, $\bar{v}(\varphi) = 1$ and $\bar{v}(\neg\psi) = 0$. Next, $\bar{v}(\neg\varphi \to \psi) = 0$ if and only if $\bar{v}(\varphi) = 0$ and $\bar{v}(\psi) = 0$. The last statement follows from the first and the definition of $\bar{v}$ on implications. □

Example 2.2.9. The following are tautologies, as one checks by computing $\bar{v}$ for the finitely many possible values of v on the variables involved: $\varphi \vee \neg\varphi$ (excluded middle); $\neg\neg\varphi \leftrightarrow \varphi$; $((\varphi \to \psi) \to \varphi) \to \varphi$ (Peirce's law); $\neg(\varphi \wedge \psi) \leftrightarrow (\neg\varphi \vee \neg\psi)$ (De Morgan); $(\varphi \to (\psi \to \chi)) \to ((\varphi \to \psi) \to (\varphi \to \chi))$. By contrast, $(\varphi \to \psi) \to (\psi \to \varphi)$ is not a tautology when φ and ψ are distinct variables.

Proposition 2.2.10. *Let $p_1, \dots, p_n$ be distinct propositional variables, $n \geq 1$, and let $F\colon \{0,1\}^n \to \{0,1\}$ be any function. There is a formula φ whose variables are among $p_1, \dots, p_n$ such that $\bar{v}(\varphi) = F(v(p_1), \dots, v(p_n))$ for every truth assignment v.*

Proof. For $\varepsilon \in \{0,1\}^n$ let $\gamma_\varepsilon = \ell_1 \wedge \cdots \wedge \ell_n$, where $\ell_i = p_i$ if $\varepsilon_i = 1$ and $\ell_i = \neg p_i$ if $\varepsilon_i = 0$ (with parentheses grouped to the left). By Lemma 2.2.8, $\bar{v}(\gamma_\varepsilon) = 1$ if and only if $v(p_i) = \varepsilon_i$ for all i. If F is identically 0, take $\varphi = p_1 \wedge \neg p_1$. Otherwise let φ be the disjunction of the γ_ε over all ε with $F(\varepsilon) = 1$. Then $\bar{v}(\varphi) = 1$ if and only if $(v(p_1), \dots, v(p_n))$ is one of these ε, that is, if and only if $F(v(p_1), \dots, v(p_n)) = 1$. □

Counterexample 2.2.11. Proposition 2.2.10 fails if only $\wedge$ and $\vee$ may be used, taken as primitive connectives with the truth tables of Lemma 2.2.8. Indeed, by induction on such formulas, if $v(p) \leq w(p)$ for every variable p then $\bar{v}(\varphi) \leq \bar{w}(\varphi)$. So no such formula computes the function $F(x) = 1 - x$.

Theorem 2.2.12 (Compactness, propositional case)**.** *Let P be countable and let Σ be a set of formulas over P. If every finite subset of Σ is satisfiable, then Σ is satisfiable.*

Proof. Call a set of formulas *finitely satisfiable* if all its finite subsets are satisfiable. The formulas are finite strings over a countable set of symbols, so they can be enumerated as $\varphi_0, \varphi_1, \dots$. Put $\Delta_0 = \Sigma$, and let $\Delta_{n+1} = \Delta_n \cup \{\varphi_n\}$ if this set is finitely satisfiable, and $\Delta_{n+1} = \Delta_n \cup \{\neg\varphi_n\}$ otherwise.

Each Δ_n is finitely satisfiable. Suppose Δ_n is, but neither $\Delta_n \cup \{\varphi_n\}$ nor $\Delta_n \cup \{\neg\varphi_n\}$ is. Then there are finite $\Delta, \Delta' \subseteq \Delta_n$ such that $\Delta \cup \{\varphi_n\}$ and $\Delta' \cup \{\neg\varphi_n\}$ are not satisfiable. A truth assignment v satisfying $\Delta \cup \Delta'$ satisfies φ_n or $\neg\varphi_n$, hence one of the two sets; contradiction.

Let $\Delta = \bigcup_n \Delta_n$. Every finite subset of Δ lies in some Δ_n, so Δ is finitely satisfiable; in particular Δ never contains both ψ and $\neg\psi$. For every formula ψ, exactly one of $\psi, \neg\psi$ lies in Δ. Define $v(p) = 1$ if and only if $p \in \Delta$. We show by induction on ψ that $\bar{v}(\psi) = 1$ if and only if $\psi \in \Delta$. For variables this is the definition. For $\neg\psi$: $\bar{v}(\neg\psi) = 1$ iff $\psi \notin \Delta$ iff $\neg\psi \in \Delta$. For $\psi \to \chi$: if $(\psi \to \chi) \in \Delta$, $\psi \in \Delta$ and $\chi \notin \Delta$, then $\neg\chi \in \Delta$ and the finite set $\{\psi \to \chi, \psi, \neg\chi\}$ is not satisfiable. If $(\psi \to \chi) \notin \Delta$, then $\neg(\psi \to \chi) \in \Delta$; if moreover $\psi \notin \Delta$ or $\chi \in \Delta$, then Δ contains $\{\neg(\psi \to \chi), \neg\psi\}$ or $\{\neg(\psi \to \chi), \chi\}$, neither of which is satisfiable. So $(\psi \to \chi) \in \Delta$ if and only if $\psi \notin \Delta$ or $\chi \in \Delta$, which by induction is equivalent to $\bar{v}(\psi \to \chi) = 1$. Hence v satisfies $\Delta \supseteq \Sigma$. □

Remark 2.2.13. The theorem holds for arbitrary sets P, but the proof then needs a form of the axiom of choice (for instance Zorn's lemma, Chapter 3) to replace the enumeration of all formulas.

2.3 First-order languages

Definition 2.3.1. A *first-order language* $\mathcal{L}$ consists of a set of *constant symbols*, and for each $n \geq 1$ a set of n-ary *function symbols* and a set of n-ary *relation symbols*, all these sets being pairwise disjoint. The language is *countable* if the union of these sets is countable. Every language also has the *logical symbols*: a countably infinite set of *variables* $v_0, v_1, v_2, \dots$, disjoint from the other symbols, and the symbols $=$, $\neg$, $\to$, $\forall$.

Definition 2.3.2. Let $\mathcal{L}$ be a language. The set of *terms* is the smallest set that contains the variables and the constant symbols and contains the tuple $(f, t_1, \dots, t_n)$ whenever f is an n-ary function symbol and $t_1, \dots, t_n$ are terms. We write $f(t_1, \dots, t_n)$ for this tuple.

The *atomic formulas* are the tuples $(=, t_1, t_2)$ and $(R, t_1, \dots, t_n)$, where the t_i are terms and R is an n-ary relation symbol; we write $t_1 = t_2$ and $R(t_1, \dots, t_n)$. The set of *formulas* is the smallest set that contains the atomic formulas and contains $(\neg, \varphi)$, $(\to, \varphi, \psi)$ and $(\forall, x, \varphi)$ whenever φ, ψ are formulas and x is a variable. We write $\neg\varphi$, $(\varphi \to \psi)$ and $\forall x\, \varphi$ for these tuples.

Remark 2.3.3. We assume, as we may, that no symbol is itself a finite tuple of the above shapes. Since two tuples are equal only if they have the same length and the same entries, every term and every formula decomposes *uniquely* into its immediate constituents. This is the analogue of Theorem 2.2.5, obtained here for free: we have defined formulas as trees rather than strings. As in Remark 2.2.2, we can prove statements by induction on terms and formulas, and define functions on them by recursion. The *complexity* $c(\varphi)$ of a formula is the number of occurrences of $\neg$, $\to$ and $\forall$ in it: $c = 0$ on atomic formulas, $c(\neg\varphi) = c(\varphi) + 1$, $c(\varphi \to \psi) = c(\varphi) + c(\psi) + 1$ and $c(\forall x\, \varphi) = c(\varphi) + 1$.

In practice we write formulas as usual, for instance $x \cdot y = y \cdot x$ instead of $(=, (\cdot, x, y), (\cdot, y, x))$, and we use variables named $x, y, z, \dots$ for arbitrary distinct variables.

Notation 2.3.4. Besides the abbreviations of Notation 2.2.3, we write $\exists x\, \varphi$ for $\neg\forall x\, \neg\varphi$ and $t \neq s$ for $\neg(t = s)$.

Example 2.3.5.

1. The language of groups has a constant symbol e, a unary function symbol $^{-1}$ and a binary function symbol $\cdot$.
2. The language of rings has constant symbols $0, 1$ and binary function symbols $+, \cdot$ and a unary function symbol $-$.
3. The language of orders has a single binary relation symbol $<$.
4. The language of set theory has a single binary relation symbol $\in$.
5. The language of arithmetic $\mathcal{L}_A$ has a constant symbol 0, a unary function symbol S and binary function symbols $+$ and $\cdot$.

All these languages are countable.

Definition 2.3.6. The set $\mathrm{Var}(t)$ of variables of a term t is defined as usual. The set $\mathrm{FV}(\varphi)$ of *free variables* of a formula is defined by recursion: $\mathrm{FV}(t_1 = t_2) = \mathrm{Var}(t_1) \cup \mathrm{Var}(t_2)$, $\mathrm{FV}(R(t_1, \dots, t_n)) = \bigcup_i \mathrm{Var}(t_i)$, $\mathrm{FV}(\neg\varphi) = \mathrm{FV}(\varphi)$, $\mathrm{FV}(\varphi \to \psi) = \mathrm{FV}(\varphi) \cup \mathrm{FV}(\psi)$ and $\mathrm{FV}(\forall x\, \varphi) = \mathrm{FV}(\varphi) \setminus \{x\}$. A *sentence* is a formula without free variables. A variable *occurs* in φ if it appears anywhere in the tree φ, free or not.

Definition 2.3.7. Let x be a variable and t a term. For a term u, the term $u[t/x]$ is obtained by replacing every occurrence of x in u by t. For formulas, $\varphi[t/x]$ is defined by recursion: $(t_1 = t_2)[t/x] = (t_1[t/x] = t_2[t/x])$ and similarly for $R(t_1, \dots, t_n)$; $(\neg\varphi)[t/x] = \neg(\varphi[t/x])$; $(\varphi \to \psi)[t/x] = (\varphi[t/x] \to \psi[t/x])$; $(\forall y\, \varphi)[t/x] = \forall y\, \varphi$ if $y = x$, and $(\forall y\, \varphi)[t/x] = \forall y\, (\varphi[t/x])$ if $y \neq x$.

The term t is *substitutable* for x in φ if: φ is atomic; or $\varphi = \neg\psi$ and t is substitutable for x in ψ; or $\varphi = (\psi \to \chi)$ and t is substitutable for x in ψ and in χ; or $\varphi = \forall y\, \psi$ and either $x \notin \mathrm{FV}(\varphi)$, or y does not occur in t and t is substitutable for x in ψ.

Remark 2.3.8. Two facts follow at once by induction: if $x \notin \mathrm{FV}(\varphi)$ then $\varphi[t/x] = \varphi$; and substitution does not change the complexity, $c(\varphi[t/x]) = c(\varphi)$. A constant symbol, or more generally a term without variables, is substitutable for every variable in every formula.

Lemma 2.3.9. *Let x and y be variables, and suppose y does not occur in the formula φ. Then y is substitutable for x in φ, x is substitutable for y in $\varphi[y/x]$, and $\varphi[y/x][x/y] = \varphi$.*

Proof. For terms u not containing y, clearly $u[y/x][x/y] = u$. This gives the claims for atomic formulas, and the cases $\neg$ and $\rightarrow$ follow by induction. Let $\varphi = \forall z\, \psi$; then $z \neq y$ and y does not occur in ψ. The variable z does not occur in the term y, so by induction y is substitutable for x in φ. If $z = x$, then $\varphi[y/x] = \varphi$, in which y is not free, so x is substitutable for y in it and $\varphi[x/y] = \varphi$. If $z \neq x$, then $\varphi[y/x] = \forall z\, \psi[y/x]$; since z does not occur in the term x, the induction hypothesis shows that x is substitutable for y in $\varphi[y/x]$, and $\varphi[y/x][x/y] = \forall z\, \psi[y/x][x/y] = \forall z\, \psi$. □

2.4 Structures and satisfaction

Definition 2.4.1. A *structure* $\mathcal{A}$ for a language $\mathcal{L}$ consists of a nonempty set A, its *universe*, together with an element $c^{\mathcal{A}} \in A$ for every constant symbol c, a map $f^{\mathcal{A}} \colon A^n \to A$ for every n-ary function symbol f, and a subset $R^{\mathcal{A}} \subseteq A^n$ for every n-ary relation symbol R. An *assignment* in $\mathcal{A}$ is a map s from the set of variables to A. For an assignment s, a variable x and $a \in A$, we write $s[x \mapsto a]$ for the assignment that agrees with s except that it sends x to a.

Definition 2.4.2. Let $\mathcal{A}$ be a structure and s an assignment. The *value* $t^{\mathcal{A}}[s] \in A$ of a term is defined by $x^{\mathcal{A}}[s] = s(x)$, $c^{\mathcal{A}}[s] = c^{\mathcal{A}}$ and $f(t_1, \ldots, t_n)^{\mathcal{A}}[s] = f^{\mathcal{A}}(t_1^{\mathcal{A}}[s], \ldots, t_n^{\mathcal{A}}[s])$. The relation $\mathcal{A} \models \varphi[s]$, read "$\mathcal{A}$ satisfies φ under s", is defined by recursion on φ:

1. $\mathcal{A} \models (t_1 = t_2)[s]$ if and only if $t_1^{\mathcal{A}}[s] = t_2^{\mathcal{A}}[s]$;
2. $\mathcal{A} \models R(t_1, \ldots, t_n)[s]$ if and only if $(t_1^{\mathcal{A}}[s], \ldots, t_n^{\mathcal{A}}[s]) \in R^{\mathcal{A}}$;
3. $\mathcal{A} \models \neg\varphi[s]$ if and only if $\mathcal{A} \not\models \varphi[s]$;
4. $\mathcal{A} \models (\varphi \rightarrow \psi)[s]$ if and only if $\mathcal{A} \not\models \varphi[s]$ or $\mathcal{A} \models \psi[s]$;
5. $\mathcal{A} \models \forall x\, \varphi[s]$ if and only if $\mathcal{A} \models \varphi[s[x \mapsto a]]$ for every $a \in A$.

Remark 2.4.3. With the abbreviations of Notation 2.3.4, $\mathcal{A} \models \exists x\, \varphi[s]$ if and only if $\mathcal{A} \models \varphi[s[x \mapsto a]]$ for some $a \in A$, and the connectives $\wedge$, $\vee$, $\leftrightarrow$ have their usual meaning, by the same computation as in Lemma 2.2.8.

Lemma 2.4.4 (Coincidence lemma)**.** *Let s and s' be assignments in $\mathcal{A}$. If they agree on* $\mathrm{Var}(t)$*, then $t^{\mathcal{A}}[s] = t^{\mathcal{A}}[s']$. If they agree on* $\mathrm{FV}(\varphi)$*, then $\mathcal{A} \models \varphi[s]$ if and only if $\mathcal{A} \models \varphi[s']$.*

Proof. The statement for terms follows by induction on terms, and implies the statement for atomic formulas; the cases $\neg$ and $\rightarrow$ follow by induction. If $\varphi = \forall x\, \psi$ and s, s' agree on $\mathrm{FV}(\varphi) = \mathrm{FV}(\psi) \setminus \{x\}$, then for each $a \in A$ the assignments $s[x \mapsto a]$ and $s'[x \mapsto a]$ agree on $\mathrm{FV}(\psi)$, and the claim follows from the induction hypothesis. □

Notation 2.4.5. By Lemma 2.4.4, whether $\mathcal{A} \models \sigma[s]$ holds for a sentence σ does not depend on s; we then write $\mathcal{A} \models \sigma$ and say that σ is *true* in $\mathcal{A}$.

Lemma 2.4.6 (Substitution lemma)**.** *Let t be substitutable for x in φ, let s be an assignment in $\mathcal{A}$, and put $a = t^{\mathcal{A}}[s]$. Then $\mathcal{A} \models \varphi[t/x][s]$ if and only if $\mathcal{A} \models \varphi[s[x \mapsto a]]$. Also $u[t/x]^{\mathcal{A}}[s] = u^{\mathcal{A}}[s[x \mapsto a]]$ for every term u.*

Proof. The statement for terms follows by induction on u and gives the atomic case; the cases $\neg$ and $\to$ follow by induction. Let $\varphi = \forall y\, \psi$.

If $x \notin \mathrm{FV}(\varphi)$, then $\varphi[t/x] = \varphi$ (Remark 2.3.8), and s and $s[x \mapsto a]$ agree on $\mathrm{FV}(\varphi)$, so the claim follows from Lemma 2.4.4.

Otherwise $y \neq x$, y does not occur in t, and t is substitutable for x in ψ. Then $\varphi[t/x] = \forall y\, \psi[t/x]$. For $b \in A$, since y does not occur in t, we have $t^{\mathcal{A}}[s[y \mapsto b]] = a$, so by induction $\mathcal{A} \models \psi[t/x][s[y \mapsto b]]$ if and only if $\mathcal{A} \models \psi[s[y \mapsto b][x \mapsto a]]$. Since $x \neq y$, the assignment $s[y \mapsto b][x \mapsto a]$ equals $s[x \mapsto a][y \mapsto b]$. Quantifying over all $b \in A$ gives the claim. □

Counterexample 2.4.7. The hypothesis that t is substitutable cannot be dropped. Let φ be $\exists y\, (x \neq y)$ and $t = y$. In a structure with at least two elements, φ is true under every assignment, but $\varphi[y/x] = \exists y\, (y \neq y)$ is false: the variable y of t has been "captured" by the quantifier $\exists y$.

Definition 2.4.8. Let Γ be a set of formulas. A structure $\mathcal{A}$ with an assignment s *satisfies* Γ if $\mathcal{A} \models \gamma[s]$ for all $\gamma \in \Gamma$. The set Γ *logically implies* φ, written $\Gamma \models \varphi$, if every $(\mathcal{A}, s)$ satisfying Γ satisfies φ; φ is *valid* if $\emptyset \models \varphi$. A *theory* is a set of sentences. A *model* of a theory T is a structure in which all sentences of T are true. For a structure $\mathcal{A}$, the *theory of* $\mathcal{A}$, written $\mathrm{Th}(\mathcal{A})$, is the set of sentences true in $\mathcal{A}$.

Example 2.4.9. Let T_{grp} consist of the sentences $\forall x \forall y \forall z\, ((x \cdot y) \cdot z = x \cdot (y \cdot z))$, $\forall x\, (x \cdot e = x \wedge e \cdot x = x)$ and $\forall x\, (x \cdot x^{-1} = e \wedge x^{-1} \cdot x = e)$ in the language of groups. Its models are exactly the groups (with the inverse map and the identity element as interpretations of $^{-1}$ and e). Adding $\forall x \forall y\, (x \cdot y = y \cdot x)$ gives a theory whose models are the abelian groups.

Definition 2.4.10. An *isomorphism* of $\mathcal{L}$-structures $h \colon \mathcal{A} \to \mathcal{B}$ is a bijection $h \colon A \to B$ with $h(c^{\mathcal{A}}) = c^{\mathcal{B}}$, $h(f^{\mathcal{A}}(a_1, \ldots, a_n)) = f^{\mathcal{B}}(h(a_1), \ldots, h(a_n))$ and $(a_1, \ldots, a_n) \in R^{\mathcal{A}}$ if and only if $(h(a_1), \ldots, h(a_n)) \in R^{\mathcal{B}}$, for all symbols and all $a_i \in A$.

Proposition 2.4.11. *Let $h \colon \mathcal{A} \to \mathcal{B}$ be an isomorphism and s an assignment in $\mathcal{A}$. Then $\mathcal{A} \models \varphi[s]$ if and only if $\mathcal{B} \models \varphi[h \circ s]$. In particular, isomorphic structures have the same theory.*

Proof. By induction on terms, $h(t^{\mathcal{A}}[s]) = t^{\mathcal{B}}[h \circ s]$. Since h is injective and preserves relations in both directions, the atomic case follows; the cases $\neg$, $\to$ follow by induction. For $\forall x\, \psi$, note that $h \circ (s[x \mapsto a]) = (h \circ s)[x \mapsto h(a)]$ and that $a \mapsto h(a)$ is a bijection $A \to B$, so quantifying over $a \in A$ is the same as quantifying over $b \in B$. □

2.5 Formal deductions

We now define formal proofs. The system below, a Hilbert-style system with modus ponens as its only rule, is the one of [End01].

Definition 2.5.1. A formula is *prime* if it is atomic or of the form $\forall x\, \varphi$. Every formula is built from prime formulas using $\neg$ and $\to$ alone. A *truth assignment* for $\mathcal{L}$ is a map v from the set of prime formulas to $\{0, 1\}$; it extends to $\bar{v}$ on all formulas as in Definition 2.2.6. A formula is a *tautology* if $\bar{v}(\varphi) = 1$ for all v, and a set Σ *tautologically implies* φ if $\bar{v}(\varphi) = 1$ for all v with $\bar{v}(\Sigma) = \{1\}$.

Definition 2.5.2. A *generalization* of a formula α is a formula $\forall x_1 \cdots \forall x_n\, \alpha$ with $n \geq 0$. The *logical axioms* are all generalizations of formulas of the following forms, where x, y, z are variables, t is a term and α, β are formulas:

(A1) tautologies;

(A2) $\forall x\, \alpha \to \alpha[t/x]$, where t is substitutable for x in α;

(A3) $\forall x\, (\alpha \to \beta) \to (\forall x\, \alpha \to \forall x\, \beta)$;

(A4) $\alpha \to \forall x\, \alpha$, where $x \notin \mathrm{FV}(\alpha)$;

(A5) $x = x$;

(A6) $x = y \to (\alpha[x/z] \to \alpha[y/z])$, where α is atomic.

Definition 2.5.3. Let Γ be a set of formulas. A *deduction* from Γ is a finite sequence $(\alpha_0, \dots, \alpha_n)$ of formulas such that each α_i is a logical axiom, or belongs to Γ, or is obtained by *modus ponens* from earlier formulas, that is, there are $j, k < i$ with $\alpha_k = (\alpha_j \to \alpha_i)$. We write $\Gamma \vdash \varphi$, and say that φ is a *theorem* of Γ, if there is a deduction from Γ whose last formula is φ. The set Γ is *inconsistent* if there is a formula β with $\Gamma \vdash \beta$ and $\Gamma \vdash \neg\beta$, and *consistent* otherwise.

Remark 2.5.4. A deduction is finite, so it uses only finitely many formulas of Γ. Hence $\Gamma \vdash \varphi$ if and only if $\Gamma_0 \vdash \varphi$ for some finite $\Gamma_0 \subseteq \Gamma$, and Γ is consistent if and only if all its finite subsets are. Whether $\Gamma \vdash \varphi$ holds could depend on the language in which deductions are carried out; see Lemma 2.5.12 below.

Lemma 2.5.5 (Rule T)**.** *If $\Gamma \vdash \alpha_1, \dots, \Gamma \vdash \alpha_n$ and $\{\alpha_1, \dots, \alpha_n\}$ tautologically implies β, then $\Gamma \vdash \beta$. In particular, if Γ is inconsistent, then $\Gamma \vdash \beta$ for every formula β.*

Proof. The formula $\alpha_1 \to (\alpha_2 \to \cdots(\alpha_n \to \beta)\cdots)$ is a tautology, hence a logical axiom. Applying modus ponens n times gives $\Gamma \vdash \beta$. For the second claim, $\{\gamma, \neg\gamma\}$ tautologically implies every formula. □

Theorem 2.5.6 (Soundness)**.** *If $\Gamma \vdash \varphi$, then $\Gamma \models \varphi$. In particular, a set of formulas that is satisfied by some structure and assignment is consistent.*

Proof. We first show that every logical axiom is valid. If α is valid, so is every generalization of α, by the definition of satisfaction. Fix $\mathcal{A}$ and s. (A1) Let $v(\pi) = 1$ if and only if $\mathcal{A} \models \pi[s]$, for prime π. By induction, $\bar{v}(\alpha) = 1$ if and only if $\mathcal{A} \models \alpha[s]$; so tautologies are satisfied. (A2) If $\mathcal{A} \models \forall x\, \alpha[s]$ then $\mathcal{A} \models \alpha[s[x \mapsto t^{\mathcal{A}}[s]]]$, which by Lemma 2.4.6 means $\mathcal{A} \models \alpha[t/x][s]$. (A3) is immediate from the definitions. (A4) If $x \notin \mathrm{FV}(\alpha)$, then s and $s[x \mapsto a]$ agree on $\mathrm{FV}(\alpha)$, so this follows from Lemma 2.4.4. (A5) is clear. (A6) If $s(x) = s(y) = a$, then by Lemma 2.4.6 both $\alpha[x/z]$ and $\alpha[y/z]$ are satisfied under s if and only if α is satisfied under $s[z \mapsto a]$.

Now let $(\alpha_0, \dots, \alpha_n)$ be a deduction from Γ and let $(\mathcal{A}, s)$ satisfy Γ. By induction on i, $\mathcal{A} \models \alpha_i[s]$: this holds for axioms and elements of Γ, and if $\mathcal{A} \models \alpha_j[s]$ and $\mathcal{A} \models (\alpha_j \to \alpha_i)[s]$ then $\mathcal{A} \models \alpha_i[s]$. For the last claim, no $(\mathcal{A}, s)$ satisfies both β and $\neg\beta$. □

Theorem 2.5.7 (Generalization theorem)**.** *If $\Gamma \vdash \varphi$ and x is not free in any formula of Γ, then $\Gamma \vdash \forall x\, \varphi$.*

Proof. We show by induction on i that $\Gamma \vdash \forall x\, \alpha_i$ for every formula α_i of a deduction $(\alpha_0, \dots, \alpha_n)$ from Γ. If α_i is a logical axiom, so is its generalization $\forall x\, \alpha_i$. If $\alpha_i \in \Gamma$, then $x \notin \mathrm{FV}(\alpha_i)$, so $\alpha_i \to \forall x\, \alpha_i$ is an instance of (A4), and modus ponens gives $\Gamma \vdash \forall x\, \alpha_i$. If α_i is obtained from α_j and $\alpha_j \to \alpha_i$ by modus ponens, then by induction $\Gamma \vdash \forall x\, \alpha_j$ and $\Gamma \vdash \forall x\, (\alpha_j \to \alpha_i)$; using the instance $\forall x\, (\alpha_j \to \alpha_i) \to (\forall x\, \alpha_j \to \forall x\, \alpha_i)$ of (A3) and modus ponens twice, $\Gamma \vdash \forall x\, \alpha_i$. □

Theorem 2.5.8 (Deduction theorem)**.** $\Gamma \cup \{\gamma\} \vdash \varphi$ *if and only if* $\Gamma \vdash \gamma \to \varphi$.

Proof. If $\Gamma \vdash \gamma \to \varphi$, then $\Gamma \cup \{\gamma\}$ proves both $\gamma \to \varphi$ and γ, hence φ. Conversely, let $(\alpha_0, \ldots, \alpha_n)$ be a deduction from $\Gamma \cup \{\gamma\}$; we show $\Gamma \vdash \gamma \to \alpha_i$ by induction on i. If $\alpha_i = \gamma$, then $\gamma \to \gamma$ is a tautology. If α_i is a logical axiom or lies in Γ, then $\Gamma \vdash \alpha_i$, and α_i tautologically implies $\gamma \to \alpha_i$; apply Lemma 2.5.5. If α_i comes from α_j and $\alpha_j \to \alpha_i$ by modus ponens, then by induction Γ proves $\gamma \to \alpha_j$ and $\gamma \to (\alpha_j \to \alpha_i)$, and these two formulas tautologically imply $\gamma \to \alpha_i$. □

Corollary 2.5.9 (Reductio ad absurdum)**.** *If $\Gamma \cup \{\neg\varphi\}$ is inconsistent, then $\Gamma \vdash \varphi$. If $\Gamma \cup \{\varphi\}$ is inconsistent, then $\Gamma \vdash \neg\varphi$.*

Proof. If $\Gamma \cup \{\neg\varphi\}$ proves β and $\neg\beta$, then by Theorem 2.5.8 Γ proves $\neg\varphi \to \beta$ and $\neg\varphi \to \neg\beta$, which tautologically imply φ. The second statement is proved in the same way, using that $\{\varphi \to \beta, \varphi \to \neg\beta\}$ tautologically implies $\neg\varphi$. □

For a constant symbol c and a variable y, let $\alpha[y/c]$ denote the result of replacing every occurrence of c in α by y (defined by recursion like substitution, but also inside the scope of quantifiers).

Lemma 2.5.10. *Let $(\alpha_0, \ldots, \alpha_n)$ be a deduction from Γ, let c be a constant symbol that does not occur in any formula of Γ, and let y be a variable that does not occur in any α_i. Then $(\alpha_0[y/c], \ldots, \alpha_n[y/c])$ is a deduction from Γ.*

Proof. Elements of Γ are unchanged, and replacement commutes with $\to$, so applications of modus ponens remain applications of modus ponens. It remains to see that the replacement of a logical axiom α is a logical axiom. Replacement commutes with generalization, so we may assume α is of one of the forms (A1)–(A6). Note that y does not occur in α.

(A1) Let w be a truth assignment, and define $v(\pi) = w(\pi[y/c])$ for prime π; replacement sends prime formulas to prime formulas and commutes with $\neg$ and $\to$, so $\bar{v}(\alpha) = \bar{w}(\alpha[y/c])$. Hence if α is a tautology so is $\alpha[y/c]$. (A2) By induction on formulas, $\beta[t/x][y/c] = \beta[y/c][t[y/c]/x]$. The term $t[y/c]$ is substitutable for x in $\beta[y/c]$: the only variable it may contain besides those of t is y, and y is not quantified anywhere in β. (A3), (A5) are clear, and (A4) is preserved because the variable x occurs in α, so $x \neq y$, and replacing a constant by y does not make x free. (A6) Write the axiom as $x = x' \to (\beta[x/z] \to \beta[x'/z])$ with β atomic; renaming z if necessary we may assume $z \neq y$. Then its replacement is $x = x' \to (\beta[y/c][x/z] \to \beta[y/c][x'/z])$, again an instance of (A6). □

Corollary 2.5.11 (Generalization on constants)**.** *Suppose $\Gamma \vdash \varphi[c/x]$, where the constant symbol c occurs neither in Γ nor in φ. Then $\Gamma \vdash \forall x\, \varphi$.*

Proof. Choose a deduction of $\varphi[c/x]$ from Γ, and a variable $y \neq x$ that occurs neither in this deduction nor in φ. Since c does not occur in φ, we have $\varphi[c/x][y/c] = \varphi[y/x]$. By Lemma 2.5.10, there is a deduction of $\varphi[y/x]$ from a finite subset $\Gamma_0 \subseteq \Gamma$ in whose formulas y does not occur. By Theorem 2.5.7, $\Gamma_0 \vdash \forall y\, \varphi[y/x]$.

By Lemma 2.3.9, x is substitutable for y in $\varphi[y/x]$ and $\varphi[y/x][x/y] = \varphi$, so $\forall y\, \varphi[y/x] \to \varphi$ is an instance of (A2). Hence $\{\forall y\, \varphi[y/x]\} \vdash \varphi$. The variable x is not free in $\forall y\, \varphi[y/x]$, so Theorem 2.5.7 and Theorem 2.5.8 give $\vdash \forall y\, \varphi[y/x] \to \forall x\, \varphi$. By modus ponens, $\Gamma \vdash \forall x\, \varphi$. □

Lemma 2.5.12. *Let $\mathcal{L}'$ be obtained from $\mathcal{L}$ by adding new constant symbols. If $\Gamma \cup \{\varphi\}$ is a set of $\mathcal{L}$-formulas and $\Gamma \vdash \varphi$ by a deduction in $\mathcal{L}'$, then $\Gamma \vdash \varphi$ by a deduction in $\mathcal{L}$. In particular, a set of $\mathcal{L}$-formulas that is consistent in $\mathcal{L}$ is consistent in $\mathcal{L}'$.*

Proof. A deduction in $\mathcal{L}'$ contains finitely many new constants. Replace them one at a time by distinct variables not occurring in the deduction. By Lemma 2.5.10 (applied in $\mathcal{L}'$), the result is a deduction from Γ of φ, which is unchanged because it contains no new constants.

All its formulas are $\mathcal{L}$-formulas, and an $\mathcal{L}$-formula that is a logical axiom of $\mathcal{L}'$ is a logical axiom of $\mathcal{L}$ (for (A1), every prime $\mathcal{L}$-formula is a prime $\mathcal{L}'$-formula). The last statement follows by applying the first to $\varphi = (x = x)$ and $\varphi = \neg(x = x)$, using Lemma 2.5.5. □

Lemma 2.5.13 (Equality)**.** *For all terms $t, t', t'', t_1, \dots, t_n, s_1, \dots, s_n$:*

1. $\vdash t = t$;
2. $\{t = t'\} \vdash t' = t$;
3. $\{t = t', t' = t''\} \vdash t = t''$;
4. $\{t_1 = s_1, \dots, t_n = s_n\} \vdash f(t_1, \dots, t_n) = f(s_1, \dots, s_n)$ *for every n-ary function symbol f;*
5. $\{t_1 = s_1, \dots, t_n = s_n, R(t_1, \dots, t_n)\} \vdash R(s_1, \dots, s_n)$ *for every n-ary relation symbol R.*

Proof. We use the following observation. If $\vdash \beta$ where β has no quantifiers, and $x_1, \dots, x_k$ are distinct variables not occurring in the terms $u_1, \dots, u_k$, then $\vdash \beta[u_1/x_1] \cdots [u_k/x_k]$. Indeed, by Theorem 2.5.7, $\vdash \forall x_1 \cdots \forall x_k \, \beta$, and we remove the quantifiers one at a time with (A2): each term u_i is substitutable because it contains none of the quantified variables and the remaining formula has no other quantifiers. In each part below, the variables used are chosen distinct and not occurring in the terms of the statement.

(1) Apply the observation to the axiom $x = x$. (2) Let α be $z = x$. The instance $x = y \to (x = x \to y = x)$ of (A6), with $x := t$ and $y := t'$, together with (1) gives the claim. (3) Let α be $z = w$. The instance $x = y \to (x = w \to y = w)$ of (A6), with $x := t'$, $y := t$, $w := t''$, gives $\vdash t' = t \to (t' = t'' \to t = t'')$; combine with (2). (4) For $0 \le k \le n$ let $a_k = f(y_1, \dots, y_k, x_{k+1}, \dots, x_n)$. With α the atomic formula $f(x_1, \dots, x_n) = f(y_1, \dots, y_{k-1}, z, x_{k+1}, \dots, x_n)$, axiom (A6) gives $\vdash x_k = y_k \to (f(x_1, \dots, x_n) = a_{k-1} \to f(x_1, \dots, x_n) = a_k)$. Starting from $f(x_1, \dots, x_n) = a_0$, which holds by (1), we obtain $\{x_1 = y_1, \dots, x_n = y_n\} \vdash f(x_1, \dots, x_n) = a_n$. By the deduction theorem this becomes a deducible quantifier-free implication, and the observation with $x_i := t_i$, $y_i := s_i$ gives the claim. (5) is proved in the same way as (4), with α the atomic formula $R(y_1, \dots, y_{k-1}, z, x_{k+1}, \dots, x_n)$. □

Lemma 2.5.14 (Alphabetic variants)**.** *Let φ be a formula, x a variable and t a term. There is a formula φ' with $c(\varphi') = c(\varphi)$ such that t is substitutable for x in φ', $\vdash \varphi \to \varphi'$ and $\vdash \varphi' \to \varphi$.*

Proof. By induction on φ. For atomic φ take $\varphi' = \varphi$. For $\neg\psi$ and $\psi \to \chi$, take $\neg\psi'$ and $\psi' \to \chi'$ and use Lemma 2.5.5. Let $\varphi = \forall y \, \psi$, and let ψ' be given by induction. Choose a variable z that does not occur in ψ' or in t and is different from x, and put $\varphi' = \forall z \, \psi'[z/y]$.

The term t is substitutable for x in φ'. If $x = y$, then x is not free in φ'. If $x \neq y$, then z does not occur in t, and t is substitutable for x in $\psi'[z/y]$ because it is substitutable in ψ' and $\psi'[z/y]$ has the same quantifiers as ψ' in the same places.

From $\vdash \psi \to \psi'$, Theorem 2.5.7 and (A3) give $\vdash \forall y \, \psi \to \forall y \, \psi'$, and similarly $\vdash \forall y \, \psi' \to \forall y \, \psi$. By Lemma 2.3.9, $\forall y \, \psi' \to \psi'[z/y]$ and $\forall z \, \psi'[z/y] \to \psi'$ are instances of (A2). The variable z is not free in $\forall y \, \psi'$, and y is not free in $\forall z \, \psi'[z/y]$; so by Theorems 2.5.7 and 2.5.8, $\vdash \forall y \, \psi' \to \forall z \, \psi'[z/y]$ and $\vdash \forall z \, \psi'[z/y] \to \forall y \, \psi'$. Combining these implications with Lemma 2.5.5 gives the claim. Finally $c(\varphi') = c(\psi') + 1 = c(\varphi)$. □

Example 2.5.15. Let us check that $\vdash \forall x \forall y \, \varphi \to \forall y \forall x \, \varphi$. By (A2) twice (a variable is substitutable for itself), $\{\forall x \forall y \, \varphi\} \vdash \varphi$. Neither x nor y is free in $\forall x \forall y \, \varphi$, so the generalization theorem gives $\{\forall x \forall y \, \varphi\} \vdash \forall y \forall x \, \varphi$, and the deduction theorem gives the claim. In practice, one rarely writes deductions: by Corollary 2.6.2 below it suffices to check that the implication is valid.

2.6 The completeness theorem

Theorem 2.6.1 (Gödel, Henkin)**.** *Let $\mathcal{L}$ be a countable language and Γ a consistent set of $\mathcal{L}$-formulas. Then there are an $\mathcal{L}$-structure $\mathcal{A}$ with a countable universe and an assignment s such that $(\mathcal{A}, s)$ satisfies Γ.*

Proof. This is the method of [Hen49]; the theorem is due to [Gö30].

Step 1: new constants. Let $\mathcal{L}'$ be $\mathcal{L}$ together with new constant symbols $c_0, c_1, \ldots$. It is still countable, and Γ is consistent in $\mathcal{L}'$ by Lemma 2.5.12. From now on all formulas and deductions are in $\mathcal{L}'$.

Step 2: witnesses. Enumerate all pairs of a formula and a variable as $(\varphi_1, x_1), (\varphi_2, x_2), \ldots$. Define inductively

$$\theta_n = \big(\neg\forall x_n\, \varphi_n \to \neg\varphi_n[d_n/x_n]\big),$$

where d_n is the first of the new constants c_i that occurs neither in φ_n nor in $\theta_1, \ldots, \theta_{n-1}$. Let $\Theta = \{\theta_1, \theta_2, \ldots\}$. We claim that $\Gamma \cup \Theta$ is consistent. Otherwise, by Remark 2.5.4, there is a least m such that $\Gamma \cup \{\theta_1, \ldots, \theta_m\}$ is inconsistent, and $m \geq 1$. By Corollary 2.5.9, $\Gamma \cup \{\theta_1, \ldots, \theta_{m-1}\} \vdash \neg\theta_m$. The formula $\neg\theta_m$ tautologically implies both $\neg\forall x_m\, \varphi_m$ and $\varphi_m[d_m/x_m]$. The constant d_m occurs neither in Γ (whose formulas are in $\mathcal{L}$), nor in $\theta_1, \ldots, \theta_{m-1}$, nor in φ_m; so Corollary 2.5.11 gives $\Gamma \cup \{\theta_1, \ldots, \theta_{m-1}\} \vdash \forall x_m\, \varphi_m$. This set is therefore inconsistent, contradicting the minimality of m.

Step 3: a maximal consistent set. Enumerate all formulas as $\psi_0, \psi_1, \ldots$. Put $\Delta_0 = \Gamma \cup \Theta$, and $\Delta_{n+1} = \Delta_n \cup \{\psi_n\}$ if this set is consistent, $\Delta_{n+1} = \Delta_n \cup \{\neg\psi_n\}$ otherwise. If Δ_n is consistent, so is Δ_{n+1}: if both $\Delta_n \cup \{\psi_n\}$ and $\Delta_n \cup \{\neg\psi_n\}$ were inconsistent, then Δ_n would prove $\neg\psi_n$ and ψ_n by Corollary 2.5.9. Let $\Delta = \bigcup_n \Delta_n$. It is consistent (a deduction uses finitely many formulas), and for every formula ψ either $\psi \in \Delta$ or $\neg\psi \in \Delta$, but not both. Moreover, if $\Delta \vdash \psi$ then $\psi \in \Delta$: otherwise $\neg\psi \in \Delta$ and Δ would be inconsistent.

Step 4: the term structure. Let T be the set of terms of $\mathcal{L}'$; it is countable. For $t, t' \in T$ write $t \sim t'$ if $(t = t') \in \Delta$. Since Δ contains every formula it proves, Lemma 2.5.13 shows that $\sim$ is an equivalence relation and that

- if $t_i \sim s_i$ for all i, then $f(t_1, \ldots, t_n) \sim f(s_1, \ldots, s_n)$, and $R(t_1, \ldots, t_n) \in \Delta$ if and only if $R(s_1, \ldots, s_n) \in \Delta$.

Let $A = T/\!\sim$ and write $[t]$ for the class of t. Define an $\mathcal{L}'$-structure $\mathcal{A}$ with universe A by $c^{\mathcal{A}} = [c]$, $f^{\mathcal{A}}([t_1], \ldots, [t_n]) = [f(t_1, \ldots, t_n)]$ and $([t_1], \ldots, [t_n]) \in R^{\mathcal{A}}$ if and only if $R(t_1, \ldots, t_n) \in \Delta$; these are well defined by the displayed property. Let $s(x) = [x]$. By induction on terms, $t^{\mathcal{A}}[s] = [t]$ for every term t.

Step 5: the truth lemma. We show that for every formula φ,

$$\mathcal{A} \models \varphi[s] \iff \varphi \in \Delta,$$

by induction on the complexity $c(\varphi)$. For $t_1 = t_2$ both sides say $[t_1] = [t_2]$; for $R(t_1, \ldots, t_n)$ both sides say $R(t_1, \ldots, t_n) \in \Delta$. For $\neg\psi$: $\mathcal{A} \models \neg\psi[s]$ iff $\psi \notin \Delta$ iff $\neg\psi \in \Delta$. For $\psi \to \chi$: if $(\psi \to \chi) \in \Delta$ and $\psi \in \Delta$, then $\Delta \vdash \chi$, so $\chi \in \Delta$; conversely, if $\psi \notin \Delta$ then $\neg\psi \in \Delta$, and if $\chi \in \Delta$, in either case Δ proves $\psi \to \chi$ by Lemma 2.5.5. Hence $(\psi \to \chi) \in \Delta$ iff $\psi \notin \Delta$ or $\chi \in \Delta$, iff $\mathcal{A} \models (\psi \to \chi)[s]$.

Let $\varphi = \forall x\, \psi$. Suppose $\varphi \notin \Delta$. The pair (ψ, x) is (φ_n, x_n) for some n, and $\neg\forall x\, \psi \in \Delta$ and $\theta_n \in \Delta$, so $\neg\psi[d_n/x] \in \Delta$ and $\psi[d_n/x] \notin \Delta$. Since $c(\psi[d_n/x]) = c(\psi) < c(\varphi)$, the induction hypothesis gives $\mathcal{A} \not\models \psi[d_n/x][s]$, which by Lemma 2.4.6 means $\mathcal{A} \not\models \psi[s[x \mapsto [d_n]]]$. Hence $\mathcal{A} \not\models \varphi[s]$.

Suppose $\varphi \in \Delta$, and let $a \in A$, say $a = [t]$. Let ψ' be as in Lemma 2.5.14 for ψ, x and t. From $\vdash \psi \to \psi'$ we get $\vdash \forall x\, \psi \to \forall x\, \psi'$ (generalization and (A3)), so $\forall x\, \psi' \in \Delta$,

and by (A2) $\psi'[t/x] \in \Delta$. Since $c(\psi'[t/x]) = c(\psi) < c(\varphi)$, the induction hypothesis gives $\mathcal{A} \models \psi'[t/x][s]$, that is, $\mathcal{A} \models \psi'[s[x \mapsto a]]$ by Lemma 2.4.6. As $\vdash \psi' \to \psi$, Theorem 2.5.6 gives $\mathcal{A} \models \psi[s[x \mapsto a]]$. Since a was arbitrary, $\mathcal{A} \models \varphi[s]$.

Step 6: conclusion. Since $\Gamma \subseteq \Delta$, the pair $(\mathcal{A}, s)$ satisfies Γ. Forgetting the interpretations of the new constants gives an $\mathcal{L}$-structure which, with the same assignment, still satisfies Γ, because the satisfaction of an $\mathcal{L}$-formula only involves the symbols of $\mathcal{L}$. Its universe A is countable, as a quotient of T. □

Corollary 2.6.2 (Completeness theorem)**.** *Let $\mathcal{L}$ be countable. Then $\Gamma \models \varphi$ if and only if $\Gamma \vdash \varphi$.*

Proof. One direction is Theorem 2.5.6. Suppose $\Gamma \nvdash \varphi$. By Corollary 2.5.9, $\Gamma \cup \{\neg\varphi\}$ is consistent, so by Theorem 2.6.1 it is satisfied by some $(\mathcal{A}, s)$. Then $(\mathcal{A}, s)$ satisfies Γ but not φ, so $\Gamma \not\models \varphi$. □

Remark 2.6.3. The completeness theorem holds for languages of any cardinality, and the structure can then be taken of cardinality at most that of the language plus $\aleph_0$. The proof is the same, except that the enumerations of Steps 2 and 3 are replaced by transfinite ones, which requires the well-ordering theorem (Chapter 3); see [CK90, Section 2.2].

2.7 Compactness and the Löwenheim–Skolem theorem

Theorem 2.7.1 (Compactness theorem)**.** *Let $\mathcal{L}$ be countable and Γ a set of formulas. If every finite subset of Γ is satisfiable, then Γ is satisfiable.*

Proof. If Γ is not satisfiable, it is inconsistent by Theorem 2.6.1, so some finite subset Γ_0 is inconsistent (Remark 2.5.4), and Γ_0 is not satisfiable by Theorem 2.5.6. □

Theorem 2.7.2 (Löwenheim–Skolem)**.** *Let $\mathcal{L}$ be countable. Every satisfiable set of $\mathcal{L}$-formulas is satisfied by a structure with a countable (finite or countably infinite) universe. In particular, a theory with a model has a countable model.*

Proof. A satisfiable set is consistent by Theorem 2.5.6, and Theorem 2.6.1 produces a countable structure. □

Proposition 2.7.3. *Let $\mathcal{L}$ be countable and T a theory that has finite models of arbitrarily large size. Then T has an infinite model.*

Proof. For $n \geq 2$ let λ_n be the sentence $\exists x_1 \cdots \exists x_n \bigwedge_{1 \leq i < j \leq n} x_i \neq x_j$, which is true in a structure if and only if it has at least n elements. Every finite subset of $T \cup \{\lambda_n : n \geq 2\}$ is contained in $T \cup \{\lambda_2, \ldots, \lambda_N\}$ for some N, which is satisfied by a finite model of T with at least N elements. By Theorem 2.7.1, $T \cup \{\lambda_n : n \geq 2\}$ has a model, which is an infinite model of T. □

Counterexample 2.7.4. "Being finite" cannot be expressed in first-order logic: in any countable language there is no theory whose models are exactly the finite structures. Indeed, such a theory would have finite models of every size (in any language, every nonempty finite set carries a structure), hence an infinite model by Proposition 2.7.3.

Example 2.7.5. Let $\mathcal{N}$ be the structure $(\mathbb{N}, 0, S, +, \cdot)$ for the language of arithmetic, with $S(n) = n + 1$, and for $n \in \mathbb{N}$ let $\underline{n} = S(S(\cdots S(0)\cdots))$ with n symbols S. Add a new constant symbol c and consider $\mathrm{Th}(\mathcal{N}) \cup \{c \neq \underline{n} : n \in \mathbb{N}\}$. Every finite subset is satisfied by $\mathcal{N}$, interpreting c as a large enough number. By compactness there is a model $\mathcal{M}$ of $\mathrm{Th}(\mathcal{N})$ with an element $c^{\mathcal{M}}$ different from the values of all $\underline{n}$. Such a model is not isomorphic to $\mathcal{N}$ (in $\mathcal{N}$ every element is the value of some $\underline{n}$, and isomorphisms preserve the values of closed terms), although it satisfies exactly the same sentences. So first-order sentences cannot characterise $\mathcal{N}$ up to isomorphism.

Remark 2.7.6. Applied to set theory (Chapter 3), the Löwenheim–Skolem theorem says that if ZFC has a model, it has a countable model $\mathcal{M}$, even though ZFC proves that uncountable sets exist. There is no contradiction: an element of $\mathcal{M}$ that $\mathcal{M}$ believes to be uncountable has only countably many $\mathcal{M}$-elements, but no bijection with $\mathbb{N}$ exists *inside* $\mathcal{M}$. This is known as Skolem's paradox.

Remark 2.7.7. With the axiom of choice these results extend to languages and structures of any cardinality: Chapter 5 proves the compactness theorem for all languages, the downward and upward Löwenheim–Skolem theorems (a theory with an infinite model has models of every infinite cardinality at least that of the language), and Lindström's theorem, which characterises first-order logic by its compactness and Löwenheim–Skolem properties.

2.8 The incompleteness theorems

The completeness theorem says that the deductive calculus captures logical consequence: whatever is true in all models of a theory can be proved from it. The incompleteness theorems say something quite different, about *theories*: no reasonable theory of arithmetic decides every arithmetic sentence. The word "complete" is used in two senses here, and it is worth keeping them apart (Remark 2.8.5 below).

The incompleteness theorems are quoted without proof: their proofs require a precise theory of computability, which is not developed in this project. Complete proofs can be found in [Smi13] and [Sho67, Chapter 6]. We explain what they say, what they do not say, and why computability enters.

Definition 2.8.1. *Robinson arithmetic* Q is the theory in the language of arithmetic consisting of the sentences

$$\begin{aligned}
&\forall x\,(S(x) \neq 0), && \forall x \forall y\,(S(x) = S(y) \to x = y),\\
&\forall x\,(x \neq 0 \to \exists y\,(x = S(y))), && \forall x\,(x + 0 = x),\\
&\forall x \forall y\,(x + S(y) = S(x + y)), && \forall x\,(x \cdot 0 = 0),\\
&\forall x \forall y\,(x \cdot S(y) = x \cdot y + x).
\end{aligned}$$

Peano arithmetic PA consists of Q together with, for every formula φ whose free variables are among $x, y_1, \ldots, y_k$, the induction axiom $\forall y_1 \cdots \forall y_k \big((\varphi[0/x] \wedge \forall x\,(\varphi \to \varphi[S(x)/x])) \to \forall x\,\varphi\big)$.

Definition 2.8.2. A theory T is *complete* if for every sentence σ, either $T \vdash \sigma$ or $T \vdash \neg\sigma$. It is *computably axiomatized* if there is an algorithm deciding, for any sentence, whether it belongs to T.

Example 2.8.3. For every structure $\mathcal{A}$, the theory $\mathrm{Th}(\mathcal{A})$ is complete and consistent. For the structure $\mathcal{N}$ of Example 2.7.5, Theorem 2.8.7 implies that $\mathrm{Th}(\mathcal{N})$ is not computably axiomatized.

Example 2.8.4.

1. A finite theory, such as Q or the theory of groups, is computably axiomatized: to decide whether a sentence belongs to it, compare it with the finitely many axioms.

2. PA is infinite but computably axiomatized: a sentence belongs to PA if and only if it is one of the seven axioms of Q or has the shape of an induction axiom, and checking the shape is a mechanical inspection of the string of symbols.

3. The theory of algebraically closed fields of characteristic 0 (the field axioms, the sentences χ_p of Exercise 2.9.5, and for each $n \geq 1$ the sentence saying that every monic polynomial of degree n has a root) is computably axiomatized and infinite. It is also complete, by the Łoś–Vaught test (Chapter 5). This does not contradict the incompleteness theorem below, which concerns theories in the language of arithmetic that contain Q.

Remark 2.8.5. *Two meanings of "complete".* The *completeness theorem* (Corollary 2.6.2) is about the deductive calculus: $T \vdash \sigma$ if and only if σ is true in every model of T. A *complete theory* (Definition 2.8.2) is one that decides every sentence. The two notions are linked as follows: by the completeness theorem, a consistent theory T (in a countable language) fails to decide a sentence σ exactly when $T \nvdash \sigma$ and $T \nvdash \neg\sigma$, that is, when σ is true in some model of T and false in another. So T is complete if and only if all its models satisfy the same sentences.

Proposition 2.8.6. *Let $\mathcal{L}$ be countable and T a consistent theory. Then T is complete if and only if any two models of T satisfy the same sentences. If T is complete and computably axiomatized, then there is an algorithm deciding, for a sentence σ, whether $T \vdash \sigma$.*

Proof. If T is complete and $\mathcal{A}, \mathcal{B}$ are models, then for each sentence σ either $T \vdash \sigma$ or $T \vdash \neg\sigma$, and by soundness (Theorem 2.5.6) σ has the same truth value in $\mathcal{A}$ and $\mathcal{B}$. Conversely, if $T \nvdash \sigma$ and $T \nvdash \neg\sigma$, then by the completeness theorem $T \nvdash \sigma$ and $T \nvdash \neg\sigma$: there are a model in which σ is false and a model in which $\neg\sigma$ is false.

For the second statement, the deductions from T are finite strings of symbols, and whether a given string is a deduction from T can be checked mechanically, using an algorithm for membership in T to check the steps that cite axioms of T. So an algorithm can list all deductions from T, one after the other. Given σ, run through this list until a deduction of σ or of $\neg\sigma$ appears. As T is complete one of them appears after finitely many steps, and as T is consistent at most one of σ and $\neg\sigma$ is provable, so the answer is correct. □

The second half of this proposition shows where computability enters: a complete, computably axiomatized theory is decidable. So to prove that a theory is incomplete it suffices to prove that it is undecidable, and the first incompleteness theorem is, in essence, an undecidability theorem for arithmetic, proved by the diagonal argument of Remark 2.8.12 below.

Theorem 2.8.7 (First incompleteness theorem)**.** *Let T be a consistent, computably axiomatized theory in the language of arithmetic with $T \vdash \sigma$ for every $\sigma \in Q$. Then T is not complete.*

This is due to [Gö31], under a slightly stronger hypothesis than consistency, and in this form to [Ros36]; the theory Q is from [TMR53].

Remark 2.8.8. *What the first incompleteness theorem says, and what it does not say.*

1. It produces, for each such T, a sentence σ with $T \nvdash \sigma$ and $T \nvdash \neg\sigma$. By Proposition 2.8.6, T has a model in which σ is true and a model in which it is false. If $\mathcal{N}$ is a model of T, as for $T = \mathrm{PA}$, then one of $\sigma, \neg\sigma$ is true in $\mathcal{N}$ and not provable in T: there are true arithmetic statements that T does not prove, and the models in which they fail are nonstandard models, as in Example 2.7.5.

2. It does not say that some arithmetic truths are unprovable in an absolute sense: the unprovable sentence of T is provable in the larger theory $T \cup \{\sigma\}$. But this larger theory is again consistent and computably axiomatized, so it is incomplete in turn; no computably axiomatized extension of Q captures all of $\mathrm{Th}(\mathcal{N})$, which is Example 2.8.3.

3. The hypothesis "computably axiomatized" cannot be dropped: $\mathrm{Th}(\mathcal{N})$ itself is consistent, complete and contains Q. Nor can the hypothesis that T contains enough arithmetic: the theory of algebraically closed fields of characteristic 0 is complete (Example 2.8.4(3)).

4. The sentence σ produced by Gödel's proof says, via a coding of formulas and deductions by numbers, "I am not provable in T". Its truth in $\mathcal{N}$ is a consequence of the consistency of T, which leads to the second incompleteness theorem.

Theorem 2.8.9 (Second incompleteness theorem)**.** *Let T be a consistent, computably axiomatized theory in the language of arithmetic with $T \vdash \sigma$ for every $\sigma \in \mathrm{PA}$. Then $T \nvdash \mathrm{Con}_T$, where Con_T is the arithmetic sentence which expresses, via a Gödel numbering of formulas, that T is consistent.*

See [G̈31] and [Smi13].

Remark 2.8.10. Both theorems apply, with the same proofs, to any consistent computably axiomatized theory in which arithmetic can be interpreted, such as ZFC: if ZFC is consistent, it does not prove its own consistency [Kun11]. This affects the foundations of this project. In Chapter 3 we assume the existence of a Grothendieck universe, and a universe is a model of ZFC; so ZFC together with this assumption proves $\mathrm{Con}_{\mathrm{ZFC}}$. By the second incompleteness theorem, the existence of a universe can therefore not be proved in ZFC (if ZFC is consistent): it is a genuinely new axiom, of modest strength.

Example 2.8.11. *Natural independent statements.* The sentence of Gödel's proof is artificial, but later work found statements of ordinary mathematics that are independent.

1. *Goodstein sequences.* Write a number m in *hereditary base b*: as a sum of powers of b with coefficients less than b, with the exponents again written in hereditary base b, and so on. For instance $4 = 2^2$ and $26 = 2 \cdot 3^2 + 2 \cdot 3 + 2$ in hereditary bases 2 and 3. The Goodstein sequence of m starts with $m_2 = m$; to pass from m_b to m_{b+1}, write m_b in hereditary base b, replace every b by $b+1$, and subtract 1. Starting from $3 = 2 + 1$: replacing 2 by 3 gives 4, minus one is 3; then $3 = 3^1$ in base 3 becomes 4, minus one is 3; in base 4 the number 3 is a single digit, so the sequence continues $2, 1, 0$. Starting from $4 = 2^2$ the sequence grows quickly: 4, $3^3 - 1 = 26$, $2 \cdot 4^2 + 2 \cdot 4 + 2 - 1 = 41$, $2 \cdot 5^2 + 2 \cdot 5 + 1 - 1 = 60$, $2 \cdot 6^2 + 2 \cdot 6 - 1 = 83$, and so on. *Goodstein's theorem* [Goo44] says that every Goodstein sequence reaches 0. The proof replaces each base by the ordinal ω (Chapter 3): this turns the sequence into a strictly decreasing sequence of ordinals, which must be finite since ordinals are well-ordered. The theorem can be stated in the language of arithmetic and is true in $\mathcal{N}$, but it is not provable in PA [KP82]: any proof needs the well-ordering of ordinals beyond the reach of PA.

2. *The Paris–Harrington theorem*, a strengthening of the finite Ramsey theorem, is likewise true but not provable in PA [PH77].

3. In set theory, the continuum hypothesis is neither provable nor refutable in ZFC, if ZFC is consistent [G̈38, Coh63] (see Chapter 3). Unlike the examples above, its independence is proved by constructing models of ZFC in which it holds and models in which it fails, as in Proposition 2.8.6.

Remark 2.8.12. *Computability and Turing's theorem.* The informal notion of algorithm used in Definition 2.8.2 was made precise in the 1930s by Turing machines, recursive functions and the λ-calculus, which turned out to define the same class of computable functions (the *Church–Turing thesis* asserts that this class captures all effective procedures). *Turing's theorem* [Tur37] says that the *halting problem* is undecidable: there is no algorithm which, given a program P and an input x, decides whether P halts on x. The idea is a diagonal argument.

If H were such an algorithm, consider the program D which, on input a program P, runs H on (P, P) and loops forever if the answer is "halts", and halts otherwise; then D halts on input D if and only if it does not. The same diagonal mechanism, with provability in place of halting, underlies the first incompleteness theorem; and Turing's theorem implies that first-order validity is not decidable (Church and Turing's negative answer to Hilbert's *Entscheidungsproblem*), although by the completeness theorem the valid sentences can be listed by an algorithm.

2.9 Exercises

Exercise 2.9.1. Show that every function $\{0,1\}^n \to \{0,1\}$ with $n \geq 1$ is computed by a formula built from variables using only $\neg$ and $\wedge$ (as primitive connectives with their usual truth tables). Show that a formula built from variables using only $\wedge$, $\vee$ and $\to$ is satisfied by the truth assignment that is constantly 1, and deduce that these three connectives do not suffice to express negation.

Solution. By Lemma 2.2.8, $\varphi \vee \psi$ has the same truth table as $\neg(\neg\varphi \wedge \neg\psi)$ and $\varphi \to \psi$ the same as $\neg(\varphi \wedge \neg\psi)$; so the formula of Proposition 2.2.10 can be rewritten using $\neg$ and $\wedge$. For the second part, argue by induction: if v is constantly 1, then $\bar{v}$ is 1 on variables, and $1 \wedge 1$, $1 \vee 1$ and $1 \to 1$ all have value 1. Negation of a variable has value 0 under v, so it is not expressible. □

Exercise 2.9.2. Show that $\exists x \forall y\, \varphi \to \forall y \exists x\, \varphi$ is valid for every formula φ, and give a formula φ in the language of orders and a structure in which $\forall y \exists x\, \varphi \to \exists x \forall y\, \varphi$ is false.

Solution. Let $\mathcal{A}$ be a structure and s an assignment with $\mathcal{A} \models \exists x \forall y\, \varphi[s]$ (if x and y are the same variable the statement is trivial, so assume they are different). Then there is $a \in A$ with $\mathcal{A} \models \forall y\, \varphi[s[x \mapsto a]]$, that is, $\mathcal{A} \models \varphi[s[x \mapsto a][y \mapsto b]]$ for every $b \in A$. Given b, the element a witnesses $\mathcal{A} \models \exists x\, \varphi[s[y \mapsto b]]$, since $s[y \mapsto b][x \mapsto a] = s[x \mapsto a][y \mapsto b]$. So $\mathcal{A} \models \forall y \exists x\, \varphi[s]$. In words: one x that works for all y certainly gives, for each y, an x that works. The converse fails: in $(\mathbb{N}, <)$ with $\varphi = (y < x)$, the sentence $\forall y \exists x\, (y < x)$ is true (every number has a larger one) and $\exists x \forall y\, (y < x)$ is false (no number is larger than all numbers, itself included). □

Exercise 2.9.3. A *well-order* is a total order in which every nonempty subset has a least element. Show that there is no theory T in the language of orders whose models are exactly the well-ordered sets. (Hint: add constants $c_0, c_1, \ldots$ and the sentences $c_{n+1} < c_n$.)

Solution. Suppose T were such a theory, and let $T' = T \cup \{c_{n+1} < c_n : n \in \mathbb{N}\}$ in the language with the new constants. A finite subset of T' mentions only $c_0, \ldots, c_k$ for some k. The finite order $\{0, 1, \ldots, k\}$ is well-ordered, hence a model of T, and interpreting c_n as $k - n$ for $n \leq k$ and as 0 for $n > k$ satisfies the sentences $c_{n+1} < c_n$ with $n < k$. So every finite subset of T' is satisfiable, and by the compactness theorem (Theorem 2.7.1) T' has a model. Its underlying order is a model of T, hence well-ordered, but the set $\{c_n\}$ of interpretations of the constants has no least element, since $c_{n+1} < c_n$ for all n. This is a contradiction. The property "every nonempty subset has a least element" quantifies over subsets, which first-order logic cannot do. □

Exercise 2.9.4. A group is a *torsion group* if every element has finite order. Show that there is no theory in the language of groups whose models are exactly the torsion groups. Show, on the other hand, that for every $n \geq 1$ there is a single sentence whose models among groups are exactly the groups satisfying $g^n = e$ for all g.

Solution. Suppose T were such a theory. Add a constant c and let $T' = T \cup \{c^n \neq e : n \geq 1\}$, where c^n is the term $c \cdot c \cdots c$ with n factors. A finite subset of T' involves only $n < N$ for some N, and is satisfied by the cyclic group $\mathbb{Z}/N\mathbb{Z}$ (written multiplicatively) with c a generator: it is a torsion group, hence a model of T, and $c^n \neq e$ for $0 < n < N$. By compactness T' has a model, a torsion group in which c has infinite order, a contradiction. For the second statement take the sentence $\forall x\,(x^n = e)$ together with the group axioms. So "all elements have order dividing n" is first-order for each fixed n, but "all elements have finite order" would be the infinite disjunction over all n, which is not a formula. □

Exercise 2.9.5. Let T_0 be the theory of fields in the language of rings, and for a prime p let χ_p be the sentence $\underline{p} \neq 0$, where $\underline{p}$ is $1 + 1 + \cdots + 1$ with p summands. The models of $T_0 \cup \{\chi_p : p \text{ prime}\}$ are the fields of characteristic zero. Show that there is no single sentence σ such that the models of $T_0 \cup \{\sigma\}$ are exactly the fields of characteristic zero. Deduce that a sentence true in all fields of characteristic zero is true in all fields of sufficiently large prime characteristic.

Solution. We first prove the second statement. Let τ be true in all fields of characteristic zero, so that $T_0 \cup \{\chi_p : p \text{ prime}\} \cup \{\neg\tau\}$ has no model. By the compactness theorem some finite subset has no model; enlarging it, $T_0 \cup \{\chi_p : p \leq N\} \cup \{\neg\tau\}$ has no model for some N. A field of prime characteristic $q > N$ satisfies T_0 and χ_p for $p \leq N$, so it does not satisfy $\neg\tau$: τ is true in it.

Now suppose the models of $T_0 \cup \{\sigma\}$ are the fields of characteristic zero. Then σ is true in all fields of characteristic zero, hence, by what we just proved, in $\mathbb{F}_q = \mathbb{Z}/q\mathbb{Z}$ for a large prime q; so $\mathbb{F}_q$ is a model of $T_0 \cup \{\sigma\}$ of characteristic q, a contradiction. For example, the sentence "$1 + 1 \neq 0$" is true in characteristic zero and fails only in characteristic 2, in accordance with the statement. □

Exercise 2.9.6. Let T be a theory and σ a sentence with $T \models \sigma$. Show, without using deductions, that some finite subset $T_0 \subseteq T$ satisfies $T_0 \models \sigma$ (for $\mathcal{L}$ countable).

Solution. Otherwise, for every finite $T_0 \subseteq T$ the set $T_0 \cup \{\neg\sigma\}$ has a model. Then every finite subset of $T \cup \{\neg\sigma\}$ is satisfiable, so by Theorem 2.7.1 the whole set has a model, which is a model of T in which σ is false, contradicting $T \models \sigma$. □

Chapter 3

Set Theory

3.1 Introduction

This chapter sets up the foundations of the project: Zermelo–Fraenkel set theory with the axiom of choice (ZFC), formulated as a first-order theory in the sense of Chapter 2. We develop the basic constructions (relations, functions, quotients), the natural numbers, ordinals and cardinals, prove the equivalence of the axiom of choice with Zorn's lemma and the well-ordering theorem, and discuss Grothendieck universes, which provide the conventions on size used throughout the project (Notation 1.7.1).

Standard references are [Jec03] and [Kun11]; [Hal60] is an informal introduction.

Prerequisites. Chapter 2 (Mathematical Logic).

On the way to the Hodge conjecture. Read Sections 3.2, 3.3, 3.4, 3.6 and Section 3.7 (for Zorn's lemma), and the first results on ordinals in Section 3.5. Universes (Section 3.8) are needed only for the set-theoretic foundations of category theory and can be skimmed.

Remark 3.1.1. Set theory is the first-order theory, in the language with one binary relation symbol $\in$ (Example 2.3.5), whose axioms are listed in Definition 3.2.1. Its models have a universe whose elements are called *sets*. We write statements in ordinary mathematical language, but each of them can be translated into a formula of this language, and each "construction" is justified by the axioms. A *class* is given by a formula $\varphi(x)$, possibly with parameters, and we write $\{x : \varphi(x)\}$ for it; a class need not be a set. Statements about classes are abbreviations of statements about the corresponding formulas.

3.2 The axioms

We use the abbreviations $x \subseteq y$ for $\forall z\,(z \in x \to z \in y)$, $\forall z \in x\,\varphi$ for $\forall z\,(z \in x \to \varphi)$ and $\exists z \in x\,\varphi$ for $\exists z\,(z \in x \wedge \varphi)$.

Definition 3.2.1. The axioms of *Zermelo–Fraenkel set theory* ZF are the following sentences.

1. (Extensionality) $\forall x \forall y\,(\forall z\,(z \in x \leftrightarrow z \in y) \to x = y)$.
2. (Foundation) $\forall x\,(\exists y\,(y \in x) \to \exists y \in x\,\neg\exists z\,(z \in x \wedge z \in y))$.
3. (Separation) For every formula φ in which y is not free: $\forall w_1 \cdots \forall w_n \forall x \exists y \forall z\,(z \in y \leftrightarrow (z \in x \wedge \varphi))$, where $w_1, \ldots, w_n$ are the other free variables of φ.
4. (Pairing) $\forall x \forall y \exists z\,(x \in z \wedge y \in z)$.
5. (Union) $\forall F \exists A \forall Y \forall x\,((x \in Y \wedge Y \in F) \to x \in A)$.

6. (Replacement) For every formula φ in which B is not free: $\forall w_1 \cdots \forall w_n \forall A \left(\forall x \in A \, \exists! y \, \varphi \to \exists B \, \forall x \in A \, \exists y \in B \, \varphi\right)$, where $\exists! y \, \varphi$ abbreviates "there is exactly one y with φ" and $w_1, \ldots, w_n$ are the other free variables of φ.

7. (Infinity) $\exists x \left(\exists e \in x \, \forall z \, (z \notin e) \wedge \forall y \in x \, \exists s \in x \, \forall z \, (z \in s \leftrightarrow (z \in y \vee z = y))\right)$.

8. (Power set) $\forall x \exists y \forall z \, (z \subseteq x \to z \in y)$.

The theory ZFC consists of ZF together with the axiom of choice, Definition 3.7.1. The axioms of separation and replacement are *schemas*: they consist of one axiom for each formula φ.

Remark 3.2.2. Extensionality says that a set is determined by its elements. Separation says that for a set x and a property φ, the elements of x with the property form a set, written $\{z \in x : \varphi(z)\}$. Pairing, union and power set provide sets containing the pair $\{x, y\}$, the union of the elements of F, and the subsets of x; by separation and extensionality there are then unique sets with exactly these elements. Replacement says that the image of a set under a class function is contained in a set. Infinity provides a set containing $\emptyset$ and closed under $y \mapsto y \cup \{y\}$. Foundation says that every nonempty set has an $\in$-minimal element.

Lemma 3.2.3. *1. There is a unique set $\emptyset$ with no elements.*

2. For all sets x, y there are unique sets $\{x, y\}$, $\bigcup x$ and $\mathcal{P}(x)$ with, respectively, the elements x and y; the elements of elements of x; the subsets of x.

3. For all sets x, y there are unique sets $x \cup y$, $x \cap y$ and $x \setminus y$ with the usual elements. If F is a nonempty set, there is a unique set $\bigcap F$ whose elements are the sets belonging to every element of F.

Proof. Uniqueness always follows from extensionality. (1) Some set x exists, because $\exists x \, (x = x)$ is valid (structures are nonempty); apply separation with the formula $z \neq z$. (2) Apply separation to the sets given by pairing, union and power set, with the formulas $z = x \vee z = y$, $\exists Y \in x \, (z \in Y)$ and $z \subseteq x$. (3) Put $x \cup y = \bigcup \{x, y\}$, and use separation on x for $x \cap y$ and $x \setminus y$. If $X \in F$, put $\bigcap F = \{z \in X : \forall Y \in F \, (z \in Y)\}$. □

Proposition 3.2.4 (Russell)**.** *There is no set of which every set is an element.*

Proof. Suppose V is such a set and let $R = \{x \in V : x \notin x\}$. Then $R \in V$, so $R \in R$ if and only if $R \notin R$, a contradiction. □

Remark 3.2.5. So the class $\{x : x = x\}$ of all sets is not a set; such classes are called *proper classes*. Proposition 3.2.4 holds even without foundation. With foundation it is also immediate from Lemma 3.2.6.

Lemma 3.2.6. *There is no set x with $x \in x$, and there are no sets x, y with $x \in y$ and $y \in x$.*

Proof. If $x \in x$, the set $\{x\}$ has no $\in$-minimal element: its only element x satisfies $x \in x \cap \{x\}$. If $x \in y \in x$, the set $\{x, y\}$ has no $\in$-minimal element, since $y \in x \cap \{x, y\}$ and $x \in y \cap \{x, y\}$. □

3.3 Relations and functions

Definition 3.3.1. The *ordered pair* of a and b is $(a, b) = \{\{a\}, \{a, b\}\}$.

Lemma 3.3.2. *$(a, b) = (c, d)$ if and only if $a = c$ and $b = d$.*

Proof. Suppose $(a,b) = (c,d)$. If $a = b$, then $(a,b) = \{\{a\}\}$, so $\{c\} = \{c,d\} = \{a\}$ and $a = b = c = d$. Similarly if $c = d$. Assume $a \neq b$ and $c \neq d$. Then $\{a\}$ is the only one-element set in (a,b), and $\{c\}$ the only one in (c,d), so $\{a\} = \{c\}$ and $a = c$. The two-element sets $\{a,b\}$ and $\{c,d\} = \{a,d\}$ are then equal, and since $b \neq a$ we get $b = d$. The converse is clear. □

Definition 3.3.3. The *cartesian product* of sets A and B is $A \times B = \{p \in \mathcal{P}(\mathcal{P}(A \cup B)) : \exists a \in A\, \exists b \in B\, p = (a,b)\}$. It is a set by separation, and its elements are exactly the pairs (a,b) with $a \in A$, $b \in B$, because $\{a\}$ and $\{a,b\}$ are subsets of $A \cup B$.

Definition 3.3.4. A *relation* from A to B is a subset $R \subseteq A \times B$; we write aRb for $(a,b) \in R$. A *function* (or *map*) $f : A \to B$ is a relation $f \subseteq A \times B$ such that for every $a \in A$ there is exactly one $b \in B$ with $(a,b) \in f$, written $b = f(a)$. (Formally, a function records its target: it is the triple (A,B,f); we shall not insist on this.) For $X \subseteq A$ and $Y \subseteq B$, the *image* is $f[X] = \{f(a) : a \in X\}$ and the *preimage* is $f^{-1}[Y] = \{a \in A : f(a) \in Y\}$. The function is *injective*, *surjective* or *bijective* if it is so as a map in the usual sense. The composition $g \circ f$ of $f : A \to B$ and $g : B \to C$ is $\{(a,c) \in A \times C : \exists b\, ((a,b) \in f \wedge (b,c) \in g)\}$. The set of all functions from A to B is $B^A = \{f \in \mathcal{P}(A \times B) : f \text{ is a function } A \to B\}$.

Definition 3.3.5. A *family* $(x_i)_{i \in I}$ is a function $i \mapsto x_i$ with domain I. Its union is $\bigcup_{i \in I} x_i = \bigcup \{x_i : i \in I\}$, which is a set: the image of I under the family is a set by replacement and separation. Its *product* is the set $\prod_{i \in I} x_i = \{f \in (\bigcup_{i \in I} x_i)^I : f(i) \in x_i \text{ for all } i \in I\}$.

Lemma 3.3.6. *A function $f : A \to B$ is bijective if and only if there is a function $g : B \to A$ with $g \circ f = \mathrm{id}_A$ and $f \circ g = \mathrm{id}_B$; such a g is unique.*

Proof. If f is bijective, $g = \{(b,a) : (a,b) \in f\}$ is a function $B \to A$ with the two properties. Conversely, $g \circ f = \mathrm{id}_A$ implies that f is injective and $f \circ g = \mathrm{id}_B$ that f is surjective. If g' also has the properties, then $g' = g' \circ f \circ g = g$. □

Definition 3.3.7. An *equivalence relation* on A is a relation $\sim$ from A to A that is reflexive, symmetric and transitive. The *class* of $a \in A$ is $[a] = \{x \in A : x \sim a\}$, and the *quotient* is the set $A/\!\sim = \{X \in \mathcal{P}(A) : \exists a \in A\, X = [a]\}$, with the *projection* $\pi : A \to A/\!\sim$, $a \mapsto [a]$. A *partition* of A is a set of nonempty, pairwise disjoint subsets of A whose union is A.

Proposition 3.3.8. *Let A be a set. The map $\sim \mapsto A/\!\sim$ is a bijection from the set of equivalence relations on A to the set of partitions of A. Its inverse sends a partition Π to the relation "x and y lie in the same element of Π".*

Proof. If $\sim$ is an equivalence relation, the classes are nonempty ($a \in [a]$) and cover A. If $z \in [a] \cap [b]$, then $z \sim a$ and $z \sim b$, so $a \sim b$ by symmetry and transitivity, and then $[a] = [b]$. So $A/\!\sim$ is a partition. Conversely, the relation defined by a partition Π is clearly an equivalence relation whose classes are the elements of Π, and $x \sim y$ if and only if x and y lie in the same class of $\sim$. So the two constructions are inverse to each other. □

Proposition 3.3.9. *Let $\sim$ be an equivalence relation on A and $f : A \to B$ a map such that $a \sim a'$ implies $f(a) = f(a')$. There is a unique map $\bar{f} : A/\!\sim \to B$ with $\bar{f} \circ \pi = f$.*

Proof. Uniqueness holds because π is surjective. Put $\bar{f} = \{(X,b) \in (A/\!\sim) \times B : \exists a \in X\, f(a) = b\}$. Every class X is nonempty, and all its elements have the same image under f, so $\bar{f}$ is a function, and $\bar{f}([a]) = f(a)$. □

Definition 3.3.10. A *partial order* on A is a relation $\leq$ that is reflexive, antisymmetric and transitive; it is *total* if $x \leq y$ or $y \leq x$ for all x, y. We write $x < y$ for $x \leq y \wedge x \neq y$. A *chain* is a totally ordered subset. For $X \subseteq A$, an *upper bound* of X is an $a \in A$ with $x \leq a$ for all $x \in X$;

a *least upper bound* or *supremum* is an upper bound below all upper bounds. An element m is *maximal* if there is no x with $m < x$, and *greatest* if $x \le m$ for all x. A *well-order* is a total order in which every nonempty subset has a least element. An *isomorphism* of ordered sets is a bijection f with $x \le y \iff f(x) \le f(y)$. For $a \in A$, the *initial segment* determined by a is $A_{<a} = \{x \in A : x < a\}$.

Counterexample 3.3.11. A maximal element need not be greatest, and a greatest element need not exist. In $\{\{0\}, \{1\}\}$, ordered by inclusion, both elements are maximal and there is no greatest element.

Lemma 3.3.12. *Let W be a well-ordered set and $f : W \to W$ a strictly increasing map. Then $f(w) \ge w$ for all $w \in W$. Consequently, W is not isomorphic to any initial segment $W_{<a}$, and the only isomorphism $W \to W$ is the identity. If two well-ordered sets are isomorphic, the isomorphism is unique.*

Proof. If $\{w : f(w) < w\}$ is nonempty, let w be its least element. Then $f(w) < w$, so $f(f(w)) < f(w)$, and $f(w)$ is a smaller element of the same set; contradiction. An isomorphism $f : W \to W_{<a}$ would give a strictly increasing $W \to W$ with $f(a) < a$. If $f, g : W \to W'$ are isomorphisms, $g^{-1} \circ f$ and $f^{-1} \circ g$ are strictly increasing, so $f(w) \ge g(w)$ and $g(w) \ge f(w)$ for all w. □

3.4 The natural numbers

Definition 3.4.1. The *successor* of a set x is $S(x) = x \cup \{x\}$. A set I is *inductive* if $\emptyset \in I$ and $S(y) \in I$ for all $y \in I$. By the axiom of infinity there is an inductive set I_0, and we define

$$\omega = \{n \in I_0 : n \in I \text{ for every inductive set } I\}.$$

The elements of ω are the *natural numbers*; we write $\mathbb{N} = \omega$, $0 = \emptyset$, $1 = S(0)$, $2 = S(1)$, and so on.

Theorem 3.4.2 (Induction)**.** *The set ω is inductive and is contained in every inductive set; it does not depend on the choice of I_0. If $X \subseteq \omega$ contains 0 and $S(n) \in X$ for all $n \in X$, then $X = \omega$.*

Proof. Every inductive set contains $\emptyset$ and is closed under S, so the intersection ω has the same two properties; it is contained in every inductive set by definition. If I_1 is another inductive set, the set defined using I_1 is contained in I_0 and has the same elements. A set X as in the statement is inductive, so $\omega \subseteq X$. □

Remark 3.4.3. In this construction 0 is a natural number, and there is a good reason for it. The construction needs a first set to start from, and the only set that the axioms provide without any choices is $\emptyset$. With $0 = \emptyset$, each natural number is the set of its predecessors, $n = \{0, 1, \ldots, n-1\}$, so n is a set with exactly n elements: 0 counts the empty set, and "X has n elements" will mean that X is in bijection with n (Definition 3.6.4). Moreover 0 is the neutral element of addition (Example 3.4.7), so with $0 \in \mathbb{N}$ the natural numbers form a monoid under addition, and every natural number is a sum of ones, the empty sum being 0. For these reasons $\mathbb{N} = \{0, 1, 2, \ldots\}$ throughout the project. Many texts, especially in analysis and number theory, let $\mathbb{N}$ start at 1; when we need the positive integers we write $\mathbb{N}_{>0} = \{1, 2, 3, \ldots\}$, so a sequence indexed by $\mathbb{N}_{>0}$ starts with its term of index 1.

Lemma 3.4.4. *Every element of a natural number is a natural number, and every natural number n is* transitive*: if $y \in x \in n$ then $y \in n$.*

Proof. Let X be the set of $n \in \omega$ such that $n \subseteq \omega$ and n is transitive. Clearly $0 \in X$. If $n \in X$, then $S(n) = n \cup \{n\} \subseteq \omega$; and if $y \in x \in S(n)$, then either $x \in n$, so $y \in n$, or $x = n$, so $y \in n$; in both cases $y \in S(n)$. By Theorem 3.4.2, $X = \omega$. □

Proposition 3.4.5 (Peano axioms)**.** *For all $m, n \in \omega$: $S(n) \neq 0$, and $S(m) = S(n)$ implies $m = n$.*

Proof. $n \in S(n)$, so $S(n) \neq \emptyset$. Suppose $S(m) = S(n)$ and $m \neq n$. Since $m \in S(n)$, we get $m \in n$; similarly $n \in m$. This contradicts Lemma 3.2.6. □

Theorem 3.4.6 (Recursion)**.** *Let A be a set, $a \in A$ and $g \colon \omega \times A \to A$ a map. There is a unique map $f \colon \omega \to A$ with $f(0) = a$ and $f(S(n)) = g(n, f(n))$ for all $n \in \omega$.*

Proof. Call a map h *acceptable* if its domain is $S(k)$ for some $k \in \omega$, its values lie in A, $h(0) = a$, and $h(S(i)) = g(i, h(i))$ whenever $S(i) \in \mathrm{dom}(h)$. Acceptable maps are elements of $\mathcal{P}(\omega \times A)$, so they form a set H.

If $h, h' \in H$ and i lies in both domains, then $h(i) = h'(i)$. Indeed, let X be the set of $i \in \omega$ such that this holds whenever $i \in \mathrm{dom}(h) \cap \mathrm{dom}(h')$. Then $0 \in X$. If $i \in X$ and $S(i)$ lies in both domains, then so does i, because domains are transitive (Lemma 3.4.4), and $h(S(i)) = g(i, h(i)) = g(i, h'(i)) = h'(S(i))$. So $X = \omega$.

Hence $f = \bigcup H$ is a function with values in A. Every $n \in \omega$ lies in its domain: by induction there is an acceptable h_n with domain $S(n)$, since $\{(0, a)\}$ is acceptable with domain $S(0)$, and if h is acceptable with domain $S(n)$ then $h \cup \{(S(n), g(n, h(n)))\}$ is acceptable with domain $S(S(n))$. Then $f(0) = a$, and $f(S(n)) = h_{S(n)}(S(n)) = g(n, h_{S(n)}(n)) = g(n, f(n))$. If f' is another such map, induction shows $f(n) = f'(n)$ for all n. □

Example 3.4.7. By Theorem 3.4.6, for each $m \in \omega$ there are unique maps $n \mapsto m + n$ and $n \mapsto m \cdot n$ with $m + 0 = m$, $m + S(n) = S(m + n)$, $m \cdot 0 = 0$ and $m \cdot S(n) = m \cdot n + m$. So $(\omega, 0, S, +, \cdot)$ is a model of Robinson arithmetic Q (Definition 2.8.1). The laws of arithmetic are proved in Chapter 4.

3.5 Ordinals

Definition 3.5.1. A set x is *transitive* if every element of x is a subset of x. An *ordinal* is a transitive set α such that the relation $\{(\beta, \gamma) \in \alpha \times \alpha : \beta \in \gamma\}$ is a strict well-order on α: it is transitive, for all $\beta, \gamma \in \alpha$ exactly one of $\beta \in \gamma$, $\beta = \gamma$, $\gamma \in \beta$ holds, and every nonempty subset of α has an $\in$-least element. For ordinals we write $\beta < \gamma$ for $\beta \in \gamma$. The class of ordinals is denoted Ord.

Lemma 3.5.2. *Every element of an ordinal is an ordinal, and $\alpha \notin \alpha$ for every ordinal α.*

Proof. Let $\beta \in \alpha$. Then $\beta \subseteq \alpha$, so $\in$ is a strict well-order on β. If $\delta \in \gamma \in \beta$, then γ and δ lie in α, and transitivity of the order on α gives $\delta \in \beta$; so β is transitive. The last statement is Lemma 3.2.6. □

Lemma 3.5.3. *If α and β are ordinals with $\alpha \subsetneq \beta$, then $\alpha \in \beta$.*

Proof. Let γ be the least element of $\beta \setminus \alpha$. If $\delta \in \gamma$, then $\delta \in \beta$ and $\delta < \gamma$, so $\delta \in \alpha$ by minimality; hence $\gamma \subseteq \alpha$. If $\delta \in \alpha$, then $\delta \in \beta$; $\delta = \gamma$ is impossible since $\gamma \notin \alpha$, and $\gamma \in \delta$ is impossible since it would give $\gamma \in \alpha$ by transitivity of α; so $\delta \in \gamma$. Hence $\alpha = \gamma \in \beta$. □

Theorem 3.5.4. *For all ordinals α, β, exactly one of $\alpha < \beta$, $\alpha = \beta$, $\beta < \alpha$ holds. Every nonempty set X of ordinals has a least element, namely $\bigcap X$, and $\sup X = \bigcup X$ is an ordinal which is the least ordinal $\geq$ every element of X.*

Proof. The set $\gamma = \alpha \cap \beta$ is transitive and a subset of α, hence an ordinal. By Lemma 3.5.3, $\gamma = \alpha$ or $\gamma \in \alpha$, and $\gamma = \beta$ or $\gamma \in \beta$. If $\gamma \in \alpha$ and $\gamma \in \beta$, then $\gamma \in \gamma$, contradicting Lemma 3.5.2. So $\alpha \subseteq \beta$ or $\beta \subseteq \alpha$, and the first claim follows from Lemma 3.5.3; at most one of the three holds by Lemma 3.2.6.

Let $\alpha \in X$. If no element of X is smaller than α, then α is least. Otherwise $\alpha \cap X$ is a nonempty subset of α and has a least element, which is least in X. By the first part, the least element is contained in every element of X, so it equals $\bigcap X$. Finally $\bigcup X$ is a transitive set of ordinals; by the first part $\in$ is a strict total order on it, and every nonempty subset has a least element; so it is an ordinal. It contains each $\alpha \in X$ as a subset, and any ordinal containing all $\alpha \in X$ as subsets contains $\bigcup X$. □

Proposition 3.5.5 (Burali-Forti)**.** *There is no set containing all ordinals.*

Proof. If X were such a set, $\Omega = \{x \in X : x \text{ is an ordinal}\}$ would be a transitive set (Lemma 3.5.2) well-ordered by $\in$ (Theorem 3.5.4), hence an ordinal, so $\Omega \in \Omega$. □

Definition 3.5.6. For an ordinal α, the set $\alpha + 1 = S(\alpha)$ is an ordinal, the least ordinal greater than α. An ordinal is a *successor ordinal* if it is of the form $\alpha + 1$, and a *limit ordinal* if it is neither 0 nor a successor ordinal.

Proposition 3.5.7. *Every natural number is an ordinal, ω is an ordinal, and ω is the least limit ordinal. On ω the order $m < n$ (that is, $m \in n$) is a well-order.*

Proof. $\emptyset$ is an ordinal, and if α is an ordinal so is $S(\alpha)$ (it is transitive, and its elements are the ordinals in α together with α). By induction every natural number is an ordinal. By Lemma 3.4.4, ω is a transitive set of ordinals, hence an ordinal by Theorem 3.5.4. It is not 0, and not a successor, since $S(n) \in \omega$ for $n \in \omega$. If λ is a limit ordinal, then $0 \in \lambda$, and for $n \in \lambda$ we have $S(n) \leq \lambda$ and $S(n) \neq \lambda$, so $S(n) \in \lambda$; thus λ is inductive and $\omega \subseteq \lambda$. □

Theorem 3.5.8 (Transfinite induction)**.** *Let C be a class. Suppose that for every ordinal α, if all ordinals $\beta < \alpha$ belong to C, then α belongs to C. Then every ordinal belongs to C.*

Proof. Otherwise let α be an ordinal not in C. The set $\{\beta \in \alpha + 1 : \beta \notin C\}$ is nonempty, and its least element β satisfies the hypothesis, so $\beta \in C$; contradiction. □

Theorem 3.5.9 (Transfinite recursion)**.** *Let G be a class function, that is, a formula $\psi(x, y)$ such that for every x there is exactly one y with $\psi(x, y)$, written $y = G(x)$. There is a unique class function F defined on all ordinals such that $F(\alpha) = G(F|_\alpha)$ for every ordinal α, where $F|_\alpha = \{(\beta, F(\beta)) : \beta < \alpha\}$.*

Proof. As usual for class functions, the theorem is a schema: for each ψ we write down a formula defining F and prove its properties. Call a function f an *α-attempt* if its domain is the ordinal α and $f(\beta) = G(f|_\beta)$ for all $\beta < \alpha$. By transfinite induction on β, two attempts agree on the intersection of their domains.

We show by transfinite induction that an α-attempt exists for every α. Suppose that for each $\beta < \alpha$ there is a β-attempt f_β, which is unique. By replacement, $\{f_\beta : \beta < \alpha\}$ is a set. If $\alpha = \beta + 1$, then $f_\beta \cup \{(\beta, G(f_\beta))\}$ is an α-attempt. If α is 0 or a limit ordinal, then $\bigcup_{\beta<\alpha} f_\beta$ is a function (the f_β agree on common domains) with domain $\bigcup_{\beta<\alpha} \beta = \alpha$, and it is an α-attempt.

Define $F(\alpha) = G(f)$, where f is the α-attempt; then $F|_\alpha = f$ and $F(\alpha) = G(F|_\alpha)$. Uniqueness of F follows by transfinite induction. □

Theorem 3.5.10. *Every well-ordered set $(W, <)$ is isomorphic to a unique ordinal, by a unique isomorphism.*

Proof. Uniqueness follows from Lemma 3.3.12: two isomorphic ordinals are equal, since otherwise one is an initial segment of the other. Let A be the set of $w \in W$ such that $W_{<w}$ is isomorphic to some ordinal, necessarily unique, which we call α_w. By replacement, $\alpha = \{\alpha_w : w \in A\}$ is a set. If $v < w \in A$, the isomorphism $W_{<w} \to \alpha_w$ restricts to an isomorphism from $W_{<v}$ to an initial segment of α_w, which is an ordinal; so $v \in A$ and $\alpha_v < \alpha_w$. Hence A is an initial segment of W or equal to W, α is a transitive set of ordinals, hence an ordinal, and $w \mapsto \alpha_w$ is an isomorphism $A \to \alpha$. If $A \neq W$, let w be the least element of $W \setminus A$; then $A = W_{<w}$, so $w \in A$, a contradiction. □

Definition 3.5.11. By transfinite recursion, define sets V_α for all ordinals by $V_0 = \emptyset$, $V_{\alpha+1} = \mathcal{P}(V_\alpha)$ and $V_\lambda = \bigcup_{\alpha<\lambda} V_\alpha$ for limit ordinals λ.

Lemma 3.5.12. *Every V_α is transitive, and $V_\beta \subseteq V_\alpha$ for $\beta \leq \alpha$. A set x lies in $V_{\alpha+1}$ if and only if $x \subseteq V_\alpha$.*

Proof. The last statement is the definition. We prove the first two statements together by transfinite induction on α. For $\alpha = 0$ they are clear, and for limit α they follow from the induction hypothesis. Let $\alpha = \gamma + 1$. If $x \in V_\alpha$ and $y \in x$, then $y \in V_\gamma$, so $y \subseteq V_\gamma$ by transitivity of V_γ, that is, $y \in V_\alpha$. Also $V_\gamma \subseteq V_\alpha$, because each element of V_γ is a subset of V_γ; combined with the induction hypothesis this gives $V_\beta \subseteq V_\alpha$ for all $\beta \leq \alpha$. □

Lemma 3.5.13. *Every set x is a subset of a transitive set.*

Proof. Apply Theorem 3.5.9 to the class function G with $G(f) = \bigcup f(n)$ if f is a function whose domain is $S(n)$ for some $n \in \omega$, and $G(f) = x$ otherwise. The resulting F satisfies $F(0) = x$ and $F(n+1) = \bigcup F(n)$ for $n \in \omega$. By replacement, $\{F(n) : n \in \omega\}$ is a set; let T be its union. Then $x \subseteq T$, and if $z \in y \in T$, say $y \in F(n)$, then $z \in F(n+1) \subseteq T$. □

Theorem 3.5.14. *Every set belongs to V_α for some ordinal α.*

Proof. Suppose x belongs to no V_α. Let T be a transitive set containing $\{x\}$ as a subset (Lemma 3.5.13) and let $Y = \{y \in T : y \notin V_\alpha \text{ for all } \alpha\}$; then $x \in Y$. By foundation there is $y \in Y$ with $y \cap Y = \emptyset$. Each $z \in y$ lies in T but not in Y, so there is a least ordinal α_z with $z \in V_{\alpha_z}$. By replacement, $\{\alpha_z : z \in y\}$ is a set; let α be its supremum. Then $y \subseteq V_\alpha$ by Lemma 3.5.12, so $y \in V_{\alpha+1}$, a contradiction. □

Definition 3.5.15. The *rank* $\mathrm{rk}(x)$ of a set x is the least ordinal α with $x \subseteq V_\alpha$.

3.6 Cardinality

Definition 3.6.1. Sets A and B are *equinumerous*, written $A \approx B$, if there is a bijection $A \to B$. We write $A \preceq B$ if there is an injection $A \to B$, and $A \prec B$ if $A \preceq B$ and not $A \approx B$.

Theorem 3.6.2 (Cantor–Schröder–Bernstein)**.** *If $A \preceq B$ and $B \preceq A$, then $A \approx B$.*

Proof. Let $f : A \to B$ and $g : B \to A$ be injections. Define $C_0 = A \setminus g[B]$ and $C_{n+1} = g[f[C_n]]$ by recursion, and let $C = \bigcup_n C_n$. Define $h : A \to B$ by $h(a) = f(a)$ if $a \in C$, and $h(a) = g^{-1}(a)$ if $a \notin C$; this makes sense because $a \notin C$ implies $a \in g[B]$, and g is injective.

h is surjective: let $b \in B$. If $g(b) \notin C$, then $h(g(b)) = b$. If $g(b) \in C$, then $g(b) \notin C_0$, so $g(b) \in C_{n+1}$ for some n, that is, $g(b) = g(f(c))$ with $c \in C_n$; then $b = f(c) = h(c)$.

h is injective: f and g^{-1} are injective, so it suffices to exclude $f(a) = g^{-1}(a')$ with $a \in C$ and $a' \notin C$. But then $a' = g(f(a)) \in C$ since $a \in C_n$ implies $g(f(a)) \in C_{n+1}$. □

Theorem 3.6.3 (Cantor)**.** *For every set A there is no surjection $A \to \mathcal{P}(A)$. In particular $A \prec \mathcal{P}(A)$.*

Proof. Let $f : A \to \mathcal{P}(A)$ and $D = \{a \in A : a \notin f(a)\}$. If $D = f(d)$, then $d \in D$ if and only if $d \notin D$. So f is not surjective. The map $a \mapsto \{a\}$ is an injection $A \to \mathcal{P}(A)$. □

Definition 3.6.4. A set is *finite* if it is equinumerous with some $n \in \omega$, and *infinite* otherwise. It is *countable* if $A \preceq \omega$, and *countably infinite* if $A \approx \omega$.

Proposition 3.6.5 (Pigeonhole principle)**.** *For $n \in \omega$ there is no injection $n+1 \to n$. Consequently, if $m \neq n$ are natural numbers then $m \not\approx n$, and ω is infinite.*

Proof. For $n = 0$ there is no map from $1 = \{0\}$ to $\emptyset$. Suppose there is no injection $n+1 \to n$, and let $f : n+2 \to n+1$ be injective. Let τ be the bijection of $n+1$ exchanging n and $f(n+1)$. Then $\tau \circ f$ is injective and sends $n+1$ to n, so it restricts to an injection $n+1 \to (n+1)\setminus\{n\} = n$, a contradiction. If $m < n$, then $m+1 \subseteq n$, so an injection $n \to m$ would give one $m+1 \to m$. Finally $\omega \approx n$ would give an injection $n+1 \to n$. □

Proposition 3.6.6. *Every subset of a natural number is finite, and every subset of ω is finite or countably infinite. A set is countable if and only if it is finite or countably infinite.*

Proof. By induction on n: subsets of 0 are finite, and a subset X of $n+1$ is $X \cap n$ or $(X \cap n) \cup \{n\}$; if $X \cap n \approx k$ then $(X \cap n) \cup \{n\} \approx k+1$.

Let $X \subseteq \omega$ be infinite. Then X has no upper bound in ω (otherwise $X \subseteq m$ for some m, and X would be finite). Define $e(0) = \min X$ and $e(n+1) = \min\{x \in X : x > e(n)\}$ by recursion. Then e is strictly increasing, hence injective, and $e(n) \geq n$ by induction. Given $x \in X$, let n be least with $e(n) \geq x$. If $n = 0$ then $x \leq e(0) = \min X \leq x$. If $n > 0$ then $e(n-1) < x$, so $e(n) \leq x$ by definition of $e(n)$. In both cases $x = e(n)$, so $e : \omega \to X$ is a bijection. The last statement follows: a set injecting into ω is equinumerous with a subset of ω. □

Definition 3.6.7. An ordinal κ is a *cardinal* if no $\beta < \kappa$ is equinumerous with κ. If A is equinumerous with some ordinal (for instance if A can be well-ordered, by Theorem 3.5.10), its *cardinality* $|A|$ is the least ordinal equinumerous with A; it is a cardinal.

Example 3.6.8. By Proposition 3.6.5, every natural number and ω are cardinals, and a finite set A has $|A| \in \omega$, its number of elements. The ordinal $\omega + 1$ is not a cardinal: $n \mapsto n+1$ for $n \in \omega$ and $\omega \mapsto 0$ define a bijection $\omega + 1 \to \omega$.

Theorem 3.6.9 (Hartogs)**.** *For every set A there is an ordinal $h(A)$ that does not inject into A; the least such ordinal is a cardinal. This uses no form of the axiom of choice.*

Proof. Let $\mathcal{W}$ be the set of pairs $(X, R) \in \mathcal{P}(A) \times \mathcal{P}(A \times A)$ such that R is a well-order on X. By Theorem 3.5.10 and replacement, the order types of these well-orders form a set H. An ordinal α injects into A if and only if $\alpha \in H$ (transport the order of α to the image). If $\alpha \in H$ and $\beta < \alpha$, then $\beta \in H$; so H is a transitive set of ordinals, hence an ordinal, and $H \notin H$. Put $h(A) = H$; it is the least ordinal not injecting into A. If some $\beta < H$ were equinumerous with H, then H would inject into A through β. □

Definition 3.6.10. By transfinite recursion let $\omega_0 = \omega$, $\omega_{\alpha+1} = h(\omega_\alpha)$ and $\omega_\lambda = \sup_{\alpha<\lambda} \omega_\alpha$ for limit λ. We also write $\aleph_\alpha$ for ω_α when we think of it as a cardinality.

Proposition 3.6.11. *The ω_α are cardinals, $\alpha < \beta$ implies $\omega_\alpha < \omega_\beta$, and every infinite cardinal equals ω_α for a unique α.*

Proof. Strict monotonicity is clear from the definition, because $\omega_\alpha < h(\omega_\alpha)$. By induction $\alpha \leq \omega_\alpha$. A supremum λ of cardinals is a cardinal: if $\beta < \lambda$ then $\beta < \kappa \leq \lambda$ for one of the cardinals κ, and $\beta \approx \lambda$ would give $\kappa \preceq \beta$ and hence $\kappa \approx \beta$ by Theorem 3.6.2. With Theorem 3.6.9, all ω_α are cardinals.

Let κ be an infinite cardinal, so $\omega \leq \kappa$, and let α be least with $\kappa \leq \omega_\alpha$ (it exists since $\kappa \leq \omega_\kappa$). If $\alpha = 0$, then $\kappa = \omega$. If α is a limit and $\kappa < \omega_\alpha$, then $\kappa < \omega_\beta$ for some $\beta < \alpha$, contradicting minimality. If $\alpha = \beta + 1$ and $\kappa < \omega_\alpha = h(\omega_\beta)$, then κ injects into ω_β, so $\kappa \leq \omega_\beta \leq \kappa$ and $\kappa \approx \omega_\beta$ by Theorem 3.6.2; as both are cardinals, $\kappa = \omega_\beta$, contradicting the choice of α. □

Theorem 3.6.12 (Hessenberg)**.** *For every infinite cardinal κ, $\kappa \times \kappa \approx \kappa$.*

Proof. Order pairs of ordinals by $(\alpha, \beta) \lhd (\gamma, \delta)$ if $\max(\alpha, \beta) < \max(\gamma, \delta)$, or the maxima are equal and $\alpha < \gamma$, or the maxima are equal, $\alpha = \gamma$ and $\beta < \delta$. On every set of pairs this is a strict total order, and every nonempty set of pairs has a least element (minimize the maximum, then the first coordinate, then the second). For an ordinal κ, the set $\kappa \times \kappa$ contains, with any pair, all $\lhd$-smaller pairs.

Suppose the theorem fails and let κ be the least infinite cardinal with $\kappa \times \kappa \not\approx \kappa$. Let θ be the order type of $(\kappa \times \kappa, \lhd)$ (Theorem 3.5.10). If $\theta \leq \kappa$, then $\kappa \times \kappa \preceq \kappa$, and since $\kappa \preceq \kappa \times \kappa$ via $\xi \mapsto (\xi, 0)$, Theorem 3.6.2 gives a contradiction. So $\kappa < \theta$, and there is a pair $(\xi, \eta) \in \kappa \times \kappa$ whose set of $\lhd$-predecessors P has order type κ. Let $\delta = \max(\xi, \eta) + 1$. An infinite cardinal is a limit ordinal: for an infinite ordinal α, the map $\alpha + 1 \to \alpha$ sending α to 0, each $n \in \omega$ to $n + 1$, and fixing all other elements, is a bijection, so $\alpha + 1$ is not a cardinal. Hence $\delta < \kappa$, and $P \subseteq \delta \times \delta$. If δ is finite, so is $\delta \times \delta$, contradicting $P \approx \kappa$. Otherwise $\mu = |\delta|$ is an infinite cardinal with $\mu \leq \delta < \kappa$, and by minimality of κ, $\kappa \approx P \preceq \delta \times \delta \approx \mu \times \mu \approx \mu$. Then $\kappa \preceq \mu \leq \kappa$, so $\kappa \approx \mu$, contradicting that κ is a cardinal. □

Corollary 3.6.13. *$\omega \times \omega$ is countably infinite, and so is ω^n for every $n \geq 1$. The set of finite sequences of elements of a countable set is countable.*

Proof. The first statement is Theorem 3.6.12; fix a bijection $p : \omega \times \omega \to \omega$. By recursion on n define bijections $b_n : \omega^n \to \omega$ for $n \geq 1$ by $b_1(s) = s(0)$ and $b_{n+1}(s) = p(b_n(s|_n), s(n))$. It suffices to treat sequences of natural numbers, since an injection $X \to \omega$ induces an injection on sequences. The map sending a sequence s of length $n \geq 1$ to $p(n, b_n(s))$, and the empty sequence to $p(0, 0)$, is an injection into ω. □

3.7 The axiom of choice

Definition 3.7.1. A *choice function* for a set F of nonempty sets is a function $c : F \to \bigcup F$ with $c(X) \in X$ for all $X \in F$. The *axiom of choice* (AC) states that every set of nonempty sets has a choice function.

Theorem 3.7.2. *In ZF, the following statements are equivalent.*

1. *The axiom of choice.*
2. *(Well-ordering theorem) Every set admits a well-order.*
3. *(Zorn's lemma) Let $(P, \leq)$ be a partially ordered set in which every chain has an upper bound. Then P has a maximal element.*

Proof. (1) $\Rightarrow$ (2). Let A be a set and c a choice function for $\mathcal{P}(A) \setminus \{\emptyset\}$. Fix some $\star \notin A$. By transfinite recursion let $F(\alpha) = c(A \setminus F[\alpha])$ if $A \setminus F[\alpha] \neq \emptyset$, and $F(\alpha) = \star$ otherwise, where $F[\alpha] = \{F(\beta) : \beta < \alpha\}$. If $F(\beta) = \star$, then $A \subseteq F[\beta]$, so $F(\alpha) = \star$ for all $\alpha > \beta$. Hence if $F(\alpha) \neq \star$, all $F(\beta)$ with $\beta \leq \alpha$ lie in A, and $F(\alpha) \notin F[\alpha]$; so these values are distinct. If $F(\alpha) \neq \star$ for all $\alpha < h(A)$, then F would inject $h(A)$ into A, contradicting Theorem 3.6.9. So there is a least α with $F(\alpha) = \star$, and then $F|_\alpha \colon \alpha \to A$ is a bijection; transport the order of α.

(2) $\Rightarrow$ (1). Well-order $\bigcup F$ and let $c(X)$ be the least element of X.

(1) $\Rightarrow$ (3). Suppose P has no maximal element. Then every chain C has a *strict* upper bound: an upper bound u of C is not maximal, so there is $v > u$. Let c be a choice function for $\mathcal{P}(P) \setminus \{\emptyset\}$ and $\star \notin P$. Define by transfinite recursion $F(\alpha) = c(S_\alpha)$, where S_α is the set of strict upper bounds of $F[\alpha]$, if $F[\alpha] \subseteq P$ is a chain and S_α is nonempty, and $F(\alpha) = \star$ otherwise. By induction on α, $F[\alpha]$ is a chain in P on which F is strictly increasing: if this holds for all $\beta < \alpha$ then $F[\alpha]$ is a chain, so $S_\alpha \neq \emptyset$ and $F(\alpha)$ is greater than all $F(\beta)$, $\beta < \alpha$. Hence F injects $h(P)$ into P, contradicting Theorem 3.6.9.

(3) $\Rightarrow$ (1). Let F be a set of nonempty sets. Let P be the set of functions c with $\operatorname{dom}(c) \subseteq F$ and $c(X) \in X$ for all $X \in \operatorname{dom}(c)$, ordered by inclusion. The union of a chain in P is in P and is an upper bound. Let c be maximal. If $X \in F$ were not in the domain of c, choose $x \in X$; then $c \cup \{(X, x)\}$ would be larger. So c is a choice function for F. □

Remark 3.7.3. The well-ordering theorem was proved from the axiom of choice by Zermelo; see [Zer08]. Zorn's lemma is from [Zor35]. It is the form of choice used most often in algebra, for instance to show that every vector space has a basis or that every nonzero ring has a maximal ideal. Gödel showed that if ZF is consistent then so is ZFC [Gö38], and Cohen that the negation of AC is also consistent with ZF [Coh63]. From now on we work in ZFC.

Proposition 3.7.4. *Every set A has a cardinality $|A|$. For all sets, $A \approx B$ if and only if $|A| = |B|$, and $A \preceq B$ if and only if $|A| \leq |B|$. In particular any two sets are comparable: $A \preceq B$ or $B \preceq A$.*

Proof. By Theorem 3.7.2, every set can be well-ordered, so $|A|$ is defined. The first equivalence is clear. If $|A| \leq |B|$, then $|A| \subseteq |B|$ and $A \approx |A| \preceq |B| \approx B$. Conversely, if $A \preceq B$ and $|B| < |A|$, then $|A| \preceq |B| \subseteq |A|$ and Theorem 3.6.2 would give $|A| \approx |B|$, contradicting that $|A|$ is a cardinal. The last statement follows from Theorem 3.5.4. □

Proposition 3.7.5. *Let κ be an infinite cardinal and $(X_i)_{i \in I}$ a family with $|I| \leq \kappa$ and $|X_i| \leq \kappa$ for all i. Then $|\bigcup_{i \in I} X_i| \leq \kappa$. In particular a countable union of countable sets is countable.*

Proof. We may assume that all X_i are nonempty. By the axiom of choice there is a family $(g_i)_{i \in I}$ of surjections $g_i \colon \kappa \to X_i$ (choose one from each nonempty set of surjections). The map $(i, \xi) \mapsto g_i(\xi)$ is a surjection $q \colon I \times \kappa \to \bigcup_i X_i$. Since $I \times \kappa \preceq \kappa \times \kappa \approx \kappa$ by Theorem 3.6.12, there is an injection $j \colon I \times \kappa \to \kappa$. Sending $u \in \bigcup_i X_i$ to the least element of $j[q^{-1}[\{u\}]]$ is an injection $\bigcup_i X_i \to \kappa$, because the sets $q^{-1}[\{u\}]$ are nonempty and pairwise disjoint. □

Corollary 3.7.6. *If A and B are nonempty and at least one is infinite, then $|A \times B| = |A \sqcup B| = \max(|A|, |B|)$, where $A \sqcup B = (\{0\} \times A) \cup (\{1\} \times B)$.*

Proof. Let $\kappa = \max(|A|, |B|)$, an infinite cardinal, and say $|A| = \kappa$. By Proposition 3.7.4 and Theorem 3.6.12, $A \times B \preceq \kappa \times \kappa \approx \kappa$ and $A \sqcup B \preceq 2 \times \kappa \preceq \kappa \times \kappa \approx \kappa$. Conversely A injects into $A \sqcup B$, and into $A \times B$ via $a \mapsto (a, b_0)$ for a fixed $b_0 \in B$. Conclude with Theorem 3.6.2. □

Remark 3.7.7. We write 2^κ for $|\mathcal{P}(\kappa)|$; by Theorem 3.6.3, $2^\kappa > \kappa$. The *continuum hypothesis* (CH) asserts $2^{\aleph_0} = \aleph_1$. It is independent of ZFC: it can be neither proved [Coh63] nor refuted [Gö38]. In Chapter 4 we show $|\mathbb{R}| = 2^{\aleph_0}$.

Cantor's original formulation of the continuum hypothesis did not mention $\aleph_1$: he conjectured that every infinite set of real numbers is either countable or equinumerous with the whole line, that is, that there is no size strictly between that of $\mathbb{N}$ and that of $\mathbb{R}$. With the axiom of choice the two formulations are equivalent. Since $|\mathbb{R}| = 2^{\aleph_0} = |\mathcal{P}(\omega)|$ (Chapter 4), we state it for subsets of $\mathcal{P}(\omega)$.

Proposition 3.7.8. *The following are equivalent:*

1. $2^{\aleph_0} = \aleph_1$;
2. *there is no cardinal* κ *with* $\aleph_0 < \kappa < 2^{\aleph_0}$;
3. *every infinite subset of* $\mathcal{P}(\omega)$ *is either countable or equinumerous with* $\mathcal{P}(\omega)$.

Proof. First, $\aleph_1$ is the least cardinal larger than $\aleph_0$: by Proposition 3.6.11 an infinite cardinal κ is ω_α for a unique α, and $\kappa > \omega_0$ forces $\alpha \geq 1$, hence $\kappa \geq \omega_1$. Also $2^{\aleph_0} > \aleph_0$ by Theorem 3.6.3, so $2^{\aleph_0} \geq \aleph_1$.

(1)⇒(2): a cardinal $\kappa > \aleph_0$ satisfies $\kappa \geq \aleph_1 = 2^{\aleph_0}$.

(2)⇒(1): $\aleph_1$ is a cardinal with $\aleph_0 < \aleph_1 \leq 2^{\aleph_0}$; by (2) it is not strictly smaller than $2^{\aleph_0}$, so $\aleph_1 = 2^{\aleph_0}$.

(2)⇒(3): let $A \subseteq \mathcal{P}(\omega)$ be infinite. By Proposition 3.7.4, A has a cardinality $|A|$ with $|A| \leq 2^{\aleph_0}$, and $|A| \geq \aleph_0$, since an infinite cardinal is at least ω. If $|A| = \aleph_0$, A is countable; otherwise $\aleph_0 < |A| \leq 2^{\aleph_0}$, and by (2) $|A| = 2^{\aleph_0}$, that is, $A \approx \mathcal{P}(\omega)$.

(3)⇒(2): let $\aleph_0 < \kappa \leq 2^{\aleph_0}$. Then κ injects into $\mathcal{P}(\omega)$; its image A is an infinite subset with $|A| = \kappa > \aleph_0$, so it is not countable, and by (3) $\kappa = |A| = 2^{\aleph_0}$. □

Remark 3.7.9.

1. In terms of real numbers, (3) reads: *every uncountable set of real numbers can be put in bijection with* $\mathbb{R}$. Cantor proved this for closed sets, by showing that an uncountable closed set contains a nonempty perfect set (a closed set without isolated points), which has the cardinality of $\mathbb{R}$; the *Cantor–Bendixson theorem*. The same holds for Borel sets, and more generally for analytic sets (Alexandrov, Hausdorff, Suslin) [Jec03]. So no "reasonably definable" set of reals can be a counterexample to CH, and yet CH cannot be proved (Remark 3.7.7): a counterexample, if it exists, is a set that can only be produced by the axiom of choice.

2. The equivalence of (1) and (3) uses the axiom of choice, through Proposition 3.7.4: without it, a set of reals might be uncountable and still not comparable with $\aleph_1$, and the two formulations can come apart.

3. The *generalised continuum hypothesis* (GCH) asserts $2^{\aleph_\alpha} = \aleph_{\alpha+1}$ for all α; by the same argument it says that for every infinite cardinal κ there is no cardinal strictly between κ and 2^κ. It is also consistent with ZFC [Gö38], and so is its negation [Coh63].

Definition 3.7.10. Let α be a limit ordinal. A map $f : \beta \to \alpha$ is *cofinal* if its image is unbounded in α. The *cofinality* $\operatorname{cf}(\alpha)$ is the least ordinal β admitting a cofinal map $\beta \to \alpha$. An infinite cardinal κ is *regular* if $\operatorname{cf}(\kappa) = \kappa$, and *singular* otherwise.

Lemma 3.7.11. *Let* κ *be a regular cardinal and* $X \subseteq \kappa$ *a set with* $|X| < \kappa$. *Then* $\sup X < \kappa$.

Proof. Let $\mu = |X| < \kappa$ and let $f : \mu \to X$ be a bijection. If $\sup X = \kappa$, then f is a cofinal map $\mu \to \kappa$, so $\operatorname{cf}(\kappa) \leq \mu < \kappa$. □

Proposition 3.7.12. *The cardinal* ω *is regular, and every infinite successor cardinal* $\omega_{\alpha+1}$ *is regular.*

Proof. A map from a finite ordinal n to ω has a largest value, so it is not cofinal. Let $\kappa = \omega_{\alpha+1}$ and suppose $f : \beta \to \kappa$ is cofinal with $\beta < \kappa$. Then $|\beta| \leq \omega_\alpha$, every $f(\xi) < \kappa$ has $|f(\xi)| \leq \omega_\alpha$, and $\kappa = \bigcup_{\xi<\beta} f(\xi)$ because κ is a limit ordinal. By Proposition 3.7.5, $|\kappa| \leq \omega_\alpha$, a contradiction. □

Counterexample 3.7.13. Not every infinite cardinal is regular. The map $n \mapsto \omega_n$ is cofinal from ω to $\omega_\omega = \sup_n \omega_n$, so $\mathrm{cf}(\omega_\omega) = \omega < \omega_\omega$.

Definition 3.7.14. A cardinal κ is *strongly inaccessible* if it is uncountable, regular, and $2^\lambda < \kappa$ for every cardinal $\lambda < \kappa$.

3.8 Universes

Definition 3.8.1. A *Grothendieck universe* is a set $\mathcal{U}$ such that

1. if $x \in \mathcal{U}$ and $y \in x$, then $y \in \mathcal{U}$;
2. if $x, y \in \mathcal{U}$, then $\{x, y\} \in \mathcal{U}$;
3. if $x \in \mathcal{U}$, then $\mathcal{P}(x) \in \mathcal{U}$;
4. if $I \in \mathcal{U}$ and $(x_i)_{i\in I}$ is a family with $x_i \in \mathcal{U}$ for all i, then $\bigcup_{i\in I} x_i \in \mathcal{U}$.

This is the definition of [AGV72, Exposé I, Appendice].

Lemma 3.8.2. *Let $\mathcal{U}$ be a nonempty universe, $A, B, x, y \in \mathcal{U}$ and $I \in \mathcal{U}$.*

1. *$\emptyset \in \mathcal{U}$, and every subset of an element of $\mathcal{U}$ is in $\mathcal{U}$.*
2. *$\{x\}$, (x, y), $x \cup y$, $A \times B$ and B^A are in $\mathcal{U}$.*
3. *If $x_i \in \mathcal{U}$ for all $i \in I$, then $\prod_{i\in I} x_i \in \mathcal{U}$; and if $f : I \to \mathcal{U}$ is a map, the image $f[I]$ is in $\mathcal{U}$.*
4. *If $\sim$ is an equivalence relation on A, then $A/\sim \in \mathcal{U}$.*

Proof. (1) If $y \subseteq x \in \mathcal{U}$, then $y \in \mathcal{P}(x) \in \mathcal{U}$, so $y \in \mathcal{U}$. Taking any $x \in \mathcal{U}$ and $y = \emptyset$ gives $\emptyset \in \mathcal{U}$. (2) $\{x\} = \{x, x\}$ and $(x, y) = \{\{x\}, \{x, y\}\}$. Since $\{A, B\} \in \mathcal{U}$, the union of the family A, B indexed by it is $A \cup B \in \mathcal{U}$. Then $A \times B \subseteq \mathcal{P}(\mathcal{P}(A \cup B))$ and $B^A \subseteq \mathcal{P}(A \times B)$. (3) $\bigcup_i x_i \in \mathcal{U}$ and $\prod_i x_i \subseteq (\bigcup_i x_i)^I$. The image is $f[I] = \bigcup_{i\in I}\{f(i)\}$. (4) $A/\sim \subseteq \mathcal{P}(A)$. □

Theorem 3.8.3. *If κ is a strongly inaccessible cardinal, then V_κ is a Grothendieck universe and $\omega \in V_\kappa$.*

Proof. First, $|V_\alpha| < \kappa$ for all $\alpha < \kappa$, by transfinite induction: $V_0 = \emptyset$; $|V_{\alpha+1}| = 2^{|V_\alpha|} < \kappa$ by strong inaccessibility; and for a limit $\lambda < \kappa$, the cardinals $|V_\alpha|$, $\alpha < \lambda$, form a set of fewer than κ ordinals below κ, so their supremum μ is $< \kappa$ by Lemma 3.7.11, and $|V_\lambda| \leq \max(|\lambda|, \mu, \omega) < \kappa$ by Proposition 3.7.5.

Since κ is a limit ordinal (being an infinite cardinal), every $x \in V_\kappa$ lies in some $V_{\alpha+1}$ with $\alpha < \kappa$, so $x \subseteq V_\alpha$. We check the axioms. (1) holds because V_κ is transitive (Lemma 3.5.12). (2) If $x \subseteq V_\alpha$ and $y \subseteq V_\beta$ with $\alpha \leq \beta < \kappa$, then $x, y \in V_{\beta+1}$ and $\{x, y\} \in V_{\beta+2}$. (3) If $x \subseteq V_\alpha$ then $\mathcal{P}(x) \subseteq \mathcal{P}(V_\alpha) = V_{\alpha+1}$, so $\mathcal{P}(x) \in V_{\alpha+2}$. (4) Let $I \in V_\kappa$, so $|I| < \kappa$, and for $i \in I$ let $\alpha_i < \kappa$ be least with $x_i \subseteq V_{\alpha_i}$. The set $\{\alpha_i : i \in I\}$ has fewer than κ elements, so its supremum α is $< \kappa$ by Lemma 3.7.11. Then $\bigcup_i x_i \subseteq V_\alpha$, hence lies in $V_{\alpha+1}$. Finally, $\omega \subseteq V_\omega$, so $\omega \in V_{\omega+1}$, and $\omega + 1 < \kappa$ as κ is uncountable. □

Theorem 3.8.4. *A set $\mathcal{U}$ is a Grothendieck universe with $\omega \in \mathcal{U}$ if and only if $\mathcal{U} = V_\kappa$ for a strongly inaccessible cardinal κ.*

One direction is Theorem 3.8.3; for the other, see [AGV72, Exposé I, Appendice].

Remark 3.8.5. If κ is strongly inaccessible, the structure $(V_\kappa, \in)$ is a model of ZFC [Jec03, Chapter 12]. Hence ZFC cannot prove that a universe containing ω exists, if ZFC is consistent (Remark 2.8.10). Following [AGV72], we therefore add to ZFC the axiom that there is a Grothendieck universe containing ω, and we fix one, $\mathcal{U}$, as in Notation 1.7.1. Only this single universe is needed in this project.

Remark 3.8.6. A set is *small* if it is an element of $\mathcal{U}$. By Lemma 3.8.2, the small sets are closed under all the constructions of this chapter applied to small sets: subsets, pairs, products, sets of maps, quotients, power sets, and unions and products of families indexed by small sets. Since $\omega \in \mathcal{U}$, the number systems $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$ and $\mathbb{C}$ constructed in Chapter 4 are small, and so is every object built from them by these constructions. A set that is merely equinumerous with a small set need not be small (it may even fail to be a subset of $\mathcal{U}$), but it is in bijection with one, which is all that matters in practice.

3.9 Exercises

Exercise 3.9.1. Let A, B, C be sets. Show that $f \mapsto (a \mapsto (b \mapsto f(a,b)))$ is a bijection $C^{A\times B} \to (C^B)^A$, and that $(A \times B) \times C \approx A \times (B \times C)$.

Exercise 3.9.2. Show that the axiom of choice is equivalent (in ZF) to the statement that every surjection $f : A \to B$ has a *section*, that is, a map $s : B \to A$ with $f \circ s = \mathrm{id}_B$.

Solution. Given AC and a surjection f, choose $s(b)$ from the nonempty set $f^{-1}[\{b\}]$. Conversely, given a set F of nonempty sets, let $A = \{(X, x) : X \in F, x \in X\}$ and let $f : A \to F$ be the first projection, which is surjective. If s is a section, then $X \mapsto$ (second coordinate of $s(X)$) is a choice function. □

Exercise 3.9.3. Using the axiom of choice, show that every infinite set has a countably infinite subset.

Exercise 3.9.4. Show that an ordinal α is a limit ordinal if and only if $\alpha \neq 0$ and $\alpha = \bigcup \alpha$.

Exercise 3.9.5. Show that V_ω is a Grothendieck universe which does not contain ω, and that every element of V_ω is a finite set. Show that $\emptyset$ is also a universe. (So the condition $\omega \in \mathcal{U}$ in Remark 3.8.5 is not automatic.)

Exercise 3.9.6. Show that ω^ω (the set of maps $\omega \to \omega$) and $\mathcal{P}(\omega)$ are equinumerous.

Exercise 3.9.7. Show that for every set A of sets there is a set not equinumerous with a subset of any element of A. Deduce that the class of all cardinals is not a set.

Chapter 4

Number Systems

4.1 Introduction

Starting from the natural numbers of Chapter 3, we construct the integers, the rational numbers, the real numbers and the complex numbers, and establish the properties used everywhere else: the laws of arithmetic, unique factorisation of integers, the least upper bound property of $\mathbb{R}$ and its uniqueness, and the basic properties of $\mathbb{C}$. Along the way we introduce the vocabulary of commutative rings, fields and ordered fields; general rings are studied in Chapter 8.

Classical references are [Lan30], which carries out these constructions in full detail, [Ded72] for the real numbers, and [Rud76, Chapter 1].

Prerequisites. Chapter 3 (Set Theory).

On the way to the Hodge conjecture. A reader who knows the integers, the rationals, the real and the complex numbers can skim this chapter; later chapters use mainly divisibility and prime factorisation (Section 4.5) and the characterisation of $\mathbb{R}$ as the complete ordered field (Section 4.7).

4.2 Arithmetic of the natural numbers

Recall from Example 3.4.7 that addition and multiplication on $\mathbb{N} = \omega$ are defined by $m+0 = m$, $m + S(n) = S(m + n)$, $m \cdot 0 = 0$ and $m \cdot S(n) = m \cdot n + m$. We have $m + 1 = S(m)$, since $m + S(0) = S(m + 0)$. All inductions below are instances of Theorem 3.4.2.

Proposition 4.2.1. *For all $m, n, k \in \mathbb{N}$:*

1. $(m + n) + k = m + (n + k)$;
2. $m + n = n + m$;
3. *if $m + k = n + k$, then $m = n$;*
4. *if $m + n = 0$, then $m = n = 0$.*

Proof. (1) By induction on k: for $k = 0$ both sides are $m+n$, and $(m+n)+S(k) = S((m+n)+k) = S(m + (n + k)) = m + S(n + k) = m + (n + S(k))$.

(2) First, $0 + n = n$ by induction on n. Next, $S(m) + n = S(m + n)$ by induction on n: $S(m) + 0 = S(m) = S(m + 0)$ and $S(m) + S(n) = S(S(m) + n) = S(S(m + n)) = S(m + S(n))$. Now induct on n: $m + 0 = m = 0 + m$, and $m + S(n) = S(m + n) = S(n + m) = S(n) + m$.

(3) By induction on k, using that S is injective (Proposition 3.4.5): $m + S(k) = n + S(k)$ means $S(m + k) = S(n + k)$.

(4) If $n = S(n')$ then $m + n = S(m + n') \neq 0$. So $n = 0$, and then $m = 0$. □

Proposition 4.2.2. *For all $m, n, k \in \mathbb{N}$:*

1. $m \cdot (n + k) = m \cdot n + m \cdot k$;
2. $(m \cdot n) \cdot k = m \cdot (n \cdot k)$;
3. $m \cdot n = n \cdot m$ *and* $1 \cdot n = n$;
4. *if* $m \cdot n = 0$, *then* $m = 0$ *or* $n = 0$.

Proof. (1) By induction on k: $m(n + 0) = mn = mn + 0$, and $m(n + S(k)) = m \cdot S(n + k) = m(n + k) + m = (mn + mk) + m = mn + m \cdot S(k)$.

(2) By induction on k: $(mn) \cdot 0 = 0 = m(n \cdot 0)$, and, using (1), $(mn) \cdot S(k) = (mn)k + mn = m(nk) + mn = m(nk + n) = m(n \cdot S(k))$.

(3) By induction, $0 \cdot n = 0$ and $S(m) \cdot n = mn + n$; for the second, $S(m) \cdot S(n) = S(m)n + S(m) = (mn + n) + S(m)$ and $m \cdot S(n) + S(n) = (mn + m) + S(n)$, and both equal $S(mn + m + n)$ by Proposition 4.2.1. Then $mn = nm$ follows by induction on n, and $1 \cdot n = 0 \cdot n + n = n$.

(4) If $m = S(m')$ and $n = S(n')$, then $mn = mn' + m = S(mn' + m')$, which is not 0. □

Proposition 4.2.3. *For $m, n \in \mathbb{N}$, the following are equivalent: $m \leq n$ in the order of ordinals (Proposition 3.5.7); there is $k \in \mathbb{N}$ with $m + k = n$. This k is unique. Moreover, for all $m, n, k \in \mathbb{N}$: if $m \leq n$ then $m + k \leq n + k$ and $mk \leq nk$; and if $mk = nk$ with $k \neq 0$ then $m = n$.*

Proof. By induction on k, $m \leq m + k$: indeed $m + S(k) = S(m + k)$ contains $m + k$. Conversely we show by induction on n that $m \leq n$ implies $m + k = n$ for some k. For $n = 0$, $m = 0$ and $k = 0$. If $m \leq S(n)$, then $m = S(n)$ (take $k = 0$) or $m \leq n$, in which case $m + k = n$ for some k and $m + S(k) = S(n)$. Uniqueness of k is Proposition 4.2.1(3).

If $m + j = n$, then $(m + k) + j = n + k$ and $mk + jk = nk$, which gives the monotonicity statements. If $mk = nk$ with $k \neq 0$ and, say, $m < n$, write $n = m + j$ with $j \neq 0$; then $mk + jk = mk + 0$, so $jk = 0$, contradicting Proposition 4.2.2(4). □

Proposition 4.2.4 (Division with remainder)**.** *Let $m, n \in \mathbb{N}$ with $n \geq 1$. There are unique $q, r \in \mathbb{N}$ with $m = qn + r$ and $r < n$.*

Proof. Existence, by induction on m: for $m = 0$ take $q = r = 0$. If $m = qn + r$ with $r < n$, then $m + 1 = qn + (r + 1)$, and either $r + 1 < n$, or $r + 1 = n$ and $m + 1 = (q + 1)n + 0$. Uniqueness: if $qn + r = q'n + r'$ with $r, r' < n$ and $q < q'$, then $q'n + r' \geq (q + 1)n = qn + n > qn + r$, a contradiction; so $q = q'$, and $r = r'$ by cancellation. □

4.3 Commutative rings and fields

Definition 4.3.1. A *commutative ring* is a set R with elements $0, 1 \in R$ and maps $+, \cdot : R \times R \to R$, the *addition* $(a, b) \mapsto a + b$ and the *multiplication* $(a, b) \mapsto a \cdot b$, usually written ab, such that for all $a, b, c \in R$: $(a + b) + c = a + (b + c)$; $a + b = b + a$; $a + 0 = a$; there is $a' \in R$ with $a + a' = 0$; $(ab)c = a(bc)$; $ab = ba$; $1 \cdot a = a$; and $a(b + c) = ab + ac$. A *homomorphism* of commutative rings is a map f with $f(a + b) = f(a) + f(b)$, $f(ab) = f(a)f(b)$ and $f(1) = 1$. A commutative ring is an *integral domain* if $1 \neq 0$ and $ab = 0$ implies $a = 0$ or $b = 0$; it is a *field* if $1 \neq 0$ and every $a \neq 0$ has an element a^{-1} with $aa^{-1} = 1$.

Lemma 4.3.2. *In a commutative ring R: the element a' with $a + a' = 0$ is unique, and we write it $-a$; $0 \cdot a = 0$; $(-a)b = -(ab)$; $(-a)(-b) = ab$. A field is an integral domain, and in a field a^{-1} is unique.*

Proof. If $a + a' = 0 = a + a''$, then $a' = a' + (a + a'') = (a' + a) + a'' = a''$. Next $0 \cdot a = (0 + 0)a = 0 \cdot a + 0 \cdot a$, and adding $-(0 \cdot a)$ gives $0 \cdot a = 0$. Then $ab + (-a)b = (a + (-a))b = 0$, so $(-a)b = -(ab)$, and $(-a)(-b) = -(a(-b)) = -(-(ab)) = ab$. In a field, if $ab = 0$ and $a \neq 0$ then $b = a^{-1}ab = 0$. Uniqueness of inverses is proved like uniqueness of $-a$. □

Definition 4.3.3. An *ordered ring* is a commutative ring R with a total order $\leq$ such that $a \leq b$ implies $a + c \leq b + c$, and $0 \leq a$, $0 \leq b$ imply $0 \leq ab$. An *ordered field* is an ordered ring that is a field. An element a is *positive* if $a > 0$. The *absolute value* is $|a| = a$ if $a \geq 0$ and $|a| = -a$ otherwise.

Lemma 4.3.4. *Let R be an ordered ring with $1 \neq 0$ and $a, b, c \in R$.*

1. *$a < b$ if and only if $-b < -a$; and $a^2 \geq 0$, so $1 > 0$.*
2. *If $a \leq b$ and $c \geq 0$, then $ac \leq bc$.*
3. *$|ab| = |a||b|$ and $|a + b| \leq |a| + |b|$.*
4. *The elements $n \cdot 1 = 1 + \cdots + 1$ (n summands) are positive for $n \geq 1$; in particular they are pairwise distinct.*
5. *If R is a field and $0 < a < b$, then $0 < b^{-1} < a^{-1}$.*

Proof. (1) Add $-a - b$ to $a < b$. If $a \geq 0$ then $a^2 \geq 0$; if $a < 0$ then $-a > 0$ and $a^2 = (-a)(-a) \geq 0$. Then $1 = 1^2 \geq 0$ and $1 \neq 0$. (2) $b - a \geq 0$, so $(b - a)c \geq 0$. (3) Both sides of the first equation are $\pm ab$ with the sign making them non-negative. For the second, $-|a| \leq a \leq |a|$ and similarly for b, so $-(|a| + |b|) \leq a + b \leq |a| + |b|$. (4) By induction, $(n + 1) \cdot 1 = n \cdot 1 + 1 > n \cdot 1$. (5) $a^{-1} = a(a^{-1})^2 \geq 0$ and $a^{-1} \neq 0$; similarly $b^{-1} > 0$. Multiplying $a < b$ by $a^{-1}b^{-1} > 0$ gives $b^{-1} < a^{-1}$. □

4.4 The integers

Definition 4.4.1. On $\mathbb{N} \times \mathbb{N}$ let $(a, b) \sim (c, d)$ if $a + d = b + c$. This is an equivalence relation (transitivity: from $a + d = b + c$ and $c + f = d + e$ we get $a + f + (c + d) = b + e + (c + d)$, and we cancel). The set of *integers* is $\mathbb{Z} = (\mathbb{N} \times \mathbb{N})/\sim$; we write $[a, b]$ for the class of (a, b). Define

$$[a, b] + [c, d] = [a + c, b + d], \qquad [a, b] \cdot [c, d] = [ac + bd, ad + bc],$$

$0 = [0, 0]$, $1 = [1, 0]$, and $[a, b] \leq [c, d]$ if $a + d \leq b + c$.

Theorem 4.4.2. *The operations and the order on $\mathbb{Z}$ are well defined, and make $\mathbb{Z}$ an ordered integral domain. The map $\iota\colon \mathbb{N} \to \mathbb{Z}$, $n \mapsto [n, 0]$, is injective and preserves 0, 1, addition, multiplication and order. Every integer is of the form $\iota(n)$ or $-\iota(n)$ with $n \in \mathbb{N}$. Every nonempty set of integers that is bounded below has a least element.*

Proof. If $(a, b) \sim (a', b')$, that is, $a + b' = b + a'$, then $(a + c) + (b' + d) = (b + d) + (a' + c)$, so addition is well defined. For multiplication, multiplying $a + b' = b + a'$ by c and $b + a' = a + b'$ by d and adding gives $ac + bd + a'd + b'c = ad + bc + a'c + b'd$, which says $(ac + bd, ad + bc) \sim (a'c + b'd, a'd + b'c)$; by symmetry of the formula the same holds in the second argument. For the order, $a + d \leq b + c$ and $a + b' = b + a'$ give $a' + d + (a + b') \leq b' + c + (a + b')$, and we cancel.

The ring axioms reduce to identities in $\mathbb{N}$. For instance, $[b, a]$ is an additive inverse of $[a, b]$, and distributivity follows from $[a, b]([c, d] + [e, f]) = [a(c + e) + b(d + f), a(d + f) + b(c + e)]$,

whose entries are those of $[ac+bd, ad+bc]+[ae+bf, af+be]$ by Propositions 4.2.1 and 4.2.2. The other axioms are verified in the same way.

If $a \geq b$, write $a = b + n$; then $[a, b] = [n, 0]$. If $a < b$, then $[a, b] = [0, n] = -[n, 0]$ with $b = a + n$. So every integer is $\iota(n)$ or $-\iota(n)$. The map ι preserves the operations, and $[m, 0] \leq [n, 0]$ if and only if $m \leq n$, so it is injective. The relation $\leq$ is a total order because $\leq$ is one on $\mathbb{N}$. It is compatible with addition, and if $x, y \geq 0$ then $x = \iota(m)$, $y = \iota(n)$ and $xy = \iota(mn) \geq 0$. If $xy = 0$ with $x = \pm\iota(m)$, $y = \pm\iota(n)$, then $\iota(mn) = 0$, so $m = 0$ or $n = 0$.

Finally, if $X \subseteq \mathbb{Z}$ is nonempty and bounded below by c, then $\{x - c : x \in X\}$ is a nonempty subset of $\iota(\mathbb{N})$, which has a least element by Proposition 3.5.7. □

Notation 4.4.3. We identify $n \in \mathbb{N}$ with $\iota(n) \in \mathbb{Z}$, so that $\mathbb{N} \subseteq \mathbb{Z}$. For a commutative ring R, $n \in \mathbb{N}$ and $a \in R$, we write na for $a + \cdots + a$ (n summands) and $(-n)a = -(na)$.

4.5 Divisibility and prime numbers

Definition 4.5.1. Let $a, b \in \mathbb{Z}$. We say *a divides b*, written $a \mid b$, if $b = ac$ for some $c \in \mathbb{Z}$. An integer $p \geq 2$ is *prime* if its only positive divisors are 1 and p. A *greatest common divisor* of a and b, not both zero, is a positive common divisor d divisible by every common divisor.

Theorem 4.5.2 (Division with remainder)**.** *Let $a, b \in \mathbb{Z}$ with $b \neq 0$. There are unique $q, r \in \mathbb{Z}$ with $a = qb + r$ and $0 \leq r < |b|$.*

Proof. Uniqueness: if $qb + r = q'b + r'$ then $(q - q')b = r' - r$ and $|r' - r| < |b|$, so $q = q'$ and $r = r'$. Existence: the set $\{a - kb : k \in \mathbb{Z}\} \cap \mathbb{N}$ is nonempty (take $k = -|a|$ if $b > 0$ and $k = |a|$ if $b < 0$, for which $a - kb = a + |a||b| \geq 0$), so it has a least element $r = a - qb$. If $r \geq |b|$, then $r - |b| = a - (q \pm 1)b$ is a smaller element. □

Theorem 4.5.3 (Bézout)**.** *Let $a, b \in \mathbb{Z}$ be not both zero, and let d be the least positive element of $\{ax + by : x, y \in \mathbb{Z}\}$. Then d is a greatest common divisor of a and b, and it is the only one. We write $d = \gcd(a, b)$.*

Proof. The set contains $a^2 + b^2 > 0$, so d exists; write $d = ax_0 + by_0$. Divide: $a = qd + r$ with $0 \leq r < d$. Then $r = a(1 - qx_0) + b(-qy_0)$ lies in the set, so $r = 0$ by minimality, and $d \mid a$; similarly $d \mid b$. Every common divisor of a and b divides $ax_0 + by_0 = d$. If d' is another greatest common divisor, then $d \mid d'$ and $d' \mid d$, and both are positive, so $d = d'$. □

Lemma 4.5.4 (Euclid)**.** *Let p be prime and $a, b \in \mathbb{Z}$. If $p \mid ab$, then $p \mid a$ or $p \mid b$.*

Proof. If $p \nmid a$, then $\gcd(p, a) = 1$, since it is a positive divisor of p different from p. By Theorem 4.5.3, $1 = px + ay$, so $b = pbx + aby$ is divisible by p. □

Theorem 4.5.5 (Fundamental theorem of arithmetic)**.** *Every integer $n \geq 2$ is a product $n = p_1 p_2 \cdots p_k$ of primes, and if $n = q_1 \cdots q_l$ is another such product, then $k = l$ and the q_j are a permutation of the p_i.*

Proof. Existence: if some $n \geq 2$ is not a product of primes, take the least such n. It is not prime, so $n = ab$ with $2 \leq a, b < n$, and a, b are products of primes, hence so is n. Uniqueness, by induction on k: p_k divides $q_1 \cdots q_l$, so by Lemma 4.5.4 (and induction on l) it divides some q_j, and then $p_k = q_j$ since q_j is prime. Cancelling gives two factorisations of n/p_k and the induction hypothesis applies (if $k = 1$, then $n = p_1$ is prime and $l = 1$). □

Theorem 4.5.6 (Euclid)**.** *There are infinitely many prime numbers.*

Proof. Let $p_1, \dots, p_k$ be primes and $N = p_1 \cdots p_k + 1 \geq 2$. By Theorem 4.5.5, some prime p divides N. If $p = p_i$, then p divides $N - p_1 \cdots p_k = 1$, which is impossible. So no finite set of primes contains all primes. □

Example 4.5.7. Repeated division with remainder computes greatest common divisors, since $\gcd(a,b) = \gcd(b,r)$ when $a = qb + r$. For $a = 252$, $b = 198$: $252 = 1 \cdot 198 + 54$, $198 = 3 \cdot 54 + 36$, $54 = 1 \cdot 36 + 18$, $36 = 2 \cdot 18$. So $\gcd(252, 198) = 18$, and going backwards, $18 = 54 - 36 = 4 \cdot 54 - 198 = 4 \cdot 252 - 5 \cdot 198$.

Remark 4.5.8. Unique factorisation is a special property of $\mathbb{Z}$. In the ring $\mathbb{Z}[\sqrt{-5}] = \{a + b\sqrt{-5} : a, b \in \mathbb{Z}\}$ one has $6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$, and none of these four factors can be written as a product of two non-units. Such phenomena are studied in Chapters 8 and 14.

4.6 The rational numbers

Definition 4.6.1. Let $P = \{(a,b) \in \mathbb{Z} \times \mathbb{Z} : b > 0\}$ and $(a,b) \sim (c,d)$ if $ad = bc$. This is an equivalence relation (for transitivity, $ad = bc$ and $cf = de$ give $adf = bcf = bde$, and we cancel $d \neq 0$ in the integral domain $\mathbb{Z}$). The set of *rational numbers* is $\mathbb{Q} = P/\!\sim$, and a/b denotes the class of (a,b). Define

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}, \qquad \frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd}, \qquad \frac{a}{b} \leq \frac{c}{d} \iff ad \leq bc.$$

Theorem 4.6.2. *The operations and the order on $\mathbb{Q}$ are well defined and make $\mathbb{Q}$ an ordered field. The map $\mathbb{Z} \to \mathbb{Q}$, $a \mapsto a/1$, is an injective ring homomorphism preserving the order, and $\mathbb{Q}$ is* Archimedean*: for every $x \in \mathbb{Q}$ there is $n \in \mathbb{N}$ with $x < n$.*

Proof. Well-definedness: if $ab' = a'b$, then $(ad + bc)(b'd) = (a'd + b'c)(bd)$ and $(ac)(b'd) = (a'c)(bd)$, and $ad \leq bc$ is equivalent to $ab'd \leq bb'c$ (multiply by $b' > 0$), that is to $a'bd \leq bb'c$, that is to $a'd \leq b'c$ (cancel $b > 0$). The field axioms are identities in $\mathbb{Z}$ as in Theorem 4.4.2; the zero is $0/1$, the unit $1/1$, $-(a/b) = (-a)/b$, and for $a \neq 0$ the inverse of a/b is b/a if $a > 0$ and $(-b)/(-a)$ if $a < 0$. The order is total, and compatible with the operations: $a/b \geq 0$ means $a \geq 0$, and a product or sum of such fractions again has non-negative numerator. The map $a \mapsto a/1$ is clearly an injective order-preserving homomorphism. Finally, for $x = a/b$ we have $x \leq |a| < |a| + 1$ because $b \geq 1$. □

Proposition 4.6.3. *Let K be an ordered field. There is a unique ring homomorphism $\mathbb{Q} \to K$; it is injective and order-preserving. We use it to regard $\mathbb{Q}$ as a subfield of K.*

Proof. By Lemma 4.3.4(4) the map $\mathbb{N} \to K$, $n \mapsto n \cdot 1$, is injective, and it preserves sums and products (by induction). Extend it to $\mathbb{Z}$ by $-n \mapsto -(n \cdot 1)$; this is an injective order-preserving ring homomorphism j. Define $f(a/b) = j(a)j(b)^{-1}$; this is well defined since $ad = bc$ gives $j(a)j(d) = j(b)j(c)$, and it is a ring homomorphism by the formulas of Definition 4.6.1. It preserves order: for $b, d > 0$, $a/b \leq c/d$ iff $ad \leq bc$ iff $j(a)j(d) \leq j(b)j(c)$ iff $j(a)j(b)^{-1} \leq j(c)j(d)^{-1}$, by Lemma 4.3.4(5). Hence it is injective. Uniqueness: a ring homomorphism g satisfies $g(1) = 1$, hence $g(n) = n \cdot 1$ and $g(-n) = -g(n)$, and $g(b)g(a/b) = g(a)$, so $g(a/b) = j(a)j(b)^{-1}$. □

Proposition 4.6.4. *There is no $x \in \mathbb{Q}$ with $x^2 = 2$.*

Proof. Suppose $(a/b)^2 = 2$ with $a, b > 0$, so $a^2 = 2b^2$. In the factorisations of Theorem 4.5.5, the prime 2 occurs an even number of times in a^2 and an odd number of times in $2b^2$, contradicting uniqueness. □

Counterexample 4.6.5. The set $A = \{x \in \mathbb{Q} : x \le 0 \text{ or } x^2 < 2\}$ is nonempty and bounded above (by 2), but has no least upper bound in $\mathbb{Q}$. Indeed, for $p \in \mathbb{Q}$ with $p > 0$ put $q = p - \frac{p^2-2}{p+2} = \frac{2p+2}{p+2}$; then $q^2 - 2 = \frac{2(p^2-2)}{(p+2)^2}$. If $p \in A$ and $p > 0$, then $p^2 < 2$, so $q > p$ and $q^2 < 2$: A has no largest element. If $p > 0$ is an upper bound of A, then $p^2 > 2$ by Proposition 4.6.4 (and $p^2 < 2$ is impossible since then $p \in A$ is largest), so $q < p$ and $q^2 > 2$, and q is a smaller upper bound. Hence no upper bound is least.

4.7 Complete ordered fields

Definition 4.7.1. An ordered field K is *complete* if every nonempty subset of K that is bounded above has a least upper bound (supremum) in K. It is *Archimedean* if for every $x \in K$ there is $n \in \mathbb{N}$ with $x < n$.

Lemma 4.7.2. *In a complete ordered field every nonempty subset bounded below has a greatest lower bound (infimum), namely* $\inf A = -\sup(-A)$. *If A, B are nonempty and bounded above, then* $\sup(A + B) = \sup A + \sup B$, *where* $A + B = \{a + b : a \in A, b \in B\}$; *if moreover A and B consist of positive elements, then* $\sup(AB) = \sup A \cdot \sup B$.

Proof. The first claim is clear since $x \mapsto -x$ reverses the order. Let $s = \sup A$, $t = \sup B$. Clearly $s + t$ is an upper bound of $A + B$. If $u < s + t$, then $u - t < s$, so there is $a \in A$ with $a > u - t$; then $u - a < t$ and there is $b \in B$ with $b > u - a$, so $a + b > u$. For products, st is an upper bound of AB by Lemma 4.3.4(2). If $0 < u < st$, then $u/t < s$, so some $a \in A$ has $a > u/t$, and then $u/a < t$ and some $b \in B$ has $b > u/a$, so $ab > u$. Upper bounds $u \le 0$ are not smaller than $st > 0$. □

Proposition 4.7.3. *A complete ordered field is Archimedean. In an Archimedean ordered field, $\mathbb{Q}$ is* dense*: for all $x < y$ there is $q \in \mathbb{Q}$ with $x < q < y$.*

Proof. If $\mathbb{N} \subseteq K$ were bounded above, let $s = \sup \mathbb{N}$. Then $s - 1$ is not an upper bound, so $n > s - 1$ for some $n \in \mathbb{N}$, and $n + 1 > s$; contradiction.

Let K be Archimedean and $x < y$. Choose $n \in \mathbb{N}$ with $n > (y - x)^{-1}$, so $ny > nx + 1$. The set of integers m with $m > nx$ is nonempty and bounded below (both by the Archimedean property applied to $\pm nx$), so it has a least element m by Theorem 4.4.2. Then $m - 1 \le nx$, so $nx < m \le nx + 1 < ny$, and $q = m/n$ works. □

Proposition 4.7.4. *Let K be a complete ordered field, $x \in K$ with $x \ge 0$, and $n \ge 1$. There is a unique $y \in K$ with $y \ge 0$ and $y^n = x$. We write $y = \sqrt[n]{x}$, or $\sqrt{x}$ if $n = 2$. In particular the non-negative elements of K are exactly the squares.*

Proof. Uniqueness: if $0 \le y_1 < y_2$ then $y_1^n < y_2^n$. For existence we may assume $x > 0$ and $n \ge 2$ (for $n = 1$ take $y = x$). For $0 < a < b$ we have $b^n - a^n = (b-a)(b^{n-1} + b^{n-2}a + \cdots + a^{n-1}) < (b - a)nb^{n-1}$. Let $E = \{t \in K : t \ge 0, t^n < x\}$. It contains 0, and is bounded above by $1 + x$ (if $t > 1 + x$ then $t^n \ge t > x$). Let $y = \sup E$; then $y > 0$, since $t = x/(1 + x)$ lies in E.

Suppose $y^n < x$. Choose h with $0 < h < 1$ and $h < (x - y^n)/(n(y + 1)^{n-1})$. Then $(y + h)^n - y^n < hn(y + h)^{n-1} < hn(y + 1)^{n-1} < x - y^n$, so $y + h \in E$, contradicting that y is an upper bound.

Suppose $y^n > x$. Let $k = (y^n - x)/(ny^{n-1})$; then $0 < k < y$. For $t \ge y - k$ we have $y^n - t^n \le y^n - (y - k)^n < kny^{n-1} = y^n - x$, so $t^n > x$ and $t \notin E$. Hence $y - k$ is an upper bound of E, contradicting that y is least. So $y^n = x$. □

Definition 4.7.5. Let K be an ordered field. A sequence $(x_n)_{n\in\mathbb{N}}$ in K *converges* to $x \in K$ if for every $\varepsilon > 0$ in K there is N with $|x_n - x| < \varepsilon$ for all $n \geq N$. It is a *Cauchy sequence* if for every $\varepsilon > 0$ there is N with $|x_n - x_m| < \varepsilon$ for all $m, n \geq N$.

Proposition 4.7.6. *In a complete ordered field every Cauchy sequence converges.*

Proof. Let (x_n) be Cauchy. Choosing N for $\varepsilon = 1$, all terms lie between $\min(x_0, \dots, x_N) - 1$ and $\max(x_0, \dots, x_N) + 1$, so the sequence is bounded. Let $s_n = \sup\{x_k : k \geq n\}$; this sequence is decreasing and bounded below, and we let $x = \inf_n s_n$. Given $\varepsilon > 0$, choose N with $|x_n - x_m| < \varepsilon$ for $m, n \geq N$. For $n \geq N$, every x_k with $k \geq n$ lies in $(x_n - \varepsilon, x_n + \varepsilon)$, so $x_n - \varepsilon \leq s_m \leq x_n + \varepsilon$ for all $m \geq n$; since the s_m decrease, $x = \inf_{m\geq n} s_m$ lies in $[x_n - \varepsilon, x_n + \varepsilon]$. Hence $|x_n - x| \leq \varepsilon$ for $n \geq N$. □

Theorem 4.7.7. *Let K and L be complete ordered fields. There is exactly one ring homomorphism $K \to L$, and it is an order-preserving isomorphism of fields.*

Proof. Regard $\mathbb{Q} \subseteq K$ and $\mathbb{Q} \subseteq L$ by Proposition 4.6.3. For $x \in K$ let $D(x) = \{q \in \mathbb{Q} : q < x\}$, which is nonempty and bounded above in $\mathbb{Q}$ by Proposition 4.7.3. Define $\varphi(x) = \sup_L D(x)$.

By density, $x = \sup_K D(x)$, and $x < y$ implies that $D(x) \subsetneq D(y)$ contains two rationals between x and y, so $\varphi(x) < \varphi(y)$. For $q \in \mathbb{Q}$, $\varphi(q) = q$. Every $y \in L$ is in the image: with $D_L(y) = \{q : q < y\}$ and $x = \sup_K D_L(y)$ we get $D(x) = D_L(y)$ by density in both fields, so $\varphi(x) = y$. So φ is an order-preserving bijection.

By density, $D(x + y) = D(x) + D(y)$, so Lemma 4.7.2 gives $\varphi(x + y) = \varphi(x) + \varphi(y)$. For $x, y > 0$, the positive elements of $D(xy)$ are the products of positive elements of $D(x)$ and $D(y)$, so $\varphi(xy) = \varphi(x)\varphi(y)$. Since $\varphi(-x) = -\varphi(x)$ (from additivity) and $\varphi(0) = 0$, multiplicativity follows for all signs. Hence φ is an isomorphism.

Let $\psi\colon K \to L$ be any ring homomorphism. By Proposition 4.7.4, $x \geq 0$ implies $x = y^2$ and so $\psi(x) = \psi(y)^2 \geq 0$; hence ψ is order-preserving. Also ψ is the identity on $\mathbb{Q}$ by Proposition 4.6.3. For $q \in D(x)$ we get $q = \psi(q) \leq \psi(x)$, so $\varphi(x) \leq \psi(x)$; applying this to $-x$ gives $\varphi(x) \geq \psi(x)$. So $\psi = \varphi$. □

4.8 The real numbers

Definition 4.8.1. Let C be the set of Cauchy sequences in $\mathbb{Q}$ and $\mathcal{N} \subseteq C$ the set of sequences converging to 0. For $x, y \in C$ write $x \sim y$ if $x - y \in \mathcal{N}$. The set of *real numbers* is $\mathbb{R} = C/{\sim}$. Operations are defined termwise: $[x] + [y] = [(x_n + y_n)_n]$ and $[x] \cdot [y] = [(x_n y_n)_n]$. A real number $[x]$ is *positive* if there are $\varepsilon \in \mathbb{Q}$, $\varepsilon > 0$, and N with $x_n > \varepsilon$ for all $n \geq N$, and $[x] < [y]$ means that $[y] - [x]$ is positive. A rational number q is identified with the class of the constant sequence $(q)_n$.

Lemma 4.8.2. 1. *Every $x \in C$ is bounded, and C is closed under termwise sums and products.*

2. *$\mathcal{N}$ is closed under sums, and $xz \in \mathcal{N}$ for $x \in C$ and $z \in \mathcal{N}$. In particular $\sim$ is an equivalence relation compatible with sums and products.*

3. *If $x \in C \setminus \mathcal{N}$, there are a rational $\varepsilon > 0$ and N such that either $x_n > \varepsilon$ for all $n \geq N$, or $x_n < -\varepsilon$ for all $n \geq N$.*

Proof. (1) Boundedness is proved as in Proposition 4.7.6. If $|x_n|, |y_n| \leq M$, then $|x_n y_n - x_m y_m| \leq M|y_n - y_m| + M|x_n - x_m|$, and similarly for sums. (2) If $|x_n| \leq M$ and $z \to 0$, then $|x_n z_n| \leq M|z_n| \to 0$. Sums are similar. If $x \sim x'$ and $y \sim y'$, then $xy - x'y' = x(y - y') + y'(x - x') \in \mathcal{N}$. (3) Since $x \notin \mathcal{N}$, there is a rational $\delta > 0$ such that $|x_n| \geq \delta$ for infinitely many n. Choose N with $|x_n - x_m| < \delta/2$ for $m, n \geq N$, and $m \geq N$ with $|x_m| \geq \delta$. If $x_m \geq \delta$ then $x_n > \delta/2$ for all $n \geq N$; if $x_m \leq -\delta$ then $x_n < -\delta/2$ for all $n \geq N$. Take $\varepsilon = \delta/2$. □

Theorem 4.8.3. *$\mathbb{R}$ is a complete ordered field, and $\mathbb{Q} \to \mathbb{R}$ is an injective order-preserving ring homomorphism. By Theorem 4.7.7, $\mathbb{R}$ is the unique complete ordered field up to unique isomorphism.*

Proof. By Lemma 4.8.2, the operations are well defined, and the ring axioms hold termwise. If $[x] \neq 0$, then by part (3) of the lemma there is N with $|x_n| > \varepsilon$ for $n \geq N$. Let $y_n = x_n^{-1}$ for $n \geq N$ and $y_n = 0$ otherwise; since $|y_n - y_m| = |x_m - x_n|/|x_n x_m| \leq \varepsilon^{-2}|x_m - x_n|$ for $m, n \geq N$, y is Cauchy, and $xy - 1$ is eventually 0. So $\mathbb{R}$ is a field.

Positivity is well defined: if $x_n > \varepsilon$ for $n \geq N$ and $z \in \mathcal{N}$, then $x_n + z_n > \varepsilon/2$ for large n. By part (3), every nonzero real number is either positive or its negative is positive, and not both; sums and products of positive numbers are positive. It follows that $<$ is a strict total order compatible with the ring operations, so $\mathbb{R}$ is an ordered field. The embedding of $\mathbb{Q}$ is clearly an injective order-preserving homomorphism. $\mathbb{R}$ is Archimedean: if $|x_n| \leq M \in \mathbb{N}$ for all n, then $[x] < M + 1$.

Convergence of rational approximations. Let $x \in C$. For rational $\varepsilon > 0$ choose N with $|x_n - x_m| < \varepsilon/2$ for $m, n \geq N$; then for $n \geq N$ the sequence $(\varepsilon - |x_n - x_m|)_m$ is eventually $> \varepsilon/2$, so $|[x] - x_n| < \varepsilon$ in $\mathbb{R}$. Thus the rational sequence (x_n) converges to $[x]$ in $\mathbb{R}$; by density of $\mathbb{Q}$ this holds for every real $\varepsilon > 0$.

Completeness. Let $A \subseteq \mathbb{R}$ be nonempty and bounded above. Let u_0 be the least integer that is an upper bound of A, and a_0 an integer smaller than some element of A; both exist by the Archimedean property and Theorem 4.4.2, and $a_0 < u_0$. Define rationals $a_n < u_n$ by recursion: let $m = (a_n + u_n)/2$; if m is an upper bound of A, put $(a_{n+1}, u_{n+1}) = (a_n, m)$, and otherwise $(a_{n+1}, u_{n+1}) = (m, u_n)$. Then every u_n is an upper bound, no a_n is, the sequences are monotone, and $u_n - a_n = (u_0 - a_0)/2^n \leq (u_0 - a_0)/n$ for $n \geq 1$. Hence (u_n) and (a_n) are Cauchy sequences in $\mathbb{Q}$ with the same class $s \in \mathbb{R}$, and both converge to s in $\mathbb{R}$. If $a \in A$, then $a \leq u_n$ for all n, hence $a \leq s$. If $t < s$, then $a_n > t$ for some n, and since a_n is not an upper bound, neither is t. So $s = \sup A$. □

Remark 4.8.4. Dedekind's construction [Ded72] defines a real number as a *cut*: a nonempty proper subset $\alpha \subsetneq \mathbb{Q}$ which is downward closed and has no largest element. The order is inclusion and the supremum of a bounded set of cuts is their union. It also produces a complete ordered field (Exercise 4.11.1), which by Theorem 4.7.7 is canonically isomorphic to the one constructed above. See [Rud76, Appendix to Chapter 1].

Notation 4.8.5. For $a \leq b$ in $\mathbb{R}$ we write $[a, b] = \{x : a \leq x \leq b\}$, $(a, b) = \{x : a < x < b\}$, and similarly $[a, b)$, $(a, b]$, $[a, \infty)$ and so on. We use the *extended real line* $[-\infty, \infty]$, obtained by adding a least and a greatest element, where convenient.

Proposition 4.8.6. *$|\mathbb{R}| = 2^{\aleph_0}$. In particular $\mathbb{R}$ is uncountable.*

Proof. The map $x \mapsto \{q \in \mathbb{Q} : q < x\}$ is injective by density of $\mathbb{Q}$, so $\mathbb{R} \preceq \mathcal{P}(\mathbb{Q})$. Since $\mathbb{Q}$ is countable (it injects into $\mathbb{Z}\times\mathbb{Z}$, which injects into $\mathbb{N}\times\mathbb{N}$, which is countable by Corollary 3.6.13), $\mathcal{P}(\mathbb{Q}) \preceq \mathcal{P}(\mathbb{N})$.

Conversely, for $S \subseteq \mathbb{N}$ let $f(S) = \sup\{\sum_{n\in S, n<N} 2 \cdot 3^{-(n+1)} : N \in \mathbb{N}\}$; the partial sums are at most $\sum_{n<N} 2 \cdot 3^{-(n+1)} = 1 - 3^{-N} < 1$. Let $S \neq T$ and let n be the least element of the symmetric difference, say $n \in S \setminus T$. The sums over S and T agree below n, the term $2 \cdot 3^{-(n+1)}$ occurs only for S, and the terms of T above n add up to at most $\sum_{k=n+1}^{M} 2 \cdot 3^{-(k+1)} < 3^{-(n+1)}$. Hence $f(S) - f(T) \geq 2 \cdot 3^{-(n+1)} - 3^{-(n+1)} > 0$, so f is injective. By Theorem 3.6.2, $\mathbb{R} \approx \mathcal{P}(\mathbb{N})$, and $\mathbb{R}$ is uncountable by Theorem 3.6.3. □

4.9 Irrational numbers and decimal expansions

The real numbers were constructed abstractly, as classes of Cauchy sequences. In practice a real number is written as a decimal expansion such as 3.14159 . . ., and this section connects

the two pictures. It also answers two natural questions. Which decimal expansions are rational? The answer is the eventually periodic ones (Theorem 4.9.5). And how large is $\mathbb{R}$ compared with the plane $\mathbb{R}^2$? They have the same size (Proposition 4.9.7).

Definition 4.9.1. A real number is *irrational* if it is not rational, that is, if it lies in $\mathbb{R} \setminus \mathbb{Q}$.

The first example is $\sqrt{2}$: it exists in $\mathbb{R}$ by Proposition 4.7.4, and it is not rational by Proposition 4.6.4. More generally $\sqrt[n]{m}$ is irrational unless the integer $m \geq 0$ is an n-th power (Exercise 4.11.4). The irrational numbers are what the construction of $\mathbb{R}$ adds to $\mathbb{Q}$: they fill the gaps, such as the missing supremum of Counterexample 4.6.5.

Proposition 4.9.2. *1. If $q \in \mathbb{Q}$ and $x \in \mathbb{R} \setminus \mathbb{Q}$, then $q + x$ is irrational, and so is qx if $q \neq 0$.*

2. Between any two real numbers $a < b$ there are both a rational and an irrational number.

3. $\mathbb{R} \setminus \mathbb{Q}$ is uncountable; indeed $|\mathbb{R} \setminus \mathbb{Q}| = |\mathbb{R}| = 2^{\aleph_0}$.

Proof. (1) If $q + x = r \in \mathbb{Q}$, then $x = r - q \in \mathbb{Q}$; if $qx = r$ with $q \neq 0$, then $x = r/q \in \mathbb{Q}$. (2) A rational number exists by density (Proposition 4.7.3). For an irrational one, apply density to $a/\sqrt{2} < b/\sqrt{2}$ twice to find rationals $a/\sqrt{2} < q_1 < q_2 < b/\sqrt{2}$; at least one of them, call it q, is nonzero. Then $a < q\sqrt{2} < b$, and $q\sqrt{2}$ is irrational by (1). (3) $\mathbb{Q}$ is countable (proof of Proposition 4.8.6). If $\mathbb{R} \setminus \mathbb{Q}$ were countable, then so would be $\mathbb{R} = \mathbb{Q} \cup (\mathbb{R} \setminus \mathbb{Q})$, by Corollary 3.7.6, contradicting Proposition 4.8.6. So $\mathbb{R} \setminus \mathbb{Q}$ is infinite and uncountable, and by the same corollary $|\mathbb{R}| \leq |\mathbb{Q} \sqcup (\mathbb{R} \setminus \mathbb{Q})| = \max(\aleph_0, |\mathbb{R} \setminus \mathbb{Q}|) = |\mathbb{R} \setminus \mathbb{Q}| \leq |\mathbb{R}|$. □

So in the sense of cardinality almost every real number is irrational, although both kinds are everywhere. The sum of two irrationals may be rational, as $\sqrt{2} + (-\sqrt{2}) = 0$ shows.

Decimal expansions. In an Archimedean ordered field every y has an *integer part* $\lfloor y \rfloor$, the largest integer m with $m \leq y$: the integers $m > y$ form a nonempty set that is bounded below, which has a least element m_0 by Theorem 4.4.2, and $\lfloor y \rfloor = m_0 - 1$. Then $\lfloor y \rfloor \leq y < \lfloor y \rfloor + 1$, and $\lfloor y \rfloor$ is the only integer with this property. Since every real number is an integer plus an element of $[0, 1)$, it suffices to expand the numbers in $[0, 1)$. For a sequence of digits $d_n \in \{0, 1, \ldots, 9\}$, $n \geq 1$, we write

$$0.d_1d_2d_3\ldots = \sup_{N \geq 1} s_N, \qquad s_N = \sum_{n=1}^{N} d_n 10^{-n};$$

the supremum exists because $s_N \leq \sum_{n=1}^{N} 9 \cdot 10^{-n} = 1 - 10^{-N} < 1$. (Limits of sequences of real numbers are studied in Chapter 27; here only suprema are needed, and s_N increases with N.)

Theorem 4.9.3. *Every $x \in [0, 1)$ has exactly one expansion $x = 0.d_1d_2d_3\ldots$ whose digits are not all equal to 9 from some point on. Its digits are given by*

$$d_n = \lfloor 10^n x \rfloor - 10\lfloor 10^{n-1} x \rfloor, \qquad \text{and} \qquad s_N = \frac{\lfloor 10^N x \rfloor}{10^N}.$$

Proof. Existence. Let $m_N = \lfloor 10^N x \rfloor$, so $m_0 = 0$ and $m_N \leq 10^N x < m_N + 1$. Multiplying the inequalities for $N - 1$ by 10 gives $10m_{N-1} \leq 10^N x < 10m_{N-1} + 10$, so $10m_{N-1} \leq m_N \leq 10m_{N-1}+9$, that is, $d_N = m_N - 10m_{N-1} \in \{0, \ldots, 9\}$. Summing $d_n 10^{-n} = m_n 10^{-n} - m_{n-1}10^{-(n-1)}$ over $n \leq N$ gives $s_N = m_N 10^{-N}$, so

$$s_N \leq x < s_N + 10^{-N} \qquad \text{for all } N.$$

Hence x is an upper bound of the s_N, and no $u < x$ is one: by the Archimedean property $10^{-N} < x - u$ for some N (as $10^N \geq N$), and then $s_N > x - 10^{-N} > u$. So $x = 0.d_1d_2\ldots$. If $d_n = 9$ for all $n > N$, then for $M > N$

$$s_M = s_N + 9\sum_{n=N+1}^{M} 10^{-n} = s_N + 10^{-N} - 10^{-M},$$

whose supremum over M is $s_N + 10^{-N}$, by the Archimedean property again; but this supremum is $x < s_N + 10^{-N}$. So the digits are not eventually 9.

Uniqueness. Let $x = 0.e_1e_2\ldots$ with digits e_n not eventually 9, and partial sums t_N. Fix N and choose $m > N$ with $e_m \leq 8$. For $M \geq m$,

$$t_M - t_N = \sum_{n=N+1}^{M} e_n 10^{-n} \leq \sum_{n=N+1}^{M} 9\cdot 10^{-n} - 10^{-m} < 10^{-N} - 10^{-m},$$

and the same bound holds for $N < M < m$. So $x = \sup_M t_M \leq t_N + 10^{-N} - 10^{-m} < t_N + 10^{-N}$, while $t_N \leq x$. Thus $10^N t_N$ is an integer with $10^N t_N \leq 10^N x < 10^N t_N + 1$, so $10^N t_N = \lfloor 10^N x\rfloor = m_N$ for every N, and $e_N = m_N - 10m_{N-1} = d_N$. □

Example 4.9.4.

1. $0.999\ldots = 1$: here $s_N = 1 - 10^{-N}$, and the supremum is 1. Similarly $0.4999\ldots = 0.5000\ldots$. The proof shows that this is the only ambiguity: a number has two expansions if and only if it is of the form $m/10^N$, one ending in zeros and one ending in nines (Exercise 4.11.8). This is why the theorem excludes the expansions ending in nines.

2. Long division computes the digits of a fraction. For $x = 1/7$: $10 = 1\cdot 7 + 3$, $30 = 4\cdot 7 + 2$, $20 = 2\cdot 7 + 6$, $60 = 8\cdot 7 + 4$, $40 = 5\cdot 7 + 5$, $50 = 7\cdot 7 + 1$, and the remainder 1 returns, so $1/7 = 0.142857\,142857\ldots$ repeats with period 6.

3. $\sqrt{2} - 1 = 0.41421356\ldots$: the digits are computed from $\lfloor 10^N\sqrt{2}\rfloor$, the largest integer whose square is at most $2\cdot 10^{2N}$; for instance $141^2 = 19881 \leq 20000 < 142^2 = 20164$ gives the first two digits 4, 1.

A sequence of digits is *eventually periodic* if there are $N \geq 0$ and $p \geq 1$ with $d_{n+p} = d_n$ for all $n > N$; we write $0.d_1\ldots d_N\overline{d_{N+1}\ldots d_{N+p}}$. A finite expansion, ending in zeros, is eventually periodic with period 1.

Theorem 4.9.5. *A number $x \in [0,1)$ is rational if and only if its decimal expansion is eventually periodic. More precisely:*

1. $0.\overline{c_1\ldots c_p} = \dfrac{c}{10^p - 1}$, *where $c = c_1c_2\ldots c_p$ is the integer with these decimal digits, $c = \sum_{i=1}^{p} c_i 10^{p-i}$;*

2. *if $x = a/b$ with integers $0 \leq a < b$, the digits of x are eventually periodic, with a period $p \leq b$ that begins after at most b digits.*

Proof. For a digit sequence (d_n) with partial sums s_N, multiplication by 10^k shifts the digits: since multiplying by a positive constant preserves suprema (Lemma 4.7.2),

$$10^k\cdot 0.d_1d_2\ldots = \sup_N 10^k s_{N+k} = D_k + 0.d_{k+1}d_{k+2}\ldots, \qquad D_k = \sum_{n=1}^{k} d_n 10^{k-n},$$

because $10^k s_{N+k} = D_k + \sum_{n=1}^{N} d_{k+n}10^{-n}$, and adding a constant also preserves suprema.

(1) Let $y = 0.\overline{c_1 \dots c_p}$. Shifting by p gives the same digit sequence, so $10^p y = c + y$, and $y = c/(10^p - 1)$.

Eventually periodic implies rational. If $d_{n+p} = d_n$ for $n > N$, then $10^N x = D_N + y$ with $y = 0.d_{N+1}d_{N+2}\dots$ periodic, which is rational by (1); so $x = (D_N + y)/10^N \in \mathbb{Q}$.

(2) Long division: put $r_0 = a$, and for $n \geq 1$ let $q_n = \lfloor 10r_{n-1}/b \rfloor$ and $r_n = 10r_{n-1} - bq_n$, so that $0 \leq r_n < b$. Since $r_{n-1} < b$, $q_n \leq 9$. By induction on N, $10^N a/b = Q_N + r_N/b$ with $Q_N = \sum_{n=1}^{N} q_n 10^{N-n}$: this holds for $N = 0$, and multiplying by 10 gives $10^{N+1}a/b = 10Q_N + 10r_N/b = (10Q_N + q_{N+1}) + r_{N+1}/b$. As $0 \leq r_N/b < 1$, $Q_N = \lfloor 10^N x \rfloor$, and Theorem 4.9.3 shows that the q_n are the decimal digits of x. The remainders $r_0, \dots, r_b$ are $b+1$ elements of $\{0, \dots, b-1\}$, so $r_i = r_j$ for some $i < j \leq b$ (Proposition 3.6.5). Each r_n and q_n is determined by r_{n-1}, so by induction $r_{n+p} = r_n$ for $n \geq i$, with $p = j - i$, and $q_{n+p} = q_n$ for $n > i$. □

Example 4.9.6.

1. $0.\overline{123} = 123/999 = 41/333$, $0.\overline{9} = 9/9 = 1$, and $0.1\overline{6} = (1 + 0.\overline{6})/10 = (1 + \frac{2}{3})/10 = \frac{1}{6}$.
2. The number $x = 0.1010010001000010\dots$, whose 1's are separated by blocks of $1, 2, 3, \dots$ zeros, is irrational. If its digits satisfied $d_{n+p} = d_n$ for $n > N$, take a digit $d_m = 1$ with $m > N$; then $d_{m+kp} = 1$ for all $k \geq 0$, so beyond m two consecutive 1's are never more than p places apart. But the blocks of zeros become longer than p.
3. The same argument shows that *Champernowne's number* $0.12345678910111213141 5\dots$, obtained by writing the positive integers one after another, is irrational: it contains the blocks of zeros of 10^k, of every length k, but it does not end in zeros.

The plane has as many points as the line. One might expect $\mathbb{R}^2$ to be "larger" than $\mathbb{R}$, and Cantor himself expected so; in 1877 he proved the opposite, and wrote to Dedekind that he saw it but did not believe it. There are two proofs, one through subsets of $\mathbb{N}$ and one through decimal digits.

Proposition 4.9.7. *$|\mathbb{R}^n| = |\mathbb{R}|$ for every $n \geq 1$, and the set $\mathbb{R}^{\mathbb{N}}$ of all sequences of real numbers also has the cardinality $|\mathbb{R}| = 2^{\aleph_0}$. In particular the plane $\mathbb{R}^2$, the square $[0,1]^2$ and the segment $[0,1]$ all have the same cardinality.*

Proof. By Proposition 4.8.6 there is a bijection $\mathbb{R} \to \mathcal{P}(\mathbb{N})$, so $\mathbb{R}^2 \approx \mathcal{P}(\mathbb{N}) \times \mathcal{P}(\mathbb{N})$. The map

$$\mathcal{P}(\mathbb{N}) \times \mathcal{P}(\mathbb{N}) \to \mathcal{P}(\mathbb{N}), \qquad (S, T) \mapsto \{2n : n \in S\} \cup \{2n+1 : n \in T\},$$

is a bijection: a subset U of $\mathbb{N}$ comes from exactly one pair, namely $S = \{n : 2n \in U\}$ and $T = \{n : 2n+1 \in U\}$, because every natural number is uniquely even or odd (Proposition 4.2.4). So $\mathbb{R}^2 \approx \mathcal{P}(\mathbb{N}) \approx \mathbb{R}$, and by induction $\mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R} \approx \mathbb{R} \times \mathbb{R} \approx \mathbb{R}$. For sequences, $\mathbb{R}^{\mathbb{N}} \approx \mathcal{P}(\mathbb{N})^{\mathbb{N}}$, and $(S_k)_{k\in\mathbb{N}} \mapsto \{(k, n) : n \in S_k\}$ is a bijection $\mathcal{P}(\mathbb{N})^{\mathbb{N}} \to \mathcal{P}(\mathbb{N} \times \mathbb{N})$, with inverse $U \mapsto (\{n : (k, n) \in U\})_k$. A bijection $\mathbb{N} \times \mathbb{N} \to \mathbb{N}$ (Corollary 3.6.13) induces a bijection $\mathcal{P}(\mathbb{N} \times \mathbb{N}) \to \mathcal{P}(\mathbb{N})$. Finally $[0,1] \subseteq [0,1]^2$ via $x \mapsto (x, 0)$, the square lies in $\mathbb{R}^2$, and $x \mapsto \frac{1}{2}\big(1 + \frac{x}{1+|x|}\big)$ is an injection $\mathbb{R} \to (0,1) \subseteq [0,1]$: it is strictly increasing, since $\frac{x}{1+x} = 1 - \frac{1}{1+x}$ increases for $x \geq 0$ and $\frac{x}{1+|x|}$ is odd. So $|\mathbb{R}| \leq |[0,1]| \leq |[0,1]^2| \leq |\mathbb{R}^2| = |\mathbb{R}|$, and all are equal by Theorem 3.6.2. □

Remark 4.9.8. *Cantor's interleaving of digits.* For $x = 0.a_1a_2a_3\dots$ and $y = 0.b_1b_2b_3\dots$ in $[0,1)$, written with the expansions of Theorem 4.9.3, put

$$f(x, y) = 0.a_1b_1a_2b_2a_3b_3\dots.$$

The interleaved digits are not eventually 9, since otherwise both the a_n and the b_n would be; so by the uniqueness in the theorem $f(x,y)$ determines its digits, hence x and y: $f\colon [0,1)^2 \to [0,1)$ is injective. It is not surjective: $0.191919\ldots$ would need $y = 0.999\ldots$, which is not an allowed expansion. Together with the injection $x \mapsto (x,0)$ and Theorem 3.6.2 this proves $[0,1)^2 \approx [0,1)$ again. Such a bijection is necessarily wild: none of them is continuous. Removing one point disconnects the line but not the plane, and a continuous map sends connected sets to connected sets (Chapter 18); so a continuous bijection $\mathbb{R}^2 \to \mathbb{R}$ would map the connected set $\mathbb{R}^2 \setminus \{p\}$ onto the disconnected set $\mathbb{R} \setminus \{f(p)\}$. The difference between the line and the plane, their *dimension*, is not a matter of how many points they have but of how the points are arranged, and it is detected by topology. Once $\mathbb{C}$ is constructed as $\mathbb{R}^2$ (Section 4.10), the proposition also gives $|\mathbb{C}| = |\mathbb{R}|$.

4.10 The complex numbers

Definition 4.10.1. The set of *complex numbers* is $\mathbb{C} = \mathbb{R} \times \mathbb{R}$ with

$$(a,b) + (c,d) = (a+c, b+d), \qquad (a,b)(c,d) = (ac - bd, ad + bc).$$

We identify $a \in \mathbb{R}$ with $(a,0)$ and write $i = (0,1)$, so that $(a,b) = a + bi$. For $z = a + bi$, the *real part* is $\operatorname{Re} z = a$, the *imaginary part* is $\operatorname{Im} z = b$, the *conjugate* is $\bar{z} = a - bi$, and the *absolute value* is $|z| = \sqrt{a^2 + b^2}$.

Theorem 4.10.2. *$\mathbb{C}$ is a field containing $\mathbb{R}$ as a subfield, and $i^2 = -1$. Every $z \in \mathbb{C}$ can be written uniquely as $a + bi$ with $a, b \in \mathbb{R}$. Complex conjugation is a field automorphism of $\mathbb{C}$ that is the identity exactly on $\mathbb{R}$, and for all $z, w \in \mathbb{C}$: $z\bar{z} = |z|^2$, $|zw| = |z||w|$, $|\operatorname{Re} z| \le |z|$ and $|z + w| \le |z| + |w|$.*

Proof. The ring axioms are direct computations; for instance the product is associative because both $((a,b)(c,d))(e,f)$ and $(a,b)((c,d)(e,f))$ equal $(ace - bde - adf - bcf,\ acf - bdf + ade + bce)$. The unit is $(1,0)$, and $(0,1)(0,1) = (-1,0)$. If $z = a + bi \neq 0$, then $a^2 + b^2 > 0$ and $z \cdot (a - bi)/(a^2 + b^2) = 1$. The map $a \mapsto (a,0)$ is an injective ring homomorphism. Conjugation preserves sums, and $\overline{(a+bi)(c+di)} = (ac - bd) - (ad + bc)i = (a - bi)(c - di)$; it is its own inverse and fixes $a + bi$ iff $b = 0$.

$z\bar{z} = a^2 + b^2 = |z|^2$. Then $|zw|^2 = zw\bar{z}\bar{w} = |z|^2|w|^2$, and both $|zw|$ and $|z||w|$ are non-negative, so they are equal by the uniqueness in Proposition 4.7.4. Clearly $|\operatorname{Re} z| = |a| \le \sqrt{a^2 + b^2}$. Finally $|z + w|^2 = |z|^2 + 2\operatorname{Re}(z\bar{w}) + |w|^2 \le |z|^2 + 2|z||w| + |w|^2 = (|z| + |w|)^2$. □

Proposition 4.10.3. *Every complex number has a square root: for $z = a + bi$, the number*

$$w = \sqrt{\tfrac{|z|+a}{2}} + \sigma\sqrt{\tfrac{|z|-a}{2}}\, i, \qquad \sigma = 1 \text{ if } b \ge 0,\ \sigma = -1 \text{ if } b < 0,$$

satisfies $w^2 = z$. Consequently every polynomial equation $z^2 + pz + q = 0$ with $p, q \in \mathbb{C}$ has a solution in $\mathbb{C}$.

Proof. Both radicands are non-negative since $|a| \le |z|$. We have $w^2 = \frac{|z|+a}{2} - \frac{|z|-a}{2} + 2\sigma\sqrt{\frac{|z|^2 - a^2}{4}}\, i = a + \sigma|b|i = a + bi$. For the equation, take $z = (-p + w)/2$ where $w^2 = p^2 - 4q$. □

Counterexample 4.10.4. There is no order on $\mathbb{C}$ making it an ordered field. Indeed, in an ordered field squares are non-negative and $-1 < 0$ (Lemma 4.3.4), but $-1 = i^2$.

Remark 4.10.5. The fundamental theorem of algebra, which says that every nonconstant complex polynomial has a root, is proved algebraically in Chapter 9 and again analytically in Chapter 29. The polar form $z = |z|e^{i\theta}$ requires the exponential function, which is defined in Chapter 27.

4.11 Exercises

Exercise 4.11.1. Carry out Dedekind's construction of Remark 4.8.4: define the sum of cuts α, β as $\{a + b : a \in \alpha, b \in \beta\}$, define products first for cuts containing positive rationals, and show that the cuts form a complete ordered field.

Exercise 4.11.2. Show that the only ring homomorphism $\mathbb{R} \to \mathbb{R}$ is the identity.

Solution. This is the uniqueness statement of Theorem 4.7.7 with $K = L = \mathbb{R}$. □

Exercise 4.11.3. Show that the only ring homomorphisms $\mathbb{C} \to \mathbb{C}$ that are the identity on $\mathbb{R}$ are the identity and complex conjugation. (It is a much deeper fact, relevant to Chapter 75, that $\mathbb{C}$ has many other field automorphisms, which are not the identity on $\mathbb{R}$.)

Solution. Such a homomorphism σ is determined by $\sigma(i)$, because $\sigma(a + bi) = a + b\sigma(i)$. Since $\sigma(i)^2 = \sigma(-1) = -1$, and the only solutions of $w^2 = -1$ are $\pm i$ (if $w^2 = i^2$ then $(w - i)(w + i) = 0$), we get $\sigma(i) = \pm i$. □

Exercise 4.11.4. Let $n \geq 1$ and $m \geq 0$ be integers. Show that $\sqrt[n]{m}$ is rational if and only if m is the n-th power of an integer.

Exercise 4.11.5. Let R be a commutative ring. Show that there is exactly one ring homomorphism $\mathbb{Z} \to R$.

Exercise 4.11.6. A complex number is *algebraic* if it is a root of a nonzero polynomial with integer coefficients. Show that the set of algebraic numbers is countable, and deduce that there are complex (even real) numbers that are not algebraic.

Exercise 4.11.7. Let $b \geq 2$ be an integer. Show that Theorems 4.9.3 and 4.9.5 hold in base b: every $x \in [0, 1)$ is uniquely $x = \sup_N \sum_{n=1}^{N} d_n b^{-n}$ with digits $d_n \in \{0, 1, \ldots, b - 1\}$ not eventually equal to $b - 1$, and x is rational if and only if these digits are eventually periodic. Find the binary ($b = 2$) expansion of $\frac{1}{3}$ and the ternary ($b = 3$) expansion of $\frac{1}{4}$.

Solution. Replace 10 by b and 9 by $b - 1$ in both proofs: $d_n = \lfloor b^n x \rfloor - b\lfloor b^{n-1} x \rfloor$, the partial sums are $\lfloor b^N x \rfloor / b^N$, the geometric sum is $\sum_{n=N+1}^{M} (b - 1)b^{-n} = b^{-N} - b^{-M}$, a periodic block gives $c/(b^p - 1)$, and long division uses $q_n = \lfloor b r_{n-1} / b' \rfloor$ for the denominator b'. Since $0.\overline{01}_2 = 1/(2^2 - 1) = \frac{1}{3}$ and $0.\overline{02}_3 = 2/(3^2 - 1) = \frac{1}{4}$, these are the expansions: $\frac{1}{3} = 0.010101\ldots$ in base 2 and $\frac{1}{4} = 0.020202\ldots$ in base 3. In base 3 the digits 0 and 2 alone describe the Cantor set, which is why $\frac{1}{4}$, although not an endpoint of the construction, lies in it. □

Exercise 4.11.8. Show that $x \in [0, 1)$ has a second expansion $x = 0.e_1 e_2 \ldots$, with digits ending in nines, if and only if $x = m/10^N$ for some integers $N \geq 1$ and $0 < m < 10^N$; in that case the second expansion is unique, and it is obtained from the finite one by lowering its last nonzero digit by 1 and replacing the zeros after it by nines.

Solution. Suppose $x = 0.e_1 e_2 \ldots$ with $e_n = 9$ for all $n > N$ and $e_N \leq 8$; such an $N \geq 1$ exists, since if all digits were 9 then $x = 1$. The computation in the proof of Theorem 4.9.3 gives $x = \sup_M (t_N + 10^{-N} - 10^{-M}) = t_N + 10^{-N}$. So $x = m/10^N$ with $m = 10^N t_N + 1$, an integer with $0 < m < 10^N$ whose last decimal digit is $e_N + 1 \neq 0$. Hence N is the least K such that $10^K x$ is an integer, so N is determined by x; then $t_N = x - 10^{-N}$ is determined, and so are $e_1, \ldots, e_N$, the digits of the expansion $0.e_1 \ldots e_N 000\ldots$ of t_N given by the theorem. This proves uniqueness of the second expansion, and that it exists only for $x = m/10^N$.

Conversely, let $x = m/10^N$ with $0 < m < 10^N$, and take N least, so that $10 \nmid m$. Then $\lfloor 10^M x \rfloor = 10^M x$ for $M \geq N$, so the expansion of the theorem is $0.d_1 \ldots d_N 000\ldots$, with $d_N \neq 0$ the last digit of m. The sequence $0.d_1 \ldots d_{N-1}(d_N - 1)999\ldots$ has partial sums $s_N - 10^{-N} + 10^{-N} - 10^{-M}$ for $M \geq N$, whose supremum is $s_N = x$. □

Exercise 4.11.9. Show that $\sqrt{2}+\sqrt{3}$ and $\sqrt{2}\sqrt{3}=\sqrt{6}$ are irrational, and give an example of two irrational numbers whose product is rational and of two whose sum is irrational.

Solution. $\sqrt{6}$ is irrational because 6 is not a square (Exercise 4.11.4); and $\sqrt{2}\sqrt{3}$ is a nonnegative number with square 6, so it equals $\sqrt{6}$ by uniqueness in Proposition 4.7.4. If $s=\sqrt{2}+\sqrt{3}$ were rational, then $s^2=5+2\sqrt{6}$ would be rational, and so would $\sqrt{6}=(s^2-5)/2$, a contradiction. The irrational numbers $\sqrt{2}$ and $\sqrt{2}$ have rational product 2; $\sqrt{2}$ and $\sqrt{3}$ have irrational sum, as just shown. □

Chapter 5

Model Theory

5.1 Introduction

Chapter 2 proved the compactness and Löwenheim–Skolem theorems for countable languages, as consequences of the completeness theorem, and without the axiom of choice. With the set theory of Chapter 3 (cardinals and choice) we can now say how large the models of a first-order theory can be. The downward Löwenheim–Skolem theorem (Theorem 5.2.5) produces small elementary substructures; ultraproducts and Łoś's theorem (Theorem 5.3.4) give the compactness theorem for languages of any size (Theorem 5.3.5); and together they give the upward Löwenheim–Skolem theorem (Theorem 5.4.1): a first-order theory with an infinite model has models of every infinite cardinality at least that of the language. So first-order logic cannot pin down an infinite structure up to isomorphism.

In the other direction, the Łoś–Vaught test (Theorem 5.4.3) shows that a theory with a unique model of some infinite cardinality is complete, and Cantor's back-and-forth argument (Theorem 5.4.5) supplies an example: the dense linear orders. Back-and-forth arguments are formalised by Ehrenfeucht–Fraïssé theory (Section 5.5), which leads to Lindström's theorem (Theorem 5.6.2): first-order logic is the strongest logic that has both the compactness and the Löwenheim–Skolem property. References: [CK90], [Mar02], [EFT94, Chapters XII and XIII].
Prerequisites. Chapter 2 (Mathematical Logic), Chapter 3 (Set Theory) and Chapter 4 (Number Systems).
On the way to the Hodge conjecture. No later chapter depends on this one; it can be skipped entirely.

Notation 5.1.1. We work in ZFC. Languages, formulas and structures are as in Chapter 2, but a language $\mathcal{L}$ may now have any cardinality; $|\mathcal{L}|$ is the cardinality of its set of constant, function and relation symbols, and $\|\mathcal{L}\| = \max(|\mathcal{L}|, \aleph_0)$. If the free variables of a formula φ are among the distinct variables $x_1, \dots, x_n$, we write $\varphi(x_1, \dots, x_n)$, and for elements $a_1, \dots, a_n$ of a structure $\mathcal{A}$ we write $\mathcal{A} \models \varphi[a_1, \dots, a_n]$ if $\mathcal{A} \models \varphi[s]$ for an assignment s with $s(x_i) = a_i$; by the coincidence lemma (Lemma 2.4.4) this does not depend on s. Tuples are written $\bar{a} = (a_1, \dots, a_n)$, and $\mathcal{A}$ also denotes the universe of $\mathcal{A}$. If $\mathcal{L} \subseteq \mathcal{L}'$ and $\mathcal{A}'$ is an $\mathcal{L}'$-structure, its *reduct* $\mathcal{A}'|_{\mathcal{L}}$ forgets the symbols not in $\mathcal{L}$, and $\mathcal{A}'$ is an *expansion* of $\mathcal{A}'|_{\mathcal{L}}$; by induction on formulas, an $\mathcal{L}$-formula has the same truth value in $\mathcal{A}'$ and in $\mathcal{A}'|_{\mathcal{L}}$.

Lemma 5.1.2. *A language $\mathcal{L}$ has at most $\|\mathcal{L}\|$ terms and at most $\|\mathcal{L}\|$ formulas.*

Proof. Let $\kappa = \|\mathcal{L}\|$. Let T_0 be the set of variables and constant symbols, and T_{k+1} the union of T_k with the set of terms $f(t_1, \dots, t_n)$ with $t_i \in T_k$. By induction $|T_k| \leq \kappa$: the new terms are indexed by the pairs of a function symbol and a finite tuple of elements of T_k, and there are at most $\kappa \cdot \kappa = \kappa$ of these, by Proposition 3.7.5 and Theorem 3.6.12. The union of the T_k contains

the variables and constants and is closed under the function symbols, so it contains every term, and it has cardinality at most κ by Proposition 3.7.5. The same argument, starting from the atomic formulas and closing under $\neg$, $\to$ and $\forall x$, bounds the formulas. □

5.2 Elementary substructures

Definition 5.2.1. Let $\mathcal{A}$ and $\mathcal{B}$ be $\mathcal{L}$-structures.

1. An *embedding* $h\colon \mathcal{A} \to \mathcal{B}$ is an injective map preserving constants, functions and relations as in Definition 2.4.10 (relations in both directions), but not necessarily surjective. If $\mathcal{A} \subseteq \mathcal{B}$ as sets and the inclusion is an embedding, $\mathcal{A}$ is a *substructure* of $\mathcal{B}$.

2. An embedding h is *elementary* if $\mathcal{A} \models \varphi[\bar{a}]$ if and only if $\mathcal{B} \models \varphi[h(\bar{a})]$ for every formula $\varphi(x_1, \dots, x_n)$ and every $\bar{a} \in \mathcal{A}^n$. A substructure whose inclusion is elementary is an *elementary substructure*, written $\mathcal{A} \preceq \mathcal{B}$; then $\mathcal{B}$ is an *elementary extension* of $\mathcal{A}$.

3. $\mathcal{A}$ and $\mathcal{B}$ are *elementarily equivalent*, $\mathcal{A} \equiv \mathcal{B}$, if they satisfy the same sentences, that is, $\mathrm{Th}(\mathcal{A}) = \mathrm{Th}(\mathcal{B})$.

A subset of $\mathcal{B}$ is the universe of a substructure if and only if it is nonempty, contains the constants $c^{\mathcal{B}}$ and is closed under the functions $f^{\mathcal{B}}$; the substructure is then unique. Isomorphisms are elementary (Proposition 2.4.11), and $\mathcal{A} \preceq \mathcal{B}$ implies $\mathcal{A} \equiv \mathcal{B}$, by taking $n = 0$. By induction on terms, a substructure computes the values of terms at elements of $\mathcal{A}$ as $\mathcal{B}$ does, so quantifier-free formulas have the same truth values in $\mathcal{A}$ and $\mathcal{B}$; the difference is in the quantifiers.

Example 5.2.2.

1. In the language of orders, $(\mathbb{N}, <)$ is a substructure of $(\mathbb{Z}, <)$ but not an elementary one: for $\varphi(x) = \exists y\, (y < x)$, $(\mathbb{Z}, <) \models \varphi[0]$ and $(\mathbb{N}, <) \not\models \varphi[0]$.

2. $\mathcal{A} \subseteq \mathcal{B}$ and $\mathcal{A} \equiv \mathcal{B}$ do not imply $\mathcal{A} \preceq \mathcal{B}$. The structure $(\mathbb{N}_{>0}, <)$ is a substructure of $(\mathbb{N}, <)$ and is isomorphic to it by $n \mapsto n - 1$, so the two are elementarily equivalent; but 1 has a predecessor in $\mathbb{N}$ and none in $\mathbb{N}_{>0}$, so the same formula φ shows that the inclusion is not elementary.

3. In the language of rings, $\mathbb{Z}$ is a substructure of $\mathbb{Q}$, and not even elementarily equivalent to it: the sentence $\exists y\, (y + y = 1)$ holds in $\mathbb{Q}$ and not in $\mathbb{Z}$.

The following test only involves truth in the larger structure.

Lemma 5.2.3 (Tarski–Vaught test)**.** *Let $\mathcal{A}$ be a substructure of $\mathcal{B}$. Then $\mathcal{A} \preceq \mathcal{B}$ if and only if, for every formula φ, every variable x and every assignment s with values in $\mathcal{A}$ such that $\mathcal{B} \models \exists x\, \varphi[s]$, there is $a \in \mathcal{A}$ with $\mathcal{B} \models \varphi[s[x \mapsto a]]$.*

Proof. If $\mathcal{A} \preceq \mathcal{B}$ and $\mathcal{B} \models \exists x\, \varphi[s]$, then $\mathcal{A} \models \exists x\, \varphi[s]$, so there is $a \in \mathcal{A}$ with $\mathcal{A} \models \varphi[s[x \mapsto a]]$, and then $\mathcal{B} \models \varphi[s[x \mapsto a]]$. Conversely, assume the condition. We show by induction on φ that $\mathcal{A} \models \varphi[s]$ if and only if $\mathcal{B} \models \varphi[s]$ for every assignment s with values in $\mathcal{A}$. Atomic formulas have the same truth values, as remarked above, and the cases $\neg$ and $\to$ follow from the induction hypothesis. Let $\varphi = \forall x\, \psi$. By induction, $\mathcal{A} \models \varphi[s]$ if and only if $\mathcal{B} \models \psi[s[x \mapsto a]]$ for all $a \in \mathcal{A}$. This holds if $\mathcal{B} \models \forall x\, \psi[s]$. If $\mathcal{B} \not\models \forall x\, \psi[s]$, then $\mathcal{B} \models \exists x\, \neg\psi[s]$, and the condition gives $a \in \mathcal{A}$ with $\mathcal{B} \models \neg\psi[s[x \mapsto a]]$; so both sides fail. □

Example 5.2.4. $(\mathbb{Q}, <) \preceq (\mathbb{R}, <)$. We check the Tarski–Vaught test. Let s take values in $\mathbb{Q}$, and suppose $(\mathbb{R}, <) \models \varphi[s[x \mapsto b]]$ with $b \in \mathbb{R}$. The free variables of $\exists x\, \varphi$ take finitely many values $q_1 < \cdots < q_m$ in $\mathbb{Q}$. If b is one of them we are done. Otherwise b lies in one of the open

intervals into which the q_j cut $\mathbb{R}$, and this interval contains a rational r (Proposition 4.7.3). There is an order-preserving bijection $\sigma\colon \mathbb{R} \to \mathbb{R}$ fixing all q_j with $\sigma(b) = r$: on an interval $[q_j, q_{j+1}]$ take the map that is affine on $[q_j, b]$ and on $[b, q_{j+1}]$, sending q_j, b, q_{j+1} to q_j, r, q_{j+1}, and the identity elsewhere; on an unbounded interval use an affine map of the half line fixing its endpoint, and if $m = 0$ a translation. By Proposition 2.4.11 applied to the automorphism σ, $(\mathbb{R}, <) \models \varphi[s[x \mapsto r]]$, since $\sigma \circ s[x \mapsto b]$ agrees with $s[x \mapsto r]$ on the free variables of φ. So $(\mathbb{Q}, <) \equiv (\mathbb{R}, <)$, although the two orders are not isomorphic, one being countable and the other not (Proposition 4.8.6).

Theorem 5.2.5 (Downward Löwenheim–Skolem)**.** *Let $\mathcal{B}$ be an $\mathcal{L}$-structure, $X \subseteq \mathcal{B}$, and κ a cardinal with $\|\mathcal{L}\| \leq \kappa$ and $|X| \leq \kappa \leq |\mathcal{B}|$. Then $\mathcal{B}$ has an elementary substructure $\mathcal{A}$ with $X \subseteq \mathcal{A}$ and $|\mathcal{A}| = \kappa$.*

Proof. Since $\kappa \leq |\mathcal{B}|$ there is a subset $Y \subseteq \mathcal{B}$ with $|Y| = \kappa$, and $X_0 = X \cup Y$ has cardinality κ (Corollary 3.7.6). Consider the triples $(\varphi, x, \bar{b})$ of a formula φ, a variable x and a tuple $\bar{b}$ of elements of $\mathcal{B}$ whose length is the number of free variables $y_1, \ldots, y_n$ of $\exists x\, \varphi$, listed in the order of their indices, such that $\mathcal{B} \models \exists x\, \varphi[\bar{b}]$. By the axiom of choice there is a function w choosing for each such triple a *witness* $w(\varphi, x, \bar{b}) \in \mathcal{B}$ with $\mathcal{B} \models \varphi[s]$ for the assignment sending x to the witness and y_i to b_i. Define X_{k+1} as the union of X_k with the witnesses of all triples whose tuple $\bar{b}$ has entries in X_k. There are at most κ such triples, by Lemma 5.1.2 and since X_k has at most κ finite tuples; so $|X_{k+1}| \leq \kappa$, and $A = \bigcup_k X_k$ has cardinality κ.

The set A is closed under the functions of $\mathcal{B}$: for $a_1, \ldots, a_n \in A$, all lying in some X_k, the formula $x = f(y_1, \ldots, y_n)$ has the unique witness $f^{\mathcal{B}}(a_1, \ldots, a_n)$, which lies in X_{k+1}. Likewise the witness of $x = c$ is $c^{\mathcal{B}} \in X_1$. So A is the universe of a substructure $\mathcal{A}$. It satisfies the Tarski–Vaught test: if s takes values in A and $\mathcal{B} \models \exists x\, \varphi[s]$, the finitely many values of s on the free variables of $\exists x\, \varphi$ lie in some X_k, and the corresponding witness lies in $X_{k+1} \subseteq A$. By Lemma 5.2.3, $\mathcal{A} \preceq \mathcal{B}$. □

For countable $\mathcal{L}$ and $\kappa = \aleph_0$ this refines Theorem 2.7.2: every infinite structure has a countable elementary substructure, which even contains any given countable subset. Some choice is necessary here: the proof chooses witnesses in an arbitrary structure $\mathcal{B}$, while the proof in Chapter 2 built a model from the syntax.

5.3 Ultraproducts and compactness

Definition 5.3.1. A *filter* on a set I is a set F of subsets of I with $I \in F$, $\emptyset \notin F$, and closed under finite intersections and under taking supersets. It is an *ultrafilter* if moreover, for every $X \subseteq I$, either $X \in F$ or $I \setminus X \in F$. For $i \in I$, the *principal* ultrafilter at i is $\{X \subseteq I : i \in X\}$. A family of subsets of I has the *finite intersection property* if all its finite intersections are nonempty.

Lemma 5.3.2. *1. If U is an ultrafilter, then $X \cup Y \in U$ if and only if $X \in U$ or $Y \in U$.*

2. Every family of subsets of I with the finite intersection property is contained in an ultrafilter.

Proof. (1) If $X \in U$ then $X \cup Y \in U$. If $X, Y \notin U$, then $I \setminus X$ and $I \setminus Y$ lie in U, and so does their intersection, which is disjoint from $X \cup Y$; so $X \cup Y \notin U$, as $\emptyset \notin U$.

(2) Let $\mathcal{S}$ be the family. The sets containing some finite intersection of members of $\mathcal{S}$ form a filter containing $\mathcal{S}$. Filters containing $\mathcal{S}$, ordered by inclusion, satisfy the hypothesis of Zorn's lemma (Theorem 3.7.2), since the union of a chain of filters is a filter. Let U be a maximal one and $X \subseteq I$. If X meets every member of U, the sets containing some $X \cap Y$ with $Y \in U$ form a filter containing U and X, so $X \in U$ by maximality. Otherwise $X \cap Y = \emptyset$ for some $Y \in U$, so $Y \subseteq I \setminus X$ and $I \setminus X \in U$. So U is an ultrafilter. □

Definition 5.3.3. Let $(\mathcal{A}_i)_{i\in I}$ be $\mathcal{L}$-structures and U an ultrafilter on I. On the product $\prod_i \mathcal{A}_i$ of the universes (nonempty by the axiom of choice), let $g \sim g'$ if $\{i : g(i) = g'(i)\} \in U$; this is an equivalence relation, transitivity coming from closure under intersections. The *ultraproduct* $\prod_i \mathcal{A}_i/U$ is the structure with universe the set of classes $[g]$, with $c = [(c^{\mathcal{A}_i})_i]$, $f([g_1], \dots, [g_n]) = [(f^{\mathcal{A}_i}(g_1(i), \dots, g_n(i)))_i]$, and $([g_1], \dots, [g_n]) \in R$ if and only if $\{i : (g_1(i), \dots, g_n(i)) \in R^{\mathcal{A}_i}\} \in U$. These are well defined: if $g_j \sim g'_j$ for all j, the set where $g_j(i) = g'_j(i)$ for all j is in U, and on it the two definitions agree. If all $\mathcal{A}_i$ equal $\mathcal{A}$, the ultraproduct is the *ultrapower* $\mathcal{A}^I/U$.

Theorem 5.3.4 (Łoś)**.** *Let s_i be an assignment in $\mathcal{A}_i$ for each i, and let s be the assignment in $\prod_i \mathcal{A}_i/U$ with $s(x) = [(s_i(x))_i]$. Then for every formula φ,*

$$\prod_i \mathcal{A}_i/U \models \varphi[s] \iff \{i \in I : \mathcal{A}_i \models \varphi[s_i]\} \in U.$$

Every assignment in the ultraproduct is of this form.

Proof. Every assignment is of this form: choose a representative of each value (axiom of choice). Write $\mathcal{P} = \prod_i \mathcal{A}_i/U$ and $S_\varphi = \{i : \mathcal{A}_i \models \varphi[s_i]\}$. By induction on terms, $t^{\mathcal{P}}[s] = [(t^{\mathcal{A}_i}[s_i])_i]$. For atomic formulas the claim is then the definition of $\sim$ and of $R^{\mathcal{P}}$. Since $S_{\neg\varphi} = I \setminus S_\varphi$, the case of $\neg$ follows from the ultrafilter property. Since $S_{\varphi\to\psi} = (I \setminus S_\varphi) \cup S_\psi$, the case of $\to$ follows from Lemma 5.3.2(1).

Let $\varphi = \forall x\, \psi$. For $g \in \prod_i \mathcal{A}_i$, the assignment $s[x \mapsto [g]]$ is obtained from the assignments $s_i[x \mapsto g(i)]$, so by induction $\mathcal{P} \models \psi[s[x \mapsto [g]]]$ if and only if $T_g = \{i : \mathcal{A}_i \models \psi[s_i[x \mapsto g(i)]]\} \in U$. If $S_\varphi \in U$, then $T_g \supseteq S_\varphi$ is in U for every g, so $\mathcal{P} \models \varphi[s]$. If $S_\varphi \notin U$, choose $g(i)$ with $\mathcal{A}_i \not\models \psi[s_i[x \mapsto g(i)]]$ for $i \notin S_\varphi$, and arbitrary for $i \in S_\varphi$. Then $T_g \subseteq S_\varphi$, so $T_g \notin U$ and $\mathcal{P} \not\models \varphi[s]$. □

In particular a structure $\mathcal{A}$ embeds elementarily into each of its ultrapowers, by $a \mapsto [(a)_i]$: for constant families the set in Łoś's theorem is I or $\emptyset$.

Theorem 5.3.5 (Compactness theorem)**.** *Let $\mathcal{L}$ be any language and Γ a set of $\mathcal{L}$-formulas. If every finite subset of Γ is satisfiable, then Γ is satisfiable.*

Proof. Let I be the set of finite subsets of Γ, and for $\Delta \in I$ choose a structure $\mathcal{A}_\Delta$ and an assignment s_Δ satisfying Δ. The sets $\widehat{\Delta} = \{\Delta' \in I : \Delta \subseteq \Delta'\}$ have the finite intersection property, since $\widehat{\Delta_1} \cap \dots \cap \widehat{\Delta_r}$ contains $\Delta_1 \cup \dots \cup \Delta_r$. Let U be an ultrafilter containing them (Lemma 5.3.2), and s the assignment in $\prod_\Delta \mathcal{A}_\Delta/U$ obtained from the s_Δ. For $\gamma \in \Gamma$, the set of Δ with $\mathcal{A}_\Delta \models \gamma[s_\Delta]$ contains $\widehat{\{\gamma\}} \in U$, so by Theorem 5.3.4 the ultraproduct satisfies γ under s. □

For countable languages this is Theorem 2.7.1, which was deduced from the completeness theorem; the proof above avoids formal deductions altogether, at the price of the axiom of choice.

5.4 Upward Löwenheim–Skolem and categoricity

Theorem 5.4.1 (Upward Löwenheim–Skolem)**.** *Let T be an $\mathcal{L}$-theory with an infinite model, and $\kappa \geq \|\mathcal{L}\|$ a cardinal. Then T has a model of cardinality exactly κ.*

Proof. Add new constant symbols c_α, $\alpha < \kappa$, to get a language $\mathcal{L}'$ with $\|\mathcal{L}'\| = \kappa$ (Corollary 3.7.6), and let $\Gamma = T \cup \{c_\alpha \neq c_\beta : \alpha < \beta < \kappa\}$. A finite subset of Γ mentions finitely many new constants; interpreting them as distinct elements of an infinite model of T (and the other

new constants arbitrarily) satisfies it. By Theorem 5.3.5, Γ has a model $\mathcal{B}$, and $\alpha \mapsto c_\alpha^{\mathcal{B}}$ is injective, so $|\mathcal{B}| \geq \kappa$. By Theorem 5.2.5 applied to $\mathcal{L}'$, $\mathcal{B}$ has an elementary substructure $\mathcal{A}$ of cardinality κ, which satisfies Γ like $\mathcal{B}$; its reduct to $\mathcal{L}$ is a model of T of cardinality κ. □

So a first-order theory with an infinite model never determines it up to isomorphism: it has models of arbitrarily large cardinality. Example 2.7.5 exhibited a different phenomenon, a non-standard model of the same (countable) cardinality.

Definition 5.4.2. Let κ be an infinite cardinal. A theory T is *κ-categorical* if it has a model of cardinality κ and any two models of cardinality κ are isomorphic. It is *complete* if for every sentence σ, either σ is true in all models of T or $\neg\sigma$ is. For countable languages this agrees with Definition 2.8.2, by the completeness theorem (Corollary 2.6.2).

Theorem 5.4.3 (Łoś–Vaught test)**.** *Let T be a satisfiable theory without finite models that is κ-categorical for some $\kappa \geq \|\mathcal{L}\|$. Then T is complete.*

Proof. Suppose σ is a sentence such that neither σ nor $\neg\sigma$ holds in all models of T. Then $T \cup \{\neg\sigma\}$ and $T \cup \{\sigma\}$ have models, which are infinite, so by Theorem 5.4.1 they have models $\mathcal{A}$ and $\mathcal{B}$ of cardinality κ. These are models of T, hence isomorphic, but $\mathcal{B} \models \sigma$ and $\mathcal{A} \not\models \sigma$, contradicting Proposition 2.4.11. □

Definition 5.4.4. The theory T_{DLO} of *dense linear orders without endpoints*, in the language of orders, consists of the sentences $\forall x\, \neg(x < x)$, $\forall x \forall y \forall z\, ((x < y \wedge y < z) \to x < z)$, $\forall x \forall y\, (x < y \vee x = y \vee y < x)$, $\forall x \forall y\, (x < y \to \exists z\, (x < z \wedge z < y))$, $\forall x \exists y\, (y < x)$ and $\forall x \exists y\, (x < y)$.

Its models are infinite: a model is nonempty and has no largest element. Examples are $(\mathbb{Q}, <)$, $(\mathbb{R}, <)$ and every open interval of $\mathbb{R}$.

Theorem 5.4.5 (Cantor)**.** *Any two countable dense linear orders without endpoints are isomorphic.*

Proof. Let A and B be such orders, enumerated as $a_0, a_1, \ldots$ and $b_0, b_1, \ldots$ (they are countably infinite). *Extension step*: if p is an order-preserving bijection from a finite subset of A onto a finite subset of B and $a \in A$, there is $b \in B$ such that $p \cup \{(a, b)\}$ is still order-preserving and injective. Indeed, if $a \in \operatorname{dom} p$ take $b = p(a)$; otherwise the elements of $\operatorname{dom} p$ smaller than a have images smaller than those of the elements larger than a, and we need b strictly between these two finite sets of images, which exists because B is dense and has no endpoints (and is arbitrary if $p = \emptyset$). The same holds with the roles of A and B exchanged. Starting from $p_0 = \emptyset$, let p_{2k+1} extend p_{2k} with a_k in its domain, and p_{2k+2} extend p_{2k+1} with b_k in its image (*back and forth*). The union of the p_k is an order-preserving bijection $A \to B$. □

Corollary 5.4.6. *T_{DLO} is $\aleph_0$-categorical and complete. In particular $(\mathbb{Q}, <) \equiv (\mathbb{R}, <)$, and a sentence in the language of orders holds in $(\mathbb{Q}, <)$ if and only if it holds in every dense linear order without endpoints.*

Proof. By Theorem 5.4.5, T_{DLO} is $\aleph_0$-categorical, its language is finite, and it has no finite models; apply Theorem 5.4.3 with $\kappa = \aleph_0$. □

Counterexample 5.4.7. T_{DLO} is not $2^{\aleph_0}$-categorical. The orders $(\mathbb{R}, <)$ and $(\mathbb{R} \setminus \{0\}, <)$ are dense without endpoints and have cardinality $2^{\aleph_0}$, but they are not isomorphic: in $\mathbb{R} \setminus \{0\}$ the set of negative numbers is nonempty and bounded above (by 1) but has no least upper bound, since every upper bound u is positive and $u/2$ is a smaller one, while in $\mathbb{R}$ every nonempty subset bounded above has a least upper bound (Theorem 4.8.3); an order isomorphism would preserve this property. By contrast, the theory of algebraically closed fields of a fixed characteristic is κ-categorical for every uncountable κ (such a field is determined by its transcendence degree, which equals its cardinality), hence complete by the Łoś–Vaught test; see [Mar02, Section 2.2] and Chapter 9.

5.5 Ehrenfeucht–Fraïssé theory

The proof of Cantor's theorem used only one feature of the orders: finite partial isomorphisms can always be extended, forth and back. We now make this precise and relate it to the quantifier depth of formulas. In this section and the next, languages are *relational*: they have no constant or function symbols. This is no real restriction, since an n-ary function can be replaced by its graph, an $(n+1)$-ary relation, and a constant by a unary relation holding at one point. In a relational language the terms are the variables.

Definition 5.5.1. The *quantifier rank* of a formula is defined by $\mathrm{qr}(\varphi) = 0$ for atomic φ, $\mathrm{qr}(\neg\varphi) = \mathrm{qr}(\varphi)$, $\mathrm{qr}(\varphi \to \psi) = \max(\mathrm{qr}(\varphi), \mathrm{qr}(\psi))$ and $\mathrm{qr}(\forall x\, \varphi) = \mathrm{qr}(\varphi) + 1$; so $\mathrm{qr}(\exists x\, \varphi) = \mathrm{qr}(\varphi) + 1$, and $\wedge$, $\vee$ take the maximum. For structures $\mathcal{A}$, $\mathcal{B}$, tuples $\bar{a} \in \mathcal{A}^m$, $\bar{b} \in \mathcal{B}^m$ and $n \geq 0$, write $(\mathcal{A}, \bar{a}) \equiv_n (\mathcal{B}, \bar{b})$ if $\mathcal{A} \models \varphi[\bar{a}] \iff \mathcal{B} \models \varphi[\bar{b}]$ for every formula $\varphi(x_1, \ldots, x_m)$ of quantifier rank at most n; for $m = 0$ write $\mathcal{A} \equiv_n \mathcal{B}$.

Definition 5.5.2. Let $\mathcal{A}$ and $\mathcal{B}$ be structures for a relational language. A *partial isomorphism* from $\mathcal{A}$ to $\mathcal{B}$ is an injective map p from a subset of $\mathcal{A}$ to $\mathcal{B}$ with $(a_1, \ldots, a_r) \in R^{\mathcal{A}} \iff (p(a_1), \ldots, p(a_r)) \in R^{\mathcal{B}}$ for every r-ary relation symbol R and all $a_j \in \mathrm{dom}\, p$. A set I of partial isomorphisms has the *forth property* with respect to a set J if for every $p \in I$ and $a \in \mathcal{A}$ there is $q \in J$ with $p \subseteq q$ and $a \in \mathrm{dom}\, q$, and the *back property* if for every $p \in I$ and $b \in \mathcal{B}$ there is $q \in J$ with $p \subseteq q$ and b in the image of q.

1. An *n-back-and-forth system* is a sequence $(I_k)_{0 \leq k \leq n}$ of nonempty sets of partial isomorphisms such that I_{k+1} has the forth and back properties with respect to I_k for $k < n$. We write $\mathcal{A} \cong_n \mathcal{B}$ if one exists, and $(\mathcal{A}, \bar{a}) \cong_n (\mathcal{B}, \bar{b})$ if one exists with $\bar{a} \mapsto \bar{b}$ (the map $a_j \mapsto b_j$) in I_n.

2. $\mathcal{A}$ and $\mathcal{B}$ are *partially isomorphic*, $\mathcal{A} \cong_p \mathcal{B}$, if there is a nonempty set I of partial isomorphisms with the forth and back properties with respect to itself.

For example, the finite order-preserving injections between two dense linear orders without endpoints show that any two such orders are partially isomorphic: this is the extension step in the proof of Theorem 5.4.5.

Lemma 5.5.3. *Countable partially isomorphic structures are isomorphic.*

Proof. Let I be as in the definition, and enumerate $\mathcal{A} = \{a_0, a_1, \ldots\}$ and $\mathcal{B} = \{b_0, b_1, \ldots\}$, with repetitions if the structures are finite. Choose $p_0 \in I$, then $p_{2k+1} \in I$ extending p_{2k} with a_k in its domain, and $p_{2k+2} \in I$ extending p_{2k+1} with b_k in its image. The union of the chain (p_k) is a bijection $\mathcal{A} \to \mathcal{B}$ which preserves the relations, since any finitely many elements lie in the domain of some p_k. □

Theorem 5.5.4 (Fraïssé)**.** *Let $(I_k)_{k \leq n}$ be an n-back-and-forth system from $\mathcal{A}$ to $\mathcal{B}$, let $k \leq n$, $p \in I_k$, φ a formula with $\mathrm{qr}(\varphi) \leq k$, and s an assignment in $\mathcal{A}$ whose values on the free variables of φ lie in $\mathrm{dom}\, p$. Then $\mathcal{A} \models \varphi[s]$ if and only if $\mathcal{B} \models \varphi[t]$ for any assignment t with $t(x) = p(s(x))$ for the free variables x of φ. Consequently $\mathcal{A} \cong_n \mathcal{B}$ implies $\mathcal{A} \equiv_n \mathcal{B}$, the same holds with tuples, and $\mathcal{A} \cong_p \mathcal{B}$ implies $\mathcal{A} \equiv \mathcal{B}$.*

Proof. Induction on φ. An atomic formula is $y = z$ or $R(y_1, \ldots, y_r)$ with variables y_j, and the claim holds because p is injective and preserves the relations. The cases $\neg$ and $\to$ follow from the induction hypothesis. Let $\varphi = \forall y\, \psi$, so $k \geq 1$ and $\mathrm{qr}(\psi) \leq k - 1$. Suppose $\mathcal{A} \models \varphi[s]$, and let $b \in \mathcal{B}$. By the back property there is $q \in I_{k-1}$ with $p \subseteq q$ and $b = q(a)$ for some a. Then $\mathcal{A} \models \psi[s[y \mapsto a]]$, the values of $s[y \mapsto a]$ on the free variables of ψ lie in $\mathrm{dom}\, q$, and $q(s[y \mapsto a](x)) = t[y \mapsto b](x)$ for these variables; by induction $\mathcal{B} \models \psi[t[y \mapsto b]]$. As b was

arbitrary, $\mathcal{B} \models \varphi[t]$. The converse uses the forth property in the same way. For sentences the condition on s is empty, which gives the consequences, taking $I_k = I$ for all k in the last one. □

Example 5.5.5. Let $\mathcal{L}$ be the empty language, so structures are nonempty sets. If $|\mathcal{A}| = |\mathcal{B}|$, or both have at least n elements, then $\mathcal{A} \cong_n \mathcal{B}$: let I_k be the set of injections from subsets of $\mathcal{A}$ of size at most $n - k$ into $\mathcal{B}$ (all injections with finite domain, if $|\mathcal{A}| = |\mathcal{B}|$ is finite); an injection with at most $n - k - 1$ elements in its domain can be extended by any point, since the other set has more than $n - k - 1$ elements. So a sentence of quantifier rank n cannot distinguish a set with n elements from one with $n + 1$, and no sentence of the empty language is true exactly in the finite sets of even cardinality.

For a *finite* relational language the converse of Fraïssé's theorem holds, and each class $\equiv_n$ is defined by one sentence. Fix an enumeration of all formulas of $\mathcal{L}$ (a countable set) and the variables $x_1, x_2, \ldots$; the conjunction $\bigwedge \Phi$ or disjunction $\bigvee \Phi$ of a finite nonempty set Φ of formulas is taken in the order of this enumeration.

Definition 5.5.6. Let $\mathcal{L}$ be a finite relational language. For a structure $\mathcal{A}$, a tuple $\bar{a} \in \mathcal{A}^m$ and n with $m + n \geq 1$, the *Hintikka formula* $\varphi^n_{\mathcal{A},\bar{a}}(x_1, \ldots, x_m)$ is defined by recursion on n. For $m \geq 1$, $\varphi^0_{\mathcal{A},\bar{a}}$ is the conjunction of the atomic formulas in the variables $x_1, \ldots, x_m$ that hold at $\bar{a}$ and the negations of those that do not; there are finitely many, as $\mathcal{L}$ is finite. Then

$$\varphi^{n+1}_{\mathcal{A},\bar{a}} = \varphi^0_{\mathcal{A},\bar{a}} \wedge \bigwedge_{a \in \mathcal{A}} \exists x_{m+1}\, \varphi^n_{\mathcal{A},\bar{a}a} \wedge \forall x_{m+1} \bigvee_{a \in \mathcal{A}} \varphi^n_{\mathcal{A},\bar{a}a},$$

where the conjunction and the disjunction are over the *set* of formulas $\{\varphi^n_{\mathcal{A},\bar{a}a} : a \in \mathcal{A}\}$, which is finite by Lemma 5.5.7, and the first conjunct is omitted if $m = 0$.

Lemma 5.5.7. *Let $\mathcal{L}$ be a finite relational language and $m + n \geq 1$. The set H^n_m of all formulas $\varphi^n_{\mathcal{A},\bar{a}}$, for all structures $\mathcal{A}$ and $\bar{a} \in \mathcal{A}^m$, is finite. Each has quantifier rank n, and $\mathcal{A} \models \varphi^n_{\mathcal{A},\bar{a}}[\bar{a}]$.*

Proof. Induction on n, for all m at once; this also shows that Definition 5.5.6 makes sense. The set H^0_m ($m \geq 1$) is finite, since $\varphi^0_{\mathcal{A},\bar{a}}$ is determined by the subset of the finitely many atomic formulas in $x_1, \ldots, x_m$ that hold at $\bar{a}$. The formula $\varphi^{n+1}_{\mathcal{A},\bar{a}}$ is determined by $\varphi^0_{\mathcal{A},\bar{a}}$ and by a subset of the finite set H^n_{m+1}, so H^{n+1}_m is finite. The statements about quantifier rank and truth follow by the same induction. □

Theorem 5.5.8 (Ehrenfeucht–Fraïssé)**.** *Let $\mathcal{L}$ be a finite relational language, $\bar{a} \in \mathcal{A}^m$, $\bar{b} \in \mathcal{B}^m$ and $m + n \geq 1$. The following are equivalent:*

(a) $\mathcal{B} \models \varphi^n_{\mathcal{A},\bar{a}}[\bar{b}]$*;*

(b) $(\mathcal{A}, \bar{a}) \cong_n (\mathcal{B}, \bar{b})$*;*

(c) $(\mathcal{A}, \bar{a}) \equiv_n (\mathcal{B}, \bar{b})$*.*

In particular, for $n \geq 1$ the class of structures $\mathcal{B}$ with $\mathcal{B} \equiv_n \mathcal{A}$ is the class of models of the single sentence $\varphi^n_{\mathcal{A}}$, and there are finitely many such classes.

Proof. (c) implies (a) by Lemma 5.5.7, and (b) implies (c) by Theorem 5.5.4. Assume (a). For $k \leq n$ let I_k be the set of maps $\bar{c} \mapsto \bar{d}$, where $\bar{c} \in \mathcal{A}^{m+n-k}$ and $\bar{d} \in \mathcal{B}^{m+n-k}$ extend $\bar{a}$ and $\bar{b}$ and $\mathcal{B} \models \varphi^k_{\mathcal{A},\bar{c}}[\bar{d}]$. Such a map is a well defined partial isomorphism: if the tuples are nonempty, $\varphi^k_{\mathcal{A},\bar{c}}$ contains the conjunct $\varphi^0_{\mathcal{A},\bar{c}}$, which records which equalities $x_i = x_j$ and which relations hold at $\bar{c}$, and these then hold at $\bar{d}$ as well; if they are empty, it is the empty

map. By (a), $\bar{a} \mapsto \bar{b}$ lies in I_n. Let $\bar{c} \mapsto \bar{d}$ be in I_{k+1}. For $a \in \mathcal{A}$, the conjunct $\exists x\, \varphi^k_{\mathcal{A},\bar{c}a}$ of $\varphi^{k+1}_{\mathcal{A},\bar{c}}$ gives b with $\mathcal{B} \models \varphi^k_{\mathcal{A},\bar{c}a}[\bar{d}b]$, so $\bar{c}a \mapsto \bar{d}b$ is in I_k: this is the forth property. For $b \in \mathcal{B}$, the conjunct $\forall x \bigvee_a \varphi^k_{\mathcal{A},\bar{c}a}$ gives a with $\bar{c}a \mapsto \bar{d}b$ in I_k: the back property. The forth property also shows inductively that all I_k are nonempty. So (b) holds. The last statement follows, with Lemma 5.5.7 for finiteness. □

5.6 Lindström's theorem

First-order logic is one of many possible logics: one can allow infinite conjunctions, quantifiers such as "there are uncountably many", or quantification over subsets. Lindström's theorem says that none of these extensions keeps both the compactness theorem and the Löwenheim–Skolem theorem.

Definition 5.6.1. A *logic* $\mathcal{S}$ assigns to each finite relational language $\mathcal{L}$ a set $\mathcal{S}[\mathcal{L}]$, whose elements are called $\mathcal{S}$*-sentences*, and a relation $\mathcal{A} \models_{\mathcal{S}} \psi$ between $\mathcal{L}$-structures and $\mathcal{S}$-sentences, such that:

1. (Isomorphism) isomorphic structures satisfy the same $\mathcal{S}$-sentences;
2. (Expansion) if $\mathcal{L} \subseteq \mathcal{L}'$, then $\mathcal{S}[\mathcal{L}] \subseteq \mathcal{S}[\mathcal{L}']$, and an $\mathcal{L}'$-structure satisfies $\psi \in \mathcal{S}[\mathcal{L}]$ if and only if its reduct to $\mathcal{L}$ does;
3. (Boolean operations) for $\psi, \chi \in \mathcal{S}[\mathcal{L}]$ there are $\neg\psi$ and $\psi \wedge \chi$ in $\mathcal{S}[\mathcal{L}]$ with the usual meaning;
4. (Relativisation) for $\psi \in \mathcal{S}[\mathcal{L}]$ and a unary relation symbol $P \notin \mathcal{L}$ there is $\psi^P \in \mathcal{S}[\mathcal{L} \cup \{P\}]$ such that an $(\mathcal{L} \cup \{P\})$-structure $\mathcal{A}$ with $P^{\mathcal{A}} \neq \emptyset$ satisfies ψ^P if and only if $\mathcal{A}^{(P)} \models_{\mathcal{S}} \psi$, where $\mathcal{A}^{(P)}$ is the $\mathcal{L}$-structure with universe $P^{\mathcal{A}}$ and the restrictions of the relations of $\mathcal{A}$;
5. (First-order logic) for every first-order $\mathcal{L}$-sentence σ there is $\sigma' \in \mathcal{S}[\mathcal{L}]$ with the same models.

The logic $\mathcal{S}$ has the *compactness property* if every set of $\mathcal{S}[\mathcal{L}]$-sentences whose finite subsets have models has a model, and the *Löwenheim–Skolem property* if every $\mathcal{S}$-sentence with a model has a countable model.

First-order logic is a logic in this sense, with relativisation defined by replacing each subformula $\forall x\, \varphi$ by $\forall x\, (P(x) \to \varphi)$; it has both properties, by Theorems 2.7.1 and 2.7.2. Infinitary logic with countable conjunctions has the Löwenheim–Skolem property but not the compactness property, and the logic with the quantifier "there are uncountably many" is compact for countable languages but fails the Löwenheim–Skolem property [EFT94, Chapter XIII].

Theorem 5.6.2 (Lindström)**.** *Let $\mathcal{S}$ be a logic with the compactness and the Löwenheim–Skolem properties. Then for every finite relational language $\mathcal{L}$, every $\psi \in \mathcal{S}[\mathcal{L}]$ has the same models as some first-order $\mathcal{L}$-sentence.*

Proof. Step 1. Suppose that $\psi \in \mathcal{S}[\mathcal{L}]$ has no first-order equivalent. We claim that for every $n \geq 1$ there are $\mathcal{L}$-structures $\mathcal{A}_n \models \psi$ and $\mathcal{B}_n \not\models \psi$ with $\mathcal{A}_n \cong_n \mathcal{B}_n$. Otherwise, for some n, every structure $\equiv_n$ to a model of ψ is a model of ψ (Theorem 5.5.8). Let σ be the disjunction of the finitely many sentences $\varphi^n_{\mathcal{A}} \in H^n_0$ with $\mathcal{A} \models \psi$ (or $\exists x\, (x \neq x)$ if ψ has no model). A model of ψ satisfies its own Hintikka sentence, hence σ; a model of σ is $\equiv_n$ to a model of ψ,

hence a model of ψ. So ψ has the same models as σ, a contradiction. Fix n-back-and-forth systems $(I^n_k)_{k\le n}$ from $\mathcal{A}_n$ to $\mathcal{B}_n$.

Step 2: coding. Let $\mathcal{L}^+ = \mathcal{L} \cup \{P, Q, U, W, C, <, I, G\}$ with P, Q, U, W, C unary, $<$ and I binary and G ternary. Let $\mathcal{M}_n$ be the $\mathcal{L}^+$-structure whose universe is the disjoint union of $\mathcal{A}_n$, $\mathcal{B}_n$, $\{0, 1, \dots, n\}$ and $\bigcup_k I^n_k$, with P, Q, U, W these four parts, $R^{\mathcal{M}_n} = R^{\mathcal{A}_n} \cup R^{\mathcal{B}_n}$ for $R \in \mathcal{L}$, $<$ the order of $\{0, \dots, n\}$, $C = \{n\}$, $I = \{(k, w) : w \in I^n_k\}$ and $G = \{(w, a, b) : w(a) = b\}$. Consider the following first-order $\mathcal{L}^+$-sentences:

(i) P, Q, U are nonempty, W is disjoint from P, and C holds at exactly one element, which lies in U;

(ii) $<$ is a linear order on U with a least element, and every other element of U has an immediate predecessor in U;

(iii) for every k in U there is w with $I(k, w)$, and $I(k, w)$ implies $U(k)$ and $W(w)$;

(iv) for every w in W, the relation $G(w, x, y)$ is the graph of an injective partial map from P to Q which preserves each relation of $\mathcal{L}$ in both directions (a finite conjunction, as $\mathcal{L}$ is finite);

(v) if k' is the immediate predecessor of k in U and $I(k, w)$, then for every a in P there is w' with $I(k', w')$, $\forall x \forall y\, (G(w, x, y) \to G(w', x, y))$ and $\exists y\, G(w', a, y)$; and symmetrically for every b in Q there is such a w' with $\exists x\, G(w', x, b)$.

Let $\chi \in \mathcal{S}[\mathcal{L}^+]$ be the conjunction of ψ^P, $(\neg\psi)^Q$ and the $\mathcal{S}$-versions of (i)–(v) (Definition 5.6.1(2)–(5)). Then $\mathcal{M}_n \models \chi$: the structures $\mathcal{M}^{(P)}_n = \mathcal{A}_n$ and $\mathcal{M}^{(Q)}_n = \mathcal{B}_n$ satisfy ψ and $\neg\psi$, and (v) holds because I^n_k has the forth and back properties with respect to I^n_{k-1}.

Step 3: compactness. For $j \in \mathbb{N}$ let λ_j be the first-order sentence saying that the element of C has at least j predecessors in U. A finite subset of $\{\chi\} \cup \{\lambda'_j : j \in \mathbb{N}\}$ is satisfied by $\mathcal{M}_n$ for n large, since n has n predecessors. By the compactness property there is a model $\mathcal{M}$. Call $k \in U^{\mathcal{M}}$ *infinite* if it has infinitely many predecessors; the element of $C^{\mathcal{M}}$ is infinite. An infinite k is not the least element, so it has an immediate predecessor k' by (ii), and k' is infinite, as every other predecessor of k is a predecessor of k'.

Step 4: Löwenheim–Skolem. Let J be a new unary relation symbol, and expand $\mathcal{M}$ by $J = \{w : I(k, w) \text{ for some infinite } k\}$. Let θ be the first-order sentence saying that J is nonempty and contained in W, and that for every w in J and every a in P (respectively b in Q) there is w' in J with $G(w, x, y) \to G(w', x, y)$ for all x, y and a in the domain (respectively b in the image) of w'. The expansion satisfies $\chi \wedge \theta'$: J is nonempty by (iii) applied to the element of C, and the extensions required by θ exist by (v), since the immediate predecessor of an infinite element is infinite. By the Löwenheim–Skolem property, $\chi \wedge \theta'$ has a countable model $\mathcal{N}$. Then $\mathcal{N}^{(P)}$ and $\mathcal{N}^{(Q)}$ are countable $\mathcal{L}$-structures with $\mathcal{N}^{(P)} \models \psi$ and $\mathcal{N}^{(Q)} \not\models \psi$, by relativisation, and by (iv) and θ the partial maps coded by the elements of $J^{\mathcal{N}}$ form a nonempty set of partial isomorphisms with the forth and back properties. By Lemma 5.5.3, $\mathcal{N}^{(P)} \cong \mathcal{N}^{(Q)}$, which contradicts the isomorphism property of $\mathcal{S}$. So ψ has a first-order equivalent. □

Remark 5.6.3. The theorem is from [Lin69]; we followed [EFT94, Chapter XIII]. It explains why first-order logic is the logic of this project: its two basic metatheorems, compactness and Löwenheim–Skolem, characterise it. The price is expressiveness: by Example 5.5.5 and Counterexample 2.7.4, finiteness and even cardinality are not first-order properties, and by Theorem 5.4.1 no infinite structure is characterised up to isomorphism.

5.7 Exercises

Exercise 5.7.1. Show that on an infinite set I there is an ultrafilter containing all complements of finite sets, and that such an ultrafilter is not principal. For such an ultrafilter U on $\mathbb{N}$, show that the ultrapower of the ordered field $(\mathbb{R}, 0, 1, +, \cdot, <)$ contains a positive element smaller than $1/n$ for every $n \in \mathbb{N}_{>0}$, and that it satisfies the same first-order sentences as $\mathbb{R}$.

Solution. The complements of finite sets have the finite intersection property, since a finite union of finite sets is finite and I is infinite; so they lie in an ultrafilter U (Lemma 5.3.2). It is not principal, as $I \setminus \{i\} \in U$ for each i. The element $\epsilon = [(1/(k+1))_k]$ is positive, and for $n \geq 1$ the set $\{k : 1/(k+1) < 1/n\}$ is cofinite, hence in U; by Theorem 5.3.4, $0 < \epsilon < 1/n$, where $1/n$ denotes the class of the constant family. The ultrapower is an elementary extension of $\mathbb{R}$ by the remark after Theorem 5.3.4. □

Exercise 5.7.2. Show that the theory of dense linear orders with a least and a greatest element (and at least two elements) is $\aleph_0$-categorical and complete.

Solution. Such an order is infinite, by density. Given two countable ones, the orders obtained by removing the endpoints are countable dense linear orders without endpoints, hence isomorphic (Theorem 5.4.5), and the isomorphism extends by sending endpoints to endpoints. The language is finite and there are no finite models, so Theorem 5.4.3 applies. □

Exercise 5.7.3. Show that connectedness of graphs is not first-order: there is no set of sentences in the language with one binary relation E whose models are exactly the connected graphs (symmetric irreflexive E in which any two vertices are joined by a finite path).

Solution. Suppose T were such a set. Add constants c, d and, for each n, the sentence δ_n saying that there is no path of length at most n from c to d. Every finite subset of $T \cup \{\delta_n : n\}$ is satisfied by a long path graph with c and d its endpoints, which is connected. By Theorem 5.3.5 there is a model, a connected graph in which c and d are joined by no path, a contradiction. □

Chapter 6

Categories

6.1 Introduction

Category theory is the language in which most of this project is written. This chapter introduces categories, functors and natural transformations, proves the Yoneda lemma, and develops equivalences, limits and colimits, adjoint functors, filtered colimits and additive categories. Abelian categories are treated in Chapter 15.

Categories, functors and natural transformations were introduced in [EML45], and adjoint functors in [Kan58]. Standard references are [ML98] and [Rie16]; [KS06] and the chapter on categories of [The] treat set-theoretic questions with universes, as we do.

Prerequisites. Chapter 3 (Set Theory), in particular the axiom of choice and Grothendieck universes.

On the way to the Hodge conjecture. The whole chapter is used, as a language: functors, natural transformations, the Yoneda lemma, limits and colimits, adjoint functors, filtered colimits and additive categories reappear throughout. The proofs are short and can be read quickly.

Throughout, $\mathcal{U}$ is the universe fixed in Notation 1.7.1, and a set is *small* if it is an element of $\mathcal{U}$.

6.2 Categories

Definition 6.2.1. A *category* C consists of

1. a set $\mathrm{Ob}(C)$, whose elements are called the *objects* of C;
2. for all objects X, Y, a set $\mathrm{Hom}_C(X, Y)$, whose elements are called *morphisms* from X to Y;
3. for every object X, an element $\mathrm{id}_X \in \mathrm{Hom}_C(X, X)$, the *identity* of X;
4. for all objects X, Y, Z, a map

$$\mathrm{Hom}_C(Y, Z) \times \mathrm{Hom}_C(X, Y) \longrightarrow \mathrm{Hom}_C(X, Z), \qquad (g, f) \longmapsto g \circ f,$$

called *composition*,

such that the following hold:

1. (associativity) $h \circ (g \circ f) = (h \circ g) \circ f$ for all $f \in \mathrm{Hom}_C(X, Y)$, $g \in \mathrm{Hom}_C(Y, Z)$ and $h \in \mathrm{Hom}_C(Z, W)$;

2. (identities) $f \circ \mathrm{id}_X = f = \mathrm{id}_Y \circ f$ for all $f \in \mathrm{Hom}_C(X, Y)$;

3. the sets $\mathrm{Hom}_C(X, Y)$ are pairwise disjoint.

Notation 6.2.2. We write $X \in C$ instead of $X \in \mathrm{Ob}(C)$, and $f : X \to Y$ instead of $f \in \mathrm{Hom}_C(X, Y)$. By the last axiom of Definition 6.2.1, a morphism f determines its *source* X and its *target* Y. We often write gf for $g \circ f$, and $\mathrm{Hom}(X, Y)$ when the category is clear.

Definition 6.2.3. A category C is *locally small* if $\mathrm{Hom}_C(X, Y)$ is a small set for all $X, Y \in C$. It is *small* if it is locally small and $\mathrm{Ob}(C)$ is a small set.

Remark 6.2.4. There is no set of all sets, so "the category of all sets" cannot be a category in the sense of Definition 6.2.1. The universe $\mathcal{U}$ solves this problem: it is a set, it is closed under all the usual constructions of set theory (pairs, products, power sets, sets of maps, unions indexed by small sets), and it contains every set that appears in ordinary mathematics. So we can form the category of all *small* sets without leaving ZFC.

Example 6.2.5. The category Set has as objects the small sets, that is, $\mathrm{Ob}(\mathsf{Set}) = \mathcal{U}$. For small sets X and Y, the set $\mathrm{Hom}_{\mathsf{Set}}(X, Y)$ is the set of maps from X to Y, composition is composition of maps, and id_X is the identity map. Since $\mathcal{U}$ is closed under forming sets of maps, Set is locally small. It is not small, because $\mathcal{U} \notin \mathcal{U}$.

(Strictly speaking, a map $f : X \to Y$ should be recorded together with its target Y, so that the last axiom of Definition 6.2.1 holds. We do this silently here and in similar examples.)

Example 6.2.6. In the same way there are locally small categories of small groups Grp, of small abelian groups Ab, of small rings Ring, of small vector spaces over a field k, written Vect_k, and of small topological spaces Top. In each case the morphisms are the maps that preserve the relevant structure (group homomorphisms, ring homomorphisms, linear maps, continuous maps), and composition is composition of maps. These notions are defined in later chapters.

Definition 6.2.7. A *monoid* is a set M with a map $M \times M \to M$, written $(a, b) \mapsto a \cdot b$ or simply ab, which is associative, together with an element $e \in M$ such that $ea = a = ae$ for all $a \in M$. (For a monoid given by addition, such as $(\mathbb{N}, +)$, we write $a + b$ and 0 instead.) A *homomorphism of monoids* $\varphi : M \to N$ is a map with $\varphi(ab) = \varphi(a)\varphi(b)$ for all $a, b \in M$ and $\varphi(e) = e$. The small monoids and their homomorphisms form a locally small category Mon.

Example 6.2.8. Let M be a monoid. There is a category BM with a single object $*$, with $\mathrm{Hom}_{BM}(*, *) = M$, with composition given by the multiplication of M and with $\mathrm{id}_* = e$. The axioms of a category are exactly the axioms of a monoid. Conversely, if C is a category and $X \in C$, then $\mathrm{End}(X) = \mathrm{Hom}_C(X, X)$ is a monoid under composition.

Example 6.2.9. Let P be a set with a relation $\leq$ that is reflexive and transitive (a *preorder*). There is a category, also written P, whose objects are the elements of P, with $\mathrm{Hom}_P(x, y) = \{(x, y)\}$ if $x \leq y$ and $\mathrm{Hom}_P(x, y) = \emptyset$ otherwise. Composition is forced, because every set of morphisms has at most one element; it exists by transitivity, and the identities exist by reflexivity.

Example 6.2.10. Let S be a set. The *discrete category* on S has objects the elements of S, with $\mathrm{Hom}(s, s) = \{\mathrm{id}_s\}$ and $\mathrm{Hom}(s, t) = \emptyset$ for $s \neq t$. It is the category associated with the preorder "$s \leq t$ if and only if $s = t$".

Definition 6.2.11. Let C be a category. The *opposite category* C^{op} has the same objects as C and $\mathrm{Hom}_{C^{\mathrm{op}}}(X, Y) = \mathrm{Hom}_C(Y, X)$, with the same identities and with composition $g \circ_{\mathrm{op}} f = f \circ g$.

Remark 6.2.12. The axioms of a category are symmetric under reversing all morphisms, and $(C^{\mathrm{op}})^{\mathrm{op}} = C$. So every statement proved for all categories implies a *dual* statement, obtained by applying it to opposite categories.

Definition 6.2.13. A *subcategory* $\mathcal{D}$ of a category C consists of a subset $\mathrm{Ob}(\mathcal{D}) \subseteq \mathrm{Ob}(C)$ and subsets $\mathrm{Hom}_{\mathcal{D}}(X,Y) \subseteq \mathrm{Hom}_C(X,Y)$ for $X, Y \in \mathcal{D}$, which contain the identities and are closed under composition. It is a *full* subcategory if $\mathrm{Hom}_{\mathcal{D}}(X,Y) = \mathrm{Hom}_C(X,Y)$ for all $X, Y \in \mathcal{D}$.

Example 6.2.14. The category Ab is a full subcategory of Grp. The category whose objects are small sets and whose morphisms are the bijections is a subcategory of Set that is not full.

6.3 Isomorphisms, monomorphisms and epimorphisms

Definition 6.3.1. A morphism $f : X \to Y$ in a category C is an *isomorphism* if there is a morphism $g : Y \to X$ with $g \circ f = \mathrm{id}_X$ and $f \circ g = \mathrm{id}_Y$. Two objects X and Y are *isomorphic*, written $X \cong Y$, if there is an isomorphism $X \to Y$.

Lemma 6.3.2. *Let $f : X \to Y$ be an isomorphism. There is exactly one morphism $g : Y \to X$ with $g \circ f = \mathrm{id}_X$ and $f \circ g = \mathrm{id}_Y$.*

Proof. Suppose g and g' both have the property. Then $g = g \circ \mathrm{id}_Y = g \circ (f \circ g') = (g \circ f) \circ g' = \mathrm{id}_X \circ g' = g'$. □

Notation 6.3.3. The morphism of Lemma 6.3.2 is the *inverse* of f, written f^{-1}.

Definition 6.3.4. A morphism $f : X \to Y$ is a *monomorphism* if for every object W and all $g_1, g_2 : W \to X$, the equality $f \circ g_1 = f \circ g_2$ implies $g_1 = g_2$. It is an *epimorphism* if for every object Z and all $h_1, h_2 : Y \to Z$, the equality $h_1 \circ f = h_2 \circ f$ implies $h_1 = h_2$.

Lemma 6.3.5. *Let C be a category.*

1. *Every isomorphism is both a monomorphism and an epimorphism.*
2. *A composition of monomorphisms is a monomorphism, and a composition of epimorphisms is an epimorphism.*
3. *If $g \circ f$ is a monomorphism, then f is a monomorphism. If $g \circ f$ is an epimorphism, then g is an epimorphism.*

Proof. By Remark 6.2.12, a monomorphism in C is the same thing as an epimorphism in C^{op}, so in each part it suffices to prove the statement about monomorphisms.

(1) Let f be an isomorphism and suppose $f \circ g_1 = f \circ g_2$. Composing with f^{-1} on the left gives $g_1 = g_2$.

(2) Let $f : X \to Y$ and $f' : Y \to Z$ be monomorphisms and suppose $f' \circ f \circ g_1 = f' \circ f \circ g_2$. Since f' is a monomorphism, $f \circ g_1 = f \circ g_2$, and since f is a monomorphism, $g_1 = g_2$.

(3) Suppose $f \circ g_1 = f \circ g_2$. Then $(g \circ f) \circ g_1 = (g \circ f) \circ g_2$, so $g_1 = g_2$. □

Lemma 6.3.6. *In the category* Set*, a map is a monomorphism if and only if it is injective, and an epimorphism if and only if it is surjective.*

Proof. Let $f : X \to Y$ be a map of small sets.

Suppose f is injective and $f \circ g_1 = f \circ g_2$ for maps $g_1, g_2 : W \to X$. For every $w \in W$ we have $f(g_1(w)) = f(g_2(w))$, hence $g_1(w) = g_2(w)$; so $g_1 = g_2$. Conversely, suppose f is a

monomorphism and $f(x_1) = f(x_2)$. Let $W = \{0\}$, which is a small set, and let $g_i \colon W \to X$ be the map with $g_i(0) = x_i$. Then $f \circ g_1 = f \circ g_2$, so $g_1 = g_2$, that is, $x_1 = x_2$.

Suppose f is surjective and $h_1 \circ f = h_2 \circ f$ for maps $h_1, h_2 \colon Y \to Z$. Every $y \in Y$ is of the form $f(x)$, so $h_1(y) = h_1(f(x)) = h_2(f(x)) = h_2(y)$; hence $h_1 = h_2$. Conversely, suppose f is an epimorphism. Let $Z = \{0, 1\}$, let $h_1 \colon Y \to Z$ be the map with $h_1(y) = 1$ if $y \in f(X)$ and $h_1(y) = 0$ otherwise, and let h_2 be the constant map with value 1. Then $h_1 \circ f = h_2 \circ f$, so $h_1 = h_2$, which says exactly that $f(X) = Y$. □

Counterexample 6.3.7. A morphism that is both a monomorphism and an epimorphism need not be an isomorphism. Let $P = \{0, 1\}$ with the usual order $0 \leq 1$, viewed as a category as in Example 6.2.9, and let $u \colon 0 \to 1$ be the unique morphism. Every set of morphisms of P has at most one element, so any two parallel morphisms are equal; hence every morphism of P is a monomorphism and an epimorphism. But u is not an isomorphism, because $\mathrm{Hom}_P(1, 0) = \emptyset$.

Counterexample 6.3.8. The same phenomenon occurs in categories of algebraic objects. Let $i \colon \mathbb{N} \to \mathbb{Z}$ be the inclusion, a homomorphism of monoids under addition. Then i is a monomorphism and an epimorphism in Mon, but not an isomorphism.

Indeed, if $u, v \colon M \to \mathbb{N}$ are homomorphisms with $i \circ u = i \circ v$, then $u = v$ because i is injective. Next, let $f, g \colon \mathbb{Z} \to M$ be homomorphisms with $f \circ i = g \circ i$, that is, $f(n) = g(n)$ for all $n \in \mathbb{N}$. Writing the operation of M multiplicatively, for every $n \in \mathbb{N}$ we have

$$f(-n) = f(-n)\, g(n+(-n)) = f(-n)\, g(n)\, g(-n) = f(-n)\, f(n)\, g(-n) = f(-n+n)\, g(-n) = g(-n),$$

where we used $g(0) = e$ and $f(0) = e$. Hence $f = g$. Finally, an isomorphism of monoids is in particular a bijection, and i is not surjective.

Remark 6.3.9. Counterexample 6.3.8 shows that being an epimorphism is not the same as being surjective, even in categories whose morphisms are maps. Whether a morphism is an epimorphism depends on the whole category, not only on the morphism itself.

6.4 Functors

Definition 6.4.1. Let $\mathcal{C}$ and $\mathcal{D}$ be categories. A *functor* $F \colon \mathcal{C} \to \mathcal{D}$ consists of a map $F \colon \mathrm{Ob}(\mathcal{C}) \to \mathrm{Ob}(\mathcal{D})$ and, for all $X, Y \in \mathcal{C}$, a map $F \colon \mathrm{Hom}_{\mathcal{C}}(X, Y) \to \mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))$, such that $F(\mathrm{id}_X) = \mathrm{id}_{F(X)}$ for all X and $F(g \circ f) = F(g) \circ F(f)$ for all composable morphisms f and g. A *contravariant functor* from $\mathcal{C}$ to $\mathcal{D}$ is a functor $\mathcal{C}^{\mathrm{op}} \to \mathcal{D}$.

Remark 6.4.2. Unwinding the definitions, a contravariant functor F from $\mathcal{C}$ to $\mathcal{D}$ assigns to each $f \colon X \to Y$ in $\mathcal{C}$ a morphism $F(f) \colon F(Y) \to F(X)$, and $F(g \circ f) = F(f) \circ F(g)$.

Example 6.4.3. Some functors.

1. Every category $\mathcal{C}$ has an identity functor $\mathrm{id}_{\mathcal{C}}$. If $F \colon \mathcal{C} \to \mathcal{D}$ and $G \colon \mathcal{D} \to \mathcal{E}$ are functors, then so is their composition $G \circ F$, defined on objects and on morphisms by composing maps.

2. Forgetful functors, such as $\mathsf{Grp} \to \mathsf{Set}$, which send a group to its underlying set and a homomorphism to its underlying map.

3. The covariant power set functor $\mathcal{P} \colon \mathsf{Set} \to \mathsf{Set}$ sends X to its power set $\mathcal{P}(X)$ and $f \colon X \to Y$ to the map $A \mapsto f(A)$. It is a functor because $(g \circ f)(A) = g(f(A))$.

4. The contravariant power set functor $\mathcal{P}^* \colon \mathsf{Set}^{\mathrm{op}} \to \mathsf{Set}$ sends X to $\mathcal{P}(X)$ and $f \colon X \to Y$ to the map $\mathcal{P}(Y) \to \mathcal{P}(X)$, $B \mapsto f^{-1}(B)$. It is a functor because $(g \circ f)^{-1}(C) = f^{-1}(g^{-1}(C))$.

5. If P and Q are preorders, viewed as categories, a functor $P \to Q$ is the same thing as a map $\varphi\colon P \to Q$ with $\varphi(x) \le \varphi(y)$ whenever $x \le y$.

6. If M and N are monoids, a functor $BM \to BN$ is the same thing as a homomorphism of monoids $M \to N$.

Definition 6.4.4. Let C be a locally small category and $X \in C$. The functor $h_X\colon C^{\mathrm{op}} \to \mathsf{Set}$ sends Y to $\mathrm{Hom}_C(Y, X)$ and a morphism $f\colon Y' \to Y$ of C to the map

$$h_X(f)\colon \mathrm{Hom}_C(Y, X) \to \mathrm{Hom}_C(Y', X), \qquad g \mapsto g \circ f.$$

Dually, the functor $h^X\colon C \to \mathsf{Set}$ sends Y to $\mathrm{Hom}_C(X, Y)$ and $f\colon Y \to Y'$ to $g \mapsto f \circ g$.

Lemma 6.4.5. *Let $F\colon C \to \mathcal{D}$ be a functor. If f is an isomorphism in C, then $F(f)$ is an isomorphism in $\mathcal{D}$, with inverse $F(f^{-1})$.*

Proof. If $f\colon X \to Y$, then $F(f^{-1}) \circ F(f) = F(f^{-1} \circ f) = F(\mathrm{id}_X) = \mathrm{id}_{F(X)}$, and similarly $F(f) \circ F(f^{-1}) = \mathrm{id}_{F(Y)}$. □

Definition 6.4.6. A functor $F\colon C \to \mathcal{D}$ is *faithful* (respectively *full*) if for all $X, Y \in C$ the map $\mathrm{Hom}_C(X, Y) \to \mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))$ is injective (respectively surjective). It is *fully faithful* if it is both full and faithful. It is *essentially surjective* if every object of $\mathcal{D}$ is isomorphic to an object of the form $F(X)$.

Lemma 6.4.7. *Let $F\colon C \to \mathcal{D}$ be a fully faithful functor and $f\colon X \to Y$ a morphism of C. If $F(f)$ is an isomorphism, then f is an isomorphism. In particular, if $F(X) \cong F(Y)$ then $X \cong Y$.*

Proof. Let $h\colon F(Y) \to F(X)$ be the inverse of $F(f)$. Since F is full, there is $g\colon Y \to X$ with $F(g) = h$. Then $F(g \circ f) = h \circ F(f) = \mathrm{id}_{F(X)} = F(\mathrm{id}_X)$, and since F is faithful, $g \circ f = \mathrm{id}_X$. In the same way $f \circ g = \mathrm{id}_Y$.

For the second statement, let $\varphi\colon F(X) \to F(Y)$ be an isomorphism. Since F is full, $\varphi = F(f)$ for some $f\colon X \to Y$, and f is an isomorphism by the first statement. □

Counterexample 6.4.8. Faithfulness alone does not suffice in Lemma 6.4.7. Let P be the category $0 \le 1$ of Counterexample 6.3.7, let $\mathbf{1}$ be the category with one object and one morphism, and let $F\colon P \to \mathbf{1}$ be the unique functor. Every set of morphisms of P has at most one element, so F is faithful. The morphism $u\colon 0 \to 1$ is not an isomorphism, but $F(u)$ is an identity, hence an isomorphism. (The functor F is not full: $\mathrm{Hom}_P(1, 0)$ is empty.)

Remark 6.4.9. A more natural instance of the same phenomenon is the forgetful functor $\mathsf{Top} \to \mathsf{Set}$, which is faithful. The identity map of $\mathbb{R}$, viewed as a map from $\mathbb{R}$ with the discrete topology to $\mathbb{R}$ with the Euclidean topology, is a continuous bijection, so its image in Set is an isomorphism; but it is not a homeomorphism.

6.5 Natural transformations

Definition 6.5.1. Let $F, G\colon C \to \mathcal{D}$ be functors. A *natural transformation* $\eta\colon F \Rightarrow G$ is a family of morphisms $\eta_X\colon F(X) \to G(X)$, one for each $X \in C$, such that $G(f) \circ \eta_X = \eta_Y \circ F(f)$ for every morphism $f\colon X \to Y$ of C; that is, such that the square

$$\begin{array}{ccc} F(X) & \xrightarrow{\eta_X} & G(X) \\ {\scriptstyle F(f)}\downarrow & & \downarrow{\scriptstyle G(f)} \\ F(Y) & \xrightarrow[\eta_Y]{} & G(Y) \end{array}$$

commutes. It is a *natural isomorphism* if every η_X is an isomorphism. We write $\mathrm{Nat}(F, G)$ for the set of natural transformations from F to G.

Lemma 6.5.2. *Let $\eta\colon F \Rightarrow G$ be a natural isomorphism. Then the morphisms $\eta_X^{-1}\colon G(X) \to F(X)$ form a natural transformation $\eta^{-1}\colon G \Rightarrow F$.*

Proof. Let $f\colon X \to Y$. Composing the equality $G(f) \circ \eta_X = \eta_Y \circ F(f)$ with η_Y^{-1} on the left and with η_X^{-1} on the right gives $\eta_Y^{-1} \circ G(f) = F(f) \circ \eta_X^{-1}$, which is the naturality of η^{-1}. □

Definition 6.5.3. Let $\mathcal{C}$ and $\mathcal{D}$ be categories. If $\eta\colon F \Rightarrow G$ and $\theta\colon G \Rightarrow H$ are natural transformations, their composition $\theta \circ \eta\colon F \Rightarrow H$ is given by $(\theta \circ \eta)_X = \theta_X \circ \eta_X$. The *functor category* $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ has as objects the functors $\mathcal{C} \to \mathcal{D}$, as morphisms the natural transformations, and this composition; the identity of F is the family $(\mathrm{id}_{F(X)})_X$. (Formally, a natural transformation $\eta\colon F \Rightarrow G$ is the triple $(F, G, (\eta_X)_X)$, so that the sets $\mathrm{Nat}(F, G)$ are pairwise disjoint.)

Lemma 6.5.4. *Definition 6.5.3 defines a category. A morphism η of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ is an isomorphism if and only if it is a natural isomorphism. If $\mathcal{C}$ is small and $\mathcal{D}$ is locally small, then $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ is locally small.*

Proof. If η and θ are natural, then for $f\colon X \to Y$ we have $H(f) \circ \theta_X \circ \eta_X = \theta_Y \circ G(f) \circ \eta_X = \theta_Y \circ \eta_Y \circ F(f)$, so $\theta \circ \eta$ is natural. The family of identities is clearly natural. Associativity and the identity axioms hold componentwise, because they hold in $\mathcal{D}$.

If η is an isomorphism with inverse θ, then $\theta_X \circ \eta_X = \mathrm{id}_{F(X)}$ and $\eta_X \circ \theta_X = \mathrm{id}_{G(X)}$ for every X, so each η_X is an isomorphism. Conversely, if η is a natural isomorphism, then η^{-1} of Lemma 6.5.2 is a morphism of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ that is inverse to η.

Finally, $\mathrm{Nat}(F, G)$ is a subset of the product $\prod_{X \in \mathrm{Ob}(\mathcal{C})} \mathrm{Hom}_{\mathcal{D}}(F(X), G(X))$. If $\mathcal{C}$ is small and $\mathcal{D}$ is locally small, this is a product of small sets indexed by a small set, hence small, and so is every subset of it. □

Example 6.5.5. Let k be a field. For a vector space V over k, let V^* be its dual and $\mathrm{ev}_V\colon V \to V^{**}$ the map sending v to the linear form $\varphi \mapsto \varphi(v)$. The double dual is a functor $\mathsf{Vect}_k \to \mathsf{Vect}_k$, sending $f\colon V \to W$ to $f^{**}\colon \alpha \mapsto (\psi \mapsto \alpha(\psi \circ f))$, and the maps ev_V form a natural transformation $\mathrm{ev}\colon \mathrm{id} \Rightarrow (-)^{**}$: for $v \in V$ and $\psi \in W^*$,

$$f^{**}(\mathrm{ev}_V(v))(\psi) = \mathrm{ev}_V(v)(\psi \circ f) = \psi(f(v)) = \mathrm{ev}_W(f(v))(\psi).$$

On the full subcategory of finite-dimensional vector spaces it is a natural isomorphism, since there each ev_V is an isomorphism.

Remark 6.5.6. A finite-dimensional vector space V is also isomorphic to its dual V^*, but an isomorphism $V \to V^*$ depends on a choice, such as a basis. The notion of a natural transformation was introduced to make precise the difference between "canonical" isomorphisms, such as $V \cong V^{**}$, and isomorphisms that depend on choices.

Example 6.5.7. Let $n \geq 1$. For a commutative ring R, the determinant is a group homomorphism $\det_R\colon \mathrm{GL}_n(R) \to R^\times$. Both GL_n and $(-)^\times$ are functors from commutative rings to groups, and det is a natural transformation between them: if $\varphi\colon R \to S$ is a ring homomorphism and $A \in \mathrm{GL}_n(R)$, then $\det_S(\varphi(A)) = \varphi(\det_R(A))$, because the determinant is a polynomial with integer coefficients in the entries of the matrix.

6.6 The Yoneda lemma

In this section C is a locally small category, so that the functors $h_X : C^{\mathrm{op}} \to \mathsf{Set}$ of Definition 6.4.4 are defined.

Theorem 6.6.1 (Yoneda lemma). *Let $X \in C$ and let $F : C^{\mathrm{op}} \to \mathsf{Set}$ be a functor. The map*

$$\Phi\colon \mathrm{Nat}(h_X, F) \longrightarrow F(X), \qquad \eta \longmapsto \eta_X(\mathrm{id}_X)$$

is a bijection. Its inverse sends $\xi \in F(X)$ to the natural transformation η^ξ given by $\eta^\xi_Y(g) = F(g)(\xi)$ for $Y \in C$ and $g \in \mathrm{Hom}_C(Y, X)$.

Proof. First, η^ξ is natural. Let $f : Y' \to Y$ be a morphism of C and $g \in \mathrm{Hom}_C(Y, X)$. Using that F is contravariant (Remark 6.4.2),

$$\eta^\xi_{Y'}(h_X(f)(g)) = \eta^\xi_{Y'}(g \circ f) = F(g \circ f)(\xi) = F(f)(F(g)(\xi)) = F(f)(\eta^\xi_Y(g)),$$

which is the naturality condition for f.

Second, $\Phi(\eta^\xi) = \eta^\xi_X(\mathrm{id}_X) = F(\mathrm{id}_X)(\xi) = \xi$.

Third, let $\eta : h_X \Rightarrow F$ be natural and $g : Y \to X$. The naturality of η with respect to g gives $\eta_Y(h_X(g)(\mathrm{id}_X)) = F(g)(\eta_X(\mathrm{id}_X))$. Since $h_X(g)(\mathrm{id}_X) = \mathrm{id}_X \circ g = g$, this says $\eta_Y(g) = F(g)(\Phi(\eta)) = \eta^{\Phi(\eta)}_Y(g)$. Hence $\eta = \eta^{\Phi(\eta)}$.

The second and third steps show that $\xi \mapsto \eta^\xi$ is inverse to Φ. □

Remark 6.6.2. The Yoneda lemma says that a natural transformation out of h_X is determined by what it does to the single element id_X, and that this element can be chosen freely. Informally: an object is determined by the morphisms into it.

Proposition 6.6.3. *The bijection Φ of Theorem 6.6.1 is natural in F and in X:*

1. *if $\theta : F \Rightarrow F'$ is a natural transformation, then $\Phi(\theta \circ \eta) = \theta_X(\Phi(\eta))$ for all $\eta \in \mathrm{Nat}(h_X, F)$;*
2. *if $a : X' \to X$ is a morphism and $h_a : h_{X'} \Rightarrow h_X$ is the natural transformation given by $(h_a)_Y(g) = a \circ g$, then $\Phi(\eta \circ h_a) = F(a)(\Phi(\eta))$ for all $\eta \in \mathrm{Nat}(h_X, F)$.*

Proof. We first check that h_a is natural: for $f : Y' \to Y$ and $g : Y \to X'$ we have $a \circ (g \circ f) = (a \circ g) \circ f$, that is, $(h_a)_{Y'}(h_{X'}(f)(g)) = h_X(f)((h_a)_Y(g))$.

(1) $\Phi(\theta \circ \eta) = \theta_X(\eta_X(\mathrm{id}_X)) = \theta_X(\Phi(\eta))$.

(2) $\Phi(\eta \circ h_a) = \eta_{X'}((h_a)_{X'}(\mathrm{id}_{X'})) = \eta_{X'}(a)$. By the third step of the proof of Theorem 6.6.1, $\eta_{X'}(a) = F(a)(\Phi(\eta))$. □

Corollary 6.6.4. *For all $X, X' \in C$, the map*

$$\mathrm{Hom}_C(X', X) \longrightarrow \mathrm{Nat}(h_{X'}, h_X), \qquad a \longmapsto h_a$$

is a bijection. Consequently, $X \mapsto h_X$, $a \mapsto h_a$ is a fully faithful functor $C \to \mathrm{Fun}(C^{\mathrm{op}}, \mathsf{Set})$, called the Yoneda embedding.

Proof. Apply Theorem 6.6.1 with X' in place of X and $F = h_X$. Then $\Phi(h_a) = (h_a)_{X'}(\mathrm{id}_{X'}) = a$, so the map $a \mapsto h_a$ is a right inverse of the bijection Φ, hence equal to its inverse and bijective. The identities $h_{\mathrm{id}_X} = \mathrm{id}_{h_X}$ and $h_{a \circ b} = h_a \circ h_b$ follow from the identity axiom and from associativity in C, so $X \mapsto h_X$ is a functor, and it is fully faithful by the first statement. □

Corollary 6.6.5. *Let $X, X' \in C$. If there is a natural isomorphism $h_{X'} \Rightarrow h_X$, then $X' \cong X$.*

Proof. By Lemma 6.5.4, a natural isomorphism $h_{X'} \Rightarrow h_X$ is an isomorphism in $\mathrm{Fun}(C^{\mathrm{op}}, \mathsf{Set})$. The Yoneda embedding is fully faithful by Corollary 6.6.4, so the claim follows from Lemma 6.4.7. □

Definition 6.6.6. A functor $F\colon C^{\mathrm{op}} \to \mathsf{Set}$ is *representable* if there exist $X \in C$ and a natural isomorphism $h_X \Rightarrow F$. By Theorem 6.6.1, such a natural isomorphism is η^ξ for a unique $\xi \in F(X)$; the pair (X, ξ) is said to *represent* F.

Example 6.6.7. The contravariant power set functor $\mathcal{P}^*$ of Example 6.4.3 is represented by the pair $(\{0,1\}, \{1\})$. Indeed, for a small set S the map $\eta_S^{\{1\}}$ sends $\chi\colon S \to \{0,1\}$ to $\mathcal{P}^*(\chi)(\{1\}) = \chi^{-1}(1)$, and this is a bijection $\mathrm{Hom}_{\mathsf{Set}}(S, \{0,1\}) \to \mathcal{P}(S)$: its inverse sends a subset $A \subseteq S$ to its indicator function.

6.7 Equivalences of categories

Definition 6.7.1. A functor $F\colon C \to \mathcal{D}$ is an *equivalence of categories* if there are a functor $G\colon \mathcal{D} \to C$ and natural isomorphisms $G \circ F \Rightarrow \mathrm{id}_C$ and $F \circ G \Rightarrow \mathrm{id}_{\mathcal{D}}$; such a G is a *quasi-inverse* of F. It is an *isomorphism of categories* if moreover $G \circ F = \mathrm{id}_C$ and $F \circ G = \mathrm{id}_{\mathcal{D}}$. Two categories are *equivalent* if there is an equivalence between them.

Lemma 6.7.2. *An equivalence of categories is fully faithful and essentially surjective.*

Proof. Let G, $\eta\colon GF \Rightarrow \mathrm{id}$ and $\varepsilon\colon FG \Rightarrow \mathrm{id}$ be as in Definition 6.7.1. Every $Y \in \mathcal{D}$ is isomorphic to $F(G(Y))$ via ε_Y, so F is essentially surjective. For $f\colon X \to X'$, naturality of η gives $f = \eta_{X'} \circ GF(f) \circ \eta_X^{-1}$; so $F(f)$ determines f and F is faithful. By symmetry G is faithful. Let $g\colon F(X) \to F(X')$ and put $f = \eta_{X'} \circ G(g) \circ \eta_X^{-1}$. By the same formula applied to f, $GF(f) = \eta_{X'}^{-1} \circ f \circ \eta_X = G(g)$, and since G is faithful, $F(f) = g$. So F is full. □

Theorem 6.7.3. *A functor $F\colon C \to \mathcal{D}$ is an equivalence of categories if and only if it is fully faithful and essentially surjective.*

Proof. One direction is Lemma 6.7.2. Conversely, for each $Y \in \mathcal{D}$ the set of pairs (X, e) with $X \in C$ and $e\colon F(X) \to Y$ an isomorphism is nonempty. By the axiom of choice (Definition 3.7.1) we may choose such a pair $(G(Y), \varepsilon_Y)$ for every Y. For $g\colon Y \to Y'$, let $G(g)$ be the unique morphism $G(Y) \to G(Y')$ with $F(G(g)) = \varepsilon_{Y'}^{-1} \circ g \circ \varepsilon_Y$; it exists and is unique because F is fully faithful. By uniqueness, G preserves identities and composition, and by construction $\varepsilon\colon FG \Rightarrow \mathrm{id}_{\mathcal{D}}$ is a natural isomorphism.

For $X \in C$ let $\eta_X\colon GF(X) \to X$ be the unique morphism with $F(\eta_X) = \varepsilon_{F(X)}$. It is an isomorphism by Lemma 6.4.7. For $f\colon X \to X'$ we have $F(f \circ \eta_X) = F(f) \circ \varepsilon_{F(X)}$ and $F(\eta_{X'} \circ GF(f)) = \varepsilon_{F(X')} \circ \varepsilon_{F(X')}^{-1} \circ F(f) \circ \varepsilon_{F(X)}$, which are equal; as F is faithful, η is natural. □

Example 6.7.4. Let k be a field, and let Mat_k be the category whose objects are the natural numbers, whose morphisms $n \to m$ are the $m \times n$ matrices with entries in k, and whose composition is matrix multiplication. The functor from Mat_k to the category of finite-dimensional vector spaces sending n to k^n and a matrix to the corresponding linear map is fully faithful, and essentially surjective because every finite-dimensional vector space has a basis. So it is an equivalence: linear algebra of finite-dimensional spaces is "the same" as matrix algebra.

Counterexample 6.7.5. Equivalent categories need not be isomorphic. Let FinSet be the category of finite small sets and maps, and $\mathcal{N}$ its full subcategory whose objects are the natural numbers. Every finite set is isomorphic to a natural number (Definition 3.6.4), so the

inclusion $\mathcal{N} \to \mathsf{FinSet}$ is fully faithful and essentially surjective, hence an equivalence. But an isomorphism of categories is a bijection on objects, and $\mathrm{Ob}(\mathcal{N}) = \omega$ is countable while $\mathrm{Ob}(\mathsf{FinSet})$ contains the singletons $\{x\}$ for all $x \in \mathcal{U}$, and $\mathcal{U}$ is uncountable since it contains the uncountable set $\mathbb{R}$ as a subset.

6.8 Limits

Definition 6.8.1. Let $\mathcal{I}$ be a small category and $F\colon \mathcal{I} \to \mathcal{C}$ a functor, called a *diagram* of shape $\mathcal{I}$. A *cone* over F is an object L together with morphisms $\lambda_i\colon L \to F(i)$ for all $i \in \mathcal{I}$ such that $F(u) \circ \lambda_i = \lambda_j$ for every $u\colon i \to j$. A *limit* of F is a cone (L, λ) such that for every cone (M, μ) there is a unique morphism $m\colon M \to L$ with $\lambda_i \circ m = \mu_i$ for all i. We write $L = \lim F$ or $\lim_{i\in\mathcal{I}} F(i)$.

Lemma 6.8.2. *If (L, λ) and (L', λ') are limits of F, there is a unique morphism $m\colon L' \to L$ with $\lambda_i \circ m = \lambda'_i$ for all i, and it is an isomorphism.*

Proof. Existence and uniqueness of m is the definition. Let $m'\colon L \to L'$ be the morphism given by the universal property of L'. Then $m \circ m'$ and id_L are both morphisms of cones from (L, λ) to itself, so they are equal by uniqueness; similarly $m' \circ m = \mathrm{id}_{L'}$. □

Example 6.8.3.

1. If $\mathcal{I}$ is empty, a limit is a *terminal object*: an object T such that every object has exactly one morphism to T.
2. If $\mathcal{I}$ is a discrete category, a limit of $(X_i)_{i\in\mathcal{I}}$ is a *product* $\prod_i X_i$ with projections p_i.
3. If $\mathcal{I}$ has two objects $0, 1$ and two non-identity morphisms $u, v\colon 0 \to 1$, a diagram is a pair of parallel morphisms $f, g\colon X \to Y$, and a limit is an *equaliser*: a morphism $e\colon E \to X$ with $fe = ge$ through which every h with $fh = gh$ factors uniquely.
4. If $\mathcal{I}$ is $1 \to 0 \leftarrow 2$, a diagram is a pair $f\colon X \to Z$, $g\colon Y \to Z$, and a limit is a *fibre product* $X \times_Z Y$.
5. If $\mathcal{I}$ is the poset $\mathbb{N}$ with the opposite order, a limit of a sequence $\cdots \to X_2 \to X_1 \to X_0$ is an *inverse limit*.

Definition 6.8.4. A category *has limits* (respectively *finite limits*) if every diagram $F\colon \mathcal{I} \to \mathcal{C}$ with $\mathcal{I}$ small (respectively with finitely many morphisms) has a limit. A functor $G\colon \mathcal{C} \to \mathcal{D}$ *preserves* the limit (L, λ) of F if $(G(L), G(\lambda))$ is a limit of $G \circ F$.

Proposition 6.8.5. Set *has limits. For $F\colon \mathcal{I} \to \mathsf{Set}$ with $\mathcal{I}$ small, a limit is*

$$\lim F = \left\{(x_i) \in \prod_{i\in\mathrm{Ob}(\mathcal{I})} F(i) : F(u)(x_i) = x_j \text{ for all } u\colon i \to j\right\}$$

with the projections $\lambda_i((x_k)_k) = x_i$.

Proof. The set $\lim F$ is small by Lemma 3.8.2, and it is a cone by construction. If (M, μ) is a cone, the map $m(y) = (\mu_i(y))_i$ lands in $\lim F$, satisfies $\lambda_i \circ m = \mu_i$, and is the only such map. □

Theorem 6.8.6. *If $\mathcal{C}$ has products indexed by small sets and equalisers, then it has limits. If $\mathcal{C}$ has a terminal object, binary products and equalisers, then it has finite limits.*

Proof. Let $F\colon \mathcal{I} \to \mathcal{C}$ be a diagram. Let $P = \prod_i F(i)$ over the objects of $\mathcal{I}$, and $Q = \prod_u F(t(u))$ over all morphisms $u\colon s(u) \to t(u)$ of $\mathcal{I}$, with projections p_i and q_u. Define $a, b\colon P \to Q$ by $q_u \circ a = F(u) \circ p_{s(u)}$ and $q_u \circ b = p_{t(u)}$. Let $e\colon L \to P$ be an equaliser of a and b, and $\lambda_i = p_i \circ e$. The equation $ae = be$ says exactly that $F(u) \circ \lambda_{s(u)} = \lambda_{t(u)}$ for all u, so (L, λ) is a cone. If (M, μ) is a cone, the morphism $\mu\colon M \to P$ with $p_i \circ \mu = \mu_i$ satisfies $a\mu = b\mu$, so it factors uniquely as $\mu = e \circ m$; and a morphism m satisfies $\lambda_i \circ m = \mu_i$ for all i if and only if $e \circ m = \mu$. So (L, λ) is a limit. If $\mathcal{I}$ is finite, only finite products are needed, and these can be built from binary products and a terminal object (the empty product) by induction. □

Proposition 6.8.7. *Let $\mathcal{C}$ be locally small, $F\colon \mathcal{I} \to \mathcal{C}$ a diagram and (L, λ) a cone over F. Then (L, λ) is a limit if and only if for every $X \in \mathcal{C}$ the map*

$$\mathrm{Hom}_{\mathcal{C}}(X, L) \longrightarrow \lim_{i \in \mathcal{I}} \mathrm{Hom}_{\mathcal{C}}(X, F(i)), \qquad m \longmapsto (\lambda_i \circ m)_i$$

is a bijection, where the right-hand side is the limit in Set *of Proposition 6.8.5. In particular the functors $h^X = \mathrm{Hom}_{\mathcal{C}}(X, -)$ preserve all limits.*

Proof. An element of the right-hand side is exactly a cone with vertex X, so bijectivity for all X is the definition of a limit. □

Proposition 6.8.8. *Let $\mathcal{A}$ be a category and suppose that $\mathcal{C}$ has limits of shape $\mathcal{I}$. Then* $\mathrm{Fun}(\mathcal{A}, \mathcal{C})$ *has limits of shape $\mathcal{I}$, computed pointwise: for $F\colon \mathcal{I} \to \mathrm{Fun}(\mathcal{A}, \mathcal{C})$ there is a limit L with $L(a) = \lim_i F(i)(a)$ for all $a \in \mathcal{A}$.*

Proof. For each a choose a limit $(L(a), \lambda^a)$ of $i \mapsto F(i)(a)$. For $f\colon a \to a'$, the morphisms $F(i)(f) \circ \lambda^a_i$ form a cone over $i \mapsto F(i)(a')$ (by naturality of the $F(u)$), so there is a unique $L(f)\colon L(a) \to L(a')$ with $\lambda^{a'}_i \circ L(f) = F(i)(f) \circ \lambda^a_i$. Uniqueness shows that L is a functor and that the $\lambda_i = (\lambda^a_i)_a$ are natural transformations $L \Rightarrow F(i)$ forming a cone. If (M, μ) is a cone in the functor category, then for each a there is a unique m_a with $\lambda^a_i \circ m_a = \mu_{i,a}$, and uniqueness again shows that $m = (m_a)_a$ is natural; it is the unique morphism of cones. □

Counterexample 6.8.9. The category Field of small fields and ring homomorphisms does not have binary products. First, a ring homomorphism $f\colon K \to K'$ between fields is injective: if $f(a) = 0$ with $a \neq 0$ then $1 = f(a)f(a^{-1}) = 0$. Let $\mathbb{F}_2 = \{0, 1\}$ be the field with $1 + 1 = 0$. If P were a product of $\mathbb{Q}$ and $\mathbb{F}_2$, there would be homomorphisms $P \to \mathbb{Q}$ and $P \to \mathbb{F}_2$. The second one sends $1 + 1$ to 0, so $1 + 1 = 0$ in P by injectivity; but then the first one sends 0 to $2 \neq 0$.

6.9 Colimits

Definition 6.9.1. A *cocone* under a diagram $F\colon \mathcal{I} \to \mathcal{C}$ is an object C with morphisms $\gamma_i\colon F(i) \to C$ such that $\gamma_j \circ F(u) = \gamma_i$ for all $u\colon i \to j$. A *colimit* is a cocone (C, γ) such that for every cocone (D, δ) there is a unique $m\colon C \to D$ with $m \circ \gamma_i = \delta_i$ for all i. We write $C = \mathrm{colim}\, F$.

Remark 6.9.2. A colimit of F is the same thing as a limit of the corresponding diagram $\mathcal{I}^{\mathrm{op}} \to \mathcal{C}^{\mathrm{op}}$. By duality (Remark 6.2.12), all results of Section 6.8 have colimit versions: colimits are unique up to unique isomorphism, colimits can be built from coproducts and coequalisers, and (C, γ) is a colimit if and only if $\mathrm{Hom}(C, X) \to \lim_i \mathrm{Hom}(F(i), X)$ is bijective for all X. The colimit analogues of the examples in Example 6.8.3 are *initial objects*, *coproducts* $\coprod_i X_i$, *coequalisers*, *pushouts* $X \sqcup_Z Y$ and *direct limits*.

Proposition 6.9.3. Set *has colimits. For* $F\colon \mathcal{I} \to \mathsf{Set}$ *with* $\mathcal{I}$ *small, let* $\sim$ *be the smallest equivalence relation on* $\coprod_i F(i) = \{(i,x) : i \in \mathrm{Ob}(\mathcal{I}), x \in F(i)\}$ *with* $(i,x) \sim (j, F(u)(x))$ *for all* $u\colon i \to j$ *and* $x \in F(i)$. *Then* $\operatorname{colim} F = (\coprod_i F(i))/{\sim}$, *with* $\gamma_i(x) = [(i,x)]$.

Proof. The smallest equivalence relation containing a relation R exists: it is the intersection of all equivalence relations containing R, a subset of the square of the set. The maps γ_i form a cocone by construction. A cocone (D, δ) gives a map $\coprod_i F(i) \to D$, $(i,x) \mapsto \delta_i(x)$, whose fibres define an equivalence relation containing the generating relation; so it factors uniquely through the quotient (Proposition 3.3.9). □

Example 6.9.4. In Set, the coproduct is the disjoint union, and the initial object is $\emptyset$. In the category of abelian groups the coproduct of a family is its direct sum, and in the category of groups it is the free product; these are constructed in Chapter 7.

6.10 Adjoint functors

In this section all categories are locally small.

Definition 6.10.1. An *adjunction* between functors $F\colon \mathcal{C} \to \mathcal{D}$ and $G\colon \mathcal{D} \to \mathcal{C}$ is a family of bijections

$$\varphi_{X,Y}\colon \mathrm{Hom}_{\mathcal{D}}(F(X), Y) \longrightarrow \mathrm{Hom}_{\mathcal{C}}(X, G(Y))$$

for $X \in \mathcal{C}$, $Y \in \mathcal{D}$, natural in X and Y: for $f\colon X' \to X$, $g\colon F(X) \to Y$ and $h\colon Y \to Y'$, $\varphi(g \circ F(f)) = \varphi(g) \circ f$ and $\varphi(h \circ g) = G(h) \circ \varphi(g)$. We say F is *left adjoint* to G, and G *right adjoint* to F, written $F \dashv G$. The *unit* and *counit* are $\eta_X = \varphi(\mathrm{id}_{F(X)})\colon X \to GF(X)$ and $\varepsilon_Y = \varphi^{-1}(\mathrm{id}_{G(Y)})\colon FG(Y) \to Y$.

Proposition 6.10.2. *Let* $F \dashv G$. *Then* $\eta\colon \mathrm{id}_{\mathcal{C}} \Rightarrow GF$ *and* $\varepsilon\colon FG \Rightarrow \mathrm{id}_{\mathcal{D}}$ *are natural,* $\varphi(g) = G(g) \circ \eta_X$, $\varphi^{-1}(f) = \varepsilon_Y \circ F(f)$, *and the* triangle identities

$$\varepsilon_{F(X)} \circ F(\eta_X) = \mathrm{id}_{F(X)}, \qquad G(\varepsilon_Y) \circ \eta_{G(Y)} = \mathrm{id}_{G(Y)}$$

hold. Conversely, if $\eta\colon \mathrm{id} \Rightarrow GF$ *and* $\varepsilon\colon FG \Rightarrow \mathrm{id}$ *are natural transformations satisfying the triangle identities, then* $\varphi(g) = G(g) \circ \eta_X$ *defines an adjunction with unit* η *and counit* ε.

Proof. By naturality in Y, $\varphi(g) = \varphi(g \circ \mathrm{id}_{F(X)}) = G(g) \circ \varphi(\mathrm{id}_{F(X)}) = G(g) \circ \eta_X$. By naturality in X, for $f\colon X \to G(Y)$, $\varphi^{-1}(f) = \varphi^{-1}(\mathrm{id}_{G(Y)} \circ f) = \varphi^{-1}(\mathrm{id}_{G(Y)}) \circ F(f) = \varepsilon_Y \circ F(f)$. Naturality of η: for $f\colon X' \to X$, $GF(f) \circ \eta_{X'} = \varphi(F(f)) = \varphi(\mathrm{id}_{F(X)} \circ F(f)) = \eta_X \circ f$; naturality of ε is dual. The triangle identities are $\varphi^{-1}(\eta_X) = \mathrm{id}_{F(X)}$ and $\varphi(\varepsilon_Y) = \mathrm{id}_{G(Y)}$.

Conversely, define $\varphi(g) = G(g) \circ \eta_X$ and $\psi(f) = \varepsilon_Y \circ F(f)$. Then $\psi(\varphi(g)) = \varepsilon_Y \circ FG(g) \circ F(\eta_X) = g \circ \varepsilon_{F(X)} \circ F(\eta_X) = g$ by naturality of ε and the first triangle identity, and similarly $\varphi(\psi(f)) = f$. Naturality of φ in X follows from naturality of η, and in Y from functoriality of G. □

Proposition 6.10.3. *If* G *and* G' *are both right adjoint to* F, *there is a unique natural isomorphism* $\theta\colon G \Rightarrow G'$ *compatible with the adjunction bijections, that is, with* $\varphi'_{X,Y} = \mathrm{Hom}(X, \theta_Y) \circ \varphi_{X,Y}$.

Proof. For fixed Y, the bijections $\varphi'_{X,Y} \circ \varphi^{-1}_{X,Y}\colon \mathrm{Hom}(X, G(Y)) \to \mathrm{Hom}(X, G'(Y))$ are natural in X, so they form a natural isomorphism $h_{G(Y)} \Rightarrow h_{G'(Y)}$. By Corollary 6.6.4 it is h_{θ_Y} for a unique $\theta_Y\colon G(Y) \to G'(Y)$, which is an isomorphism because the Yoneda embedding is fully faithful (Lemma 6.4.7). Naturality in Y follows from naturality of φ and φ' in Y and faithfulness of the Yoneda embedding. □

Theorem 6.10.4. *A right adjoint preserves all limits that exist, and a left adjoint preserves all colimits that exist.*

Proof. Let $F \dashv G$ and let (L, λ) be a limit of $D\colon \mathcal{I} \to \mathcal{D}$. For every $X \in \mathcal{C}$ we have bijections, natural in X,

$$\mathrm{Hom}(X, G(L)) \cong \mathrm{Hom}(F(X), L) \cong \lim_i \mathrm{Hom}(F(X), D(i)) \cong \lim_i \mathrm{Hom}(X, G(D(i))),$$

by Proposition 6.8.7 in the middle. By naturality of φ in Y, the composite sends m to $(G(\lambda_i) \circ m)_i$. So $(G(L), G(\lambda))$ is a limit by Proposition 6.8.7. The statement about left adjoints follows by duality. □

Example 6.10.5.

1. *Free monoids.* For a small set S, let $W(S)$ be the set of finite sequences of elements of S, a monoid under concatenation with the empty sequence as unit. A map $f\colon S \to M$ to a monoid extends uniquely to a homomorphism $W(S) \to M$, namely $(s_1, \ldots, s_n) \mapsto f(s_1) \cdots f(s_n)$. This gives an adjunction $W \dashv U$, where $U\colon \mathsf{Mon} \to \mathsf{Set}$ is the forgetful functor. Similarly, free groups, free abelian groups and free modules are left adjoints of forgetful functors (Chapters 7 and 8).

2. *Products and maps.* For a small set B, the functor $- \times B$ on Set is left adjoint to $(-)^B$: the bijection $\mathrm{Hom}(A \times B, C) \cong \mathrm{Hom}(A, C^B)$ of Exercise 3.9.1 is natural in A and C.

3. *Topology.* The forgetful functor $\mathsf{Top} \to \mathsf{Set}$ has a left adjoint (discrete topology) and a right adjoint (indiscrete topology).

Counterexample 6.10.6. The forgetful functor $U\colon \mathsf{Field} \to \mathsf{Set}$ has no left adjoint. A left adjoint L would preserve colimits by Theorem 6.10.4, in particular initial objects, so $L(\emptyset)$ would be an initial field. But an initial field would admit homomorphisms to $\mathbb{Q}$ and to $\mathbb{F}_2$, which is impossible by the argument of Counterexample 6.8.9.

6.11 Filtered colimits

Definition 6.11.1. A category $\mathcal{I}$ is *filtered* if it is nonempty, for all objects i, j there are an object k and morphisms $i \to k$ and $j \to k$, and for all morphisms $u, v\colon i \to j$ there is a morphism $w\colon j \to k$ with $w \circ u = w \circ v$. A *filtered colimit* is a colimit of a diagram whose shape is a small filtered category.

Example 6.11.2. A preordered set I is *directed* if it is nonempty and every two elements have a common upper bound. Viewed as a category (Example 6.2.9), a directed set is filtered, the third condition being automatic. For example $\mathbb{N}$ is directed, and the set of open neighbourhoods of a point in a topological space, ordered by reverse inclusion, is directed; colimits over it define stalks of sheaves (Chapter 25).

Lemma 6.11.3. *Let $\mathcal{I}$ be filtered.*

1. *For finitely many objects $i_1, \ldots, i_n$ there is an object k with morphisms $i_m \to k$.*

2. *For finitely many morphisms $u_1, \ldots, u_n\colon i \to j$ there is $w\colon j \to k$ with $wu_1 = wu_2 = \cdots = wu_n$.*

3. *For finitely many morphisms $u_m\colon i \to j_m$, $1 \le m \le n$, there are an object k and morphisms $w_m\colon j_m \to k$ with $w_1 u_1 = \cdots = w_n u_n$.*

Proof. (1) and (2) follow by induction on n from the definition; for (2), if $wu_1 = \cdots = wu_{n-1}$ with $w\colon j \to k$, choose $w'\colon k \to k'$ with $w'wu_{n-1} = w'wu_n$. (3) By (1) choose k' and $v_m\colon j_m \to k'$. The morphisms $v_m u_m\colon i \to k'$ are parallel, so by (2) there is $w\colon k' \to k$ with all $wv_m u_m$ equal; put $w_m = wv_m$. □

Proposition 6.11.4. *Let $\mathcal{I}$ be a small filtered category and $F\colon \mathcal{I} \to \mathsf{Set}$. On $\coprod_i F(i)$, the relation*

$$(i,x) \approx (j,y) \iff \text{there are } u\colon i \to k \text{ and } v\colon j \to k \text{ with } F(u)(x) = F(v)(y)$$

is an equivalence relation, and $\operatorname{colim} F = (\coprod_i F(i))/\!\approx$. *In particular every element of* $\operatorname{colim} F$ *is of the form $\gamma_i(x)$, and $\gamma_i(x) = \gamma_i(x')$ if and only if $F(u)(x) = F(u)(x')$ for some $u\colon i \to k$.*

Proof. Reflexivity and symmetry are clear. For transitivity, let $F(u)(x) = F(v)(y)$ with $u\colon i \to k$, $v\colon j \to k$, and $F(v')(y) = F(w')(z)$ with $v'\colon j \to k'$, $w'\colon l \to k'$. By Lemma 6.11.3(3) applied to v and v', there are $a\colon k \to m$ and $b\colon k' \to m$ with $av = bv'$. Then $F(au)(x) = F(av)(y) = F(bv')(y) = F(bw')(z)$. The relation $\approx$ contains the generating relation of Proposition 6.9.3 (take $v = \mathrm{id}$), and it is contained in every equivalence relation containing it, since $(i,x) \sim (k, F(u)(x)) = (k, F(v)(y)) \sim (j,y)$. So it is the smallest one. For the last statement, if $F(u)(x) = F(v)(x')$ with $u, v\colon i \to k$, choose w with $wu = wv$ by filteredness; then $F(wu)(x) = F(wu)(x')$. □

Theorem 6.11.5. *Let $\mathcal{I}$ be a small filtered category, $\mathcal{J}$ a category with finitely many morphisms, and $F\colon \mathcal{I} \times \mathcal{J} \to \mathsf{Set}$ a functor. Then the canonical map*

$$\kappa\colon \operatorname*{colim}_{i\in\mathcal{I}} \lim_{j\in\mathcal{J}} F(i,j) \longrightarrow \lim_{j\in\mathcal{J}} \operatorname*{colim}_{i\in\mathcal{I}} F(i,j)$$

is a bijection. That is, in Set *filtered colimits commute with finite limits.*

Proof. We use the descriptions of Propositions 6.8.5 and 6.11.4. An element of the left side is represented by some i and a family $(x_j)_j$ with $x_j \in F(i,j)$ compatible with all morphisms of $\mathcal{J}$; the map κ sends it to the family of classes $([(i,x_j)])_j$.

Injectivity. Let two elements of the left side be represented by $(x_j) \in \lim_j F(i,j)$ and $(y_j) \in \lim_j F(i',j)$. By Lemma 6.11.3(1) and the functoriality of the limit in i, we may assume $i = i'$. Suppose $[(i,x_j)] = [(i,y_j)]$ for all j. By Proposition 6.11.4, for each of the finitely many objects j there is $u_j\colon i \to k_j$ with $F(u_j,j)(x_j) = F(u_j,j)(y_j)$. By Lemma 6.11.3(3) there are $w_j\colon k_j \to k$ with all $w_j u_j$ equal to one $u\colon i \to k$. Then $F(u,j)(x_j) = F(u,j)(y_j)$ for all j, so the two families have the same image in $\lim_j F(k,j)$ and define the same element of the colimit.

Surjectivity. Let $(\xi_j)_j$ be an element of the right side. Each ξ_j is represented by some $x_j \in F(i_j,j)$. Using Lemma 6.11.3(1) and replacing each x_j by its image, we may assume all i_j equal to one i. For each morphism $a\colon j \to j'$ of $\mathcal{J}$, compatibility of (ξ_j) says that $F(i,a)(x_j)$ and $x_{j'}$ have the same class in $\operatorname{colim}_i F(i,j')$, so there is $u_a\colon i \to k_a$ with $F(u_a,j')(F(i,a)(x_j)) = F(u_a,j')(x_{j'})$. There are finitely many a; by Lemma 6.11.3(3) we find $w_a\colon k_a \to k$ with all $w_a u_a$ equal to one $u\colon i \to k$. Put $y_j = F(u,j)(x_j) \in F(k,j)$. For every $a\colon j \to j'$, $F(k,a)(y_j) = F(u,j')(F(i,a)(x_j)) = F(w_a,j')F(u_a,j')(F(i,a)(x_j)) = F(u,j')(x_{j'}) = y_{j'}$, using that F is a functor on $\mathcal{I} \times \mathcal{J}$. So (y_j) lies in $\lim_j F(k,j)$, and its class maps to $([(k,y_j)])_j = (\xi_j)_j$. □

Counterexample 6.11.6. Filtered colimits do not commute with infinite products in Set. Let $\mathcal{I} = \mathbb{N}$, let $\mathcal{J}$ be the discrete category on $\mathbb{N}$, and let $F(n,j) = \{0,1,\dots,n\}$ with the inclusions as transition maps. Then $\operatorname{colim}_n F(n,j) = \mathbb{N}$ for every j, so the right side is the set of all sequences of natural numbers, whereas the left side $\operatorname{colim}_n \prod_j \{0,\dots,n\}$ consists of the bounded sequences. The sequence $j \mapsto j$ is not in the image of κ.

Counterexample 6.11.7. Colimits that are not filtered do not commute with finite limits either. Take $\mathcal{I}$ discrete with two objects and $\mathcal{J}$ discrete with two objects, and $F(i,j) = \{0\}$ for all i, j. The left side is a coproduct of two products of one-element sets, with 2 elements, whereas the right side is a product of two coproducts of two one-element sets, with 4 elements.

6.12 Additive categories

Definition 6.12.1. A category $\mathcal{A}$ is *preadditive* if every set $\mathrm{Hom}(X, Y)$ has the structure of an abelian group, written additively, such that composition is bilinear: $(f + f') \circ g = f \circ g + f' \circ g$ and $h \circ (f + f') = h \circ f + h \circ f'$. A *zero object* is an object that is both initial and terminal. A preadditive category is *additive* if it has a zero object and binary products. A functor between preadditive categories is *additive* if the maps $\mathrm{Hom}(X, Y) \to \mathrm{Hom}(F(X), F(Y))$ are group homomorphisms.

Lemma 6.12.2. *Let $\mathcal{A}$ be preadditive and X_1, X_2, P objects with morphisms $i_m \colon X_m \to P$ and $p_m \colon P \to X_m$ such that*

$$p_1 i_1 = \mathrm{id}_{X_1}, \quad p_2 i_2 = \mathrm{id}_{X_2}, \quad p_2 i_1 = 0, \quad p_1 i_2 = 0, \quad i_1 p_1 + i_2 p_2 = \mathrm{id}_P.$$

Then (P, p_1, p_2) is a product and (P, i_1, i_2) is a coproduct of X_1 and X_2. Conversely, if $\mathcal{A}$ has a zero object and (P, p_1, p_2) is a product of X_1 and X_2, there are unique i_1, i_2 satisfying these equations.

Proof. Given $f_m \colon Y \to X_m$, the morphism $f = i_1 f_1 + i_2 f_2$ satisfies $p_m f = f_m$. If g also does, then $g = (i_1 p_1 + i_2 p_2) g = i_1 f_1 + i_2 f_2$. So P is a product; the coproduct statement is dual. Conversely, let $i_1 \colon X_1 \to P$ be the unique morphism with $p_1 i_1 = \mathrm{id}$ and $p_2 i_1 = 0$, and similarly i_2 (the zero morphism $0 \in \mathrm{Hom}(X, Y)$ exists since Hom sets are groups). Then $p_m(i_1 p_1 + i_2 p_2) = p_m$ for $m = 1, 2$, so $i_1 p_1 + i_2 p_2 = \mathrm{id}_P$ by the uniqueness in the universal property of the product. □

Definition 6.12.3. An object P with morphisms as in Lemma 6.12.2 is a *biproduct* or *direct sum* of X_1 and X_2, written $X_1 \oplus X_2$. In a preadditive category with a zero object, the *kernel* of $f \colon X \to Y$ is an equaliser of f and 0, and its *cokernel* is a coequaliser of f and 0.

Proposition 6.12.4. *Additive functors preserve biproducts and zero objects.*

Proof. The equations of Lemma 6.12.2 involve only composition, sums, identities and zero morphisms, all preserved by an additive functor F, so F sends a biproduct to a biproduct. An object Z is a zero object if and only if $\mathrm{id}_Z = 0$ (then every $\mathrm{Hom}(Z, Y)$ and $\mathrm{Hom}(Y, Z)$ is the zero group), and this is preserved by F. □

Example 6.12.5. The categories of abelian groups, of modules over a ring and of vector spaces over a field are additive, with the direct sum as biproduct (Chapter 8).

Counterexample 6.12.6. The category Set admits no preadditive structure: in a preadditive category every $\mathrm{Hom}(X, Y)$ is nonempty, since it contains 0, but $\mathrm{Hom}_{\mathsf{Set}}(\{0\}, \emptyset) = \emptyset$.

6.13 Exercises

Exercise 6.13.1. Show that a composition of faithful functors is faithful, and that a composition of full functors is full.

Solution. Let $F \colon \mathcal{C} \to \mathcal{D}$ and $G \colon \mathcal{D} \to \mathcal{E}$. The map $\mathrm{Hom}_{\mathcal{C}}(X, Y) \to \mathrm{Hom}_{\mathcal{E}}(GF(X), GF(Y))$ induced by $G \circ F$ is the composition of the maps induced by F and by G. A composition of injective maps is injective, and a composition of surjective maps is surjective. □

Exercise 6.13.2. Let $f : X \to Y$ be a morphism in a category. Show that if there is $r : Y \to X$ with $r \circ f = \mathrm{id}_X$, then f is a monomorphism, and if there is $s : Y \to X$ with $f \circ s = \mathrm{id}_Y$, then f is an epimorphism. Show that in Set every monomorphism with non-empty source has such an r. Show that the statement "every epimorphism in Set has such an s" is equivalent to the axiom of choice (for small sets).

Exercise 6.13.3. Let P and Q be preorders, viewed as categories, and let $F, G : P \to Q$ be functors. Show that there is a natural transformation $F \Rightarrow G$ if and only if $F(x) \leq G(x)$ for all $x \in P$, and that it is then unique.

Solution. Every set of morphisms of Q has at most one element, so a family $(\eta_x : F(x) \to G(x))_x$ exists if and only if $F(x) \leq G(x)$ for all x, it is unique if it exists, and every square of morphisms of Q commutes. □

Exercise 6.13.4. State and prove the analogue of Theorem 6.6.1 for functors $F : \mathcal{C} \to \mathsf{Set}$ and the functors h^X of Definition 6.4.4. (Hint: apply the theorem to $\mathcal{C}^{\mathrm{op}}$.)

Exercise 6.13.5. Suppose (X, ξ) and (X', ξ') both represent a functor $F : \mathcal{C}^{\mathrm{op}} \to \mathsf{Set}$. Show that there is a unique morphism $a : X \to X'$ with $F(a)(\xi') = \xi$, and that a is an isomorphism.

Exercise 6.13.6. Show that the inclusion $\mathbb{Z} \to \mathbb{Q}$ is an epimorphism in the category of rings, although it is not surjective.

Exercise 6.13.7. Show that in Set a morphism that is both a monomorphism and an epimorphism is an isomorphism, and that the same holds in the category of groups for monomorphisms that are surjective.

Exercise 6.13.8. Let P be a partially ordered set viewed as a category. Show that a product of a family of elements is a greatest lower bound, a coproduct is a least upper bound, and that every diagram in P has a limit if and only if every subset of P has a greatest lower bound.

Solution. A cone over a family (x_i) with vertex y exists if and only if $y \leq x_i$ for all i, and it is unique; a limit is a lower bound y such that every lower bound z satisfies $z \leq y$. Coproducts are dual. For a general diagram $F : \mathcal{I} \to P$ the cone condition only involves the objects, so a limit of F is a greatest lower bound of $\{F(i)\}$. □

Exercise 6.13.9. Let $F \dashv G$ with unit η and counit ε. Show that F is fully faithful if and only if η is a natural isomorphism, and that F is an equivalence if and only if both η and ε are natural isomorphisms. Conversely, show that every equivalence is part of an adjunction whose unit and counit are isomorphisms.

Exercise 6.13.10. Let $\mathcal{I}$, $\mathcal{J}$ be small and $F : \mathcal{I} \times \mathcal{J} \to \mathcal{C}$, where $\mathcal{C}$ has limits. Show that $\lim_i \lim_j F(i,j) \cong \lim_{(i,j)} F(i,j) \cong \lim_j \lim_i F(i,j)$.

Exercise 6.13.11. Show that a functor $G : \mathcal{D} \to \mathsf{Set}$ is representable (in the covariant sense of Exercise 6.13.4) if and only if it has a left adjoint F with $F(\{0\}) \cong X$ for some X, provided $\mathcal{D}$ has coproducts indexed by small sets. (Hint: $F(S) = \coprod_{s \in S} X$.)

Exercise 6.13.12. In an additive category, show that $f + g$ equals the composite $X \to X \oplus X \to Y \oplus Y \to Y$ of the diagonal, $f \oplus g$ and the codiagonal. Deduce that the abelian group structure on Hom sets of an additive category is determined by the category itself.

Part II

Algebra

Chapter 7

Groups

7.1 Introduction

Groups describe symmetry. This chapter develops the basic theory: subgroups, quotients and the isomorphism theorems, group actions and the Sylow theorems, symmetric and alternating groups, products, solvable and nilpotent groups, free groups and presentations, and the structure of finitely generated abelian groups. Groups appear throughout the project: as fundamental groups in topology (Chapter 19), as Galois groups (Chapter 9), as structure groups of vector bundles, and as Mumford–Tate groups of Hodge structures (Chapter 67).

References are [Lan02], [Rot95] and [DF04]; for free groups and amalgamated products see [Ser80] and [LS77].

Prerequisites. Chapter 3 (Set Theory), Chapter 4 (Number Systems) and Chapter 6 (Categories).

On the way to the Hodge conjecture. Only the basic notions are needed: groups, homomorphisms, cosets and quotients (Sections 7.2, 7.3, 7.4), and group actions (Section 7.6). The Sylow theorems, symmetric and solvable groups, free groups and the structure of abelian groups can be postponed; presentations reappear with the fundamental group in Chapter 19.

7.2 Groups and homomorphisms

Definition 7.2.1. A *group* is a set G together with a map $G \times G \to G$, called the *group law* and written $(a, b) \mapsto a \cdot b$, and an element $e \in G$, such that for all $a, b, c \in G$:

1. (associativity) $(a \cdot b) \cdot c = a \cdot (b \cdot c)$;
2. (neutral element) $e \cdot a = a \cdot e = a$;
3. (inverses) there is an element $a' \in G$ with $a \cdot a' = a' \cdot a = e$.

The group is *abelian* if $a \cdot b = b \cdot a$ for all $a, b \in G$. The *order* of G is its cardinality $|G|$.

Notation 7.2.2. Two notations are used for the group law.

- *Multiplicative notation*, used for all groups: the group law is written $a \cdot b$ or simply ab, the neutral element e (or 1), the inverse of a is written a^{-1} (it is unique by Lemma 7.2.3), and a^n denotes the n-th power (Lemma 7.2.9).
- *Additive notation*, used only for abelian groups: the group law is written $a + b$, the neutral element 0, the inverse $-a$, and na the n-th multiple.

Every statement in multiplicative notation applies to abelian groups written additively through the dictionary $ab \leftrightarrow a+b$, $e \leftrightarrow 0$, $a^{-1} \leftrightarrow -a$, $a^n \leftrightarrow na$. General results in this chapter are stated multiplicatively. For groups arising from a familiar structure we keep the familiar symbol: $+$ for $(\mathbb{Z},+)$, multiplication for $\mathbb{Q}^\times$ or for invertible matrices, and composition $\circ$ (written as juxtaposition) for groups of bijections. The symbol $*$ never denotes a group law; $G_1 * G_2$ is the free product of Definition 7.10.6. When the group law has to be named, we write $(G,\cdot)$ or $(G,+)$.

Lemma 7.2.3. *In a group the neutral element and inverses are unique,* $(ab)^{-1} = b^{-1}a^{-1}$, $(a^{-1})^{-1} = a$, *and* $ab = ac$ *or* $ba = ca$ *implies* $b = c$.

Proof. If e' is also neutral, $e = ee' = e'$. If b and c are inverses of a, then $b = b(ac) = (ba)c = c$; we write a^{-1} for the inverse. The element $b^{-1}a^{-1}$ is inverse to ab, and a is inverse to a^{-1}. Cancellation follows by multiplying with a^{-1}. □

Example 7.2.4.

1. $(\mathbb{Z},+)$, $(\mathbb{Q},+)$, $(\mathbb{R},+)$ and $(\mathbb{C},+)$ are abelian groups, as are $\mathbb{Q}^\times = \mathbb{Q}\setminus\{0\}$, $\mathbb{R}^\times$ and $\mathbb{C}^\times$ under multiplication. More generally, for a commutative ring R the invertible elements form a group $R^\times$.
2. For a set X, the bijections $X \to X$ form the *symmetric group* $\mathrm{Sym}(X)$ under composition. We write $S_n = \mathrm{Sym}(\{1,\dots,n\})$.
3. For a field k, the invertible $n \times n$ matrices form the group $\mathrm{GL}_n(k)$ (Chapter 11).
4. The *trivial group* has one element.
5. A group with one object as a category (Example 6.2.8) is a category with one object in which every morphism is an isomorphism.

Definition 7.2.5. A *homomorphism* of groups is a map $f\colon G \to H$ with $f(ab) = f(a)f(b)$ for all $a,b \in G$. Its *kernel* is $\ker f = \{a \in G : f(a) = e\}$ and its *image* is $\mathrm{im}\, f = f[G]$. An *isomorphism* is a bijective homomorphism; an *automorphism* of G is an isomorphism $G \to G$, and they form a group $\mathrm{Aut}(G)$. Small groups and homomorphisms form a locally small category Grp, with the full subcategory Ab of abelian groups.

Lemma 7.2.6. *A homomorphism* f *satisfies* $f(e) = e$ *and* $f(a^{-1}) = f(a)^{-1}$*; it is injective if and only if* $\ker f = \{e\}$*; and the inverse of a bijective homomorphism is a homomorphism.*

Proof. $f(e) = f(e)f(e)$ gives $f(e) = e$ by cancellation, and then $f(a)f(a^{-1}) = f(e) = e$. If $\ker f$ is trivial and $f(a) = f(b)$, then $f(ab^{-1}) = e$, so $a = b$. If f is bijective with inverse g, then $f(g(x)g(y)) = xy$, so $g(xy) = g(x)g(y)$. □

Definition 7.2.7. A *subgroup* of G is a subset H containing e with $ab \in H$ and $a^{-1} \in H$ for all $a,b \in H$; it is a group with the restricted operation. We write $H \le G$. For a subset $S \subseteq G$, the *subgroup generated by* S, written $\langle S\rangle$, is the intersection of all subgroups containing S.

Lemma 7.2.8. *The subgroup* $\langle S\rangle$ *consists of all finite products* $s_1^{\epsilon_1}\cdots s_k^{\epsilon_k}$ *with* $k \ge 0$, $s_i \in S$ *and* $\epsilon_i \in \{1,-1\}$ *(the empty product being* e*). Kernels and images of homomorphisms are subgroups.*

Proof. The set of such products contains S and is closed under products and inverses (Lemma 7.2.3), so it contains $\langle S\rangle$; and every subgroup containing S contains all such products. The second statement follows from Lemma 7.2.6. □

Lemma 7.2.9. *Let* G *be a group and* $g \in G$*. There is a unique homomorphism* $\mathbb{Z} \to G$ *sending* 1 *to* g*; we write* $n \mapsto g^n$*. Thus* $g^{m+n} = g^m g^n$ *and* $(g^m)^n = g^{mn}$ *for all* $m,n \in \mathbb{Z}$.

Proof. Uniqueness is clear since 1 generates $\mathbb{Z}$. For existence define g^n for $n \in \mathbb{N}$ by recursion ($g^0 = e$, $g^{n+1} = g^n g$) and put $g^{-n} = (g^{-1})^n$. One checks $g^{m+1} = g^m g$ for all $m \in \mathbb{Z}$ (for $m = -n - 1 < 0$ this reads $(g^{-1})^n = (g^{-1})^{n+1} g$, which holds since $g^{-1} g = e$), and then $g^{m+n} = g^m g^n$ follows by induction on $n \geq 0$ and on $-n \geq 0$. The last formula holds because $n \mapsto g^{mn}$ and $n \mapsto (g^m)^n$ are both homomorphisms sending 1 to g^m. □

Proposition 7.2.10. *Every subgroup of $\mathbb{Z}$ is of the form $n\mathbb{Z} = \{nk : k \in \mathbb{Z}\}$ for a unique $n \in \mathbb{N}$.*

Proof. Let $H \leq \mathbb{Z}$. If $H = \{0\}$ take $n = 0$. Otherwise H contains a positive element, and we let n be the least one. Then $n\mathbb{Z} \subseteq H$, and for $h \in H$, division with remainder (Theorem 4.5.2) gives $h = qn + r$ with $0 \leq r < n$ and $r = h - qn \in H$, so $r = 0$. The number n is the least positive element of $n\mathbb{Z}$, hence unique. □

Definition 7.2.11. The *order* of $g \in G$ is the least $n \geq 1$ with $g^n = e$ if it exists, and ∞ otherwise. By Proposition 7.2.10, the kernel of $n \mapsto g^n$ is $\mathrm{ord}(g)\mathbb{Z}$ (with $\infty\mathbb{Z} := \{0\}$). A group is *cyclic* if it is generated by one element.

7.3 Cosets and Lagrange's theorem

Definition 7.3.1. Let $H \leq G$. A *left coset* of H is a set $gH = \{gh : h \in H\}$, and a right coset is a set Hg. The set of left cosets is G/H, and the *index* of H is $[G : H] = |G/H|$.

Lemma 7.3.2. *The left cosets of H are the classes of the equivalence relation $a \sim b \iff a^{-1}b \in H$; hence they partition G. Each left coset is in bijection with H, and $gH \mapsto Hg^{-1}$ is a bijection from left to right cosets.*

Proof. The relation is an equivalence relation because H is a subgroup, and the class of a is aH. The map $h \mapsto gh$ is a bijection $H \to gH$. Finally $aH = bH$ iff $a^{-1}b \in H$ iff $(a^{-1}b)^{-1} = b^{-1}a \in H$ iff $Ha^{-1} = Hb^{-1}$. □

Theorem 7.3.3 (Lagrange)**.** *Let G be finite and $H \leq G$. Then $|G| = [G : H] \cdot |H|$. In particular the order of H divides the order of G, and the order of every element divides $|G|$, so $g^{|G|} = e$ for all $g \in G$.*

Proof. By Lemma 7.3.2, G is the disjoint union of $[G : H]$ sets of size $|H|$. The subgroup $\langle g \rangle$ has order $\mathrm{ord}(g)$, since $g^0, \ldots, g^{\mathrm{ord}(g)-1}$ are distinct and every power g^n equals g^r with r the remainder of n. □

Corollary 7.3.4. *A group of prime order p is cyclic, generated by any element $\neq e$.*

Proof. If $g \neq e$, then $\mathrm{ord}(g) > 1$ divides p, so it equals p, and $\langle g \rangle = G$. □

Corollary 7.3.5 (Euler, Fermat, Wilson)**.** *Let $n \geq 2$, and write $a \equiv b \pmod{n}$ if $n \mid a - b$. Let U_n be the set of residue classes modulo n of the integers a with $\gcd(a, n) = 1$, and $\varphi(n) = |U_n|$ the number of $0 \leq a < n$ with $\gcd(a, n) = 1$.*

1. *Multiplication of representatives makes U_n an abelian group, with identity the class of 1.*
2. *(Euler) $a^{\varphi(n)} \equiv 1 \pmod{n}$ whenever $\gcd(a, n) = 1$.*
3. *(Fermat) If p is prime and $p \nmid a$, then $a^{p-1} \equiv 1 \pmod{p}$; and $a^p \equiv a \pmod{p}$ for every integer a.*
4. *(Wilson) If p is prime, then $(p - 1)! \equiv -1 \pmod{p}$.*

Proof. (1) If $a \equiv a'$ and $b \equiv b'$, then $ab - a'b' = a(b - b') + b'(a - a')$ is divisible by n, so the product of classes is well defined; it is associative and commutative because multiplication of integers is. If $\gcd(a, n) = \gcd(b, n) = 1$ then $\gcd(ab, n) = 1$: a prime dividing n and ab divides a or b (Lemma 4.5.4). By Bézout (Theorem 4.5.3), $\gcd(a, n) = 1$ gives $ax + ny = 1$, so the class of x, which is again coprime to n, is an inverse of the class of a.

(2) By Theorem 7.3.3 applied to the group U_n of order $\varphi(n)$.

(3) For $n = p$ prime, every a with $0 < a < p$ is coprime to p, so $\varphi(p) = p - 1$ and (2) applies. Multiplying by a gives $a^p \equiv a$, which also holds trivially when $p \mid a$.

(4) An element x of U_p is its own inverse exactly when $p \mid x^2 - 1 = (x - 1)(x + 1)$, that is, by Lemma 4.5.4, when $x \equiv \pm 1$. The remaining elements of U_p fall into pairs $\{x, x^{-1}\}$ with product 1. So the product of all elements of U_p, which is the class of $(p - 1)!$, is the class of $1 \cdot (-1) = -1$ (for $p = 2$, $1 \equiv -1$ and the statement is clear). □

Example 7.3.6. $\varphi(12) = 4$, with $U_{12} = \{1, 5, 7, 11\}$, and every element squares to 1; so U_{12} is not cyclic, although U_{12} has order 4 and $U_5 = \{1, 2, 3, 4\}$, also of order 4, is cyclic, generated by 2 ($2^2 = 4$, $2^3 = 8 \equiv 3$, $2^4 = 16 \equiv 1$). Fermat's little theorem gives, for instance, $2^{100} = (2^{10})^{10} \equiv 1 \pmod{11}$. Its converse fails: $561 = 3 \cdot 11 \cdot 17$ is not prime, yet $a^{560} \equiv 1 \pmod{561}$ for all a coprime to 561, because 2, 10 and 16 divide 560, so Fermat's theorem gives the congruence modulo 3, 11 and 17, hence modulo their product, the three primes being distinct (Theorem 4.5.5). Such numbers are called *Carmichael numbers*.

Proposition 7.3.7. *If $K \leq H \leq G$ and the indices are finite, then $[G : K] = [G : H][H : K]$.*

Proof. Let (g_i) represent the left cosets of H in G and (h_j) those of K in H. Then the $g_i h_j K$ are the left cosets of K in G, and they are distinct: $G = \bigsqcup_i g_i H = \bigsqcup_i \bigsqcup_j g_i h_j K$. □

7.4 Normal subgroups and quotients

Definition 7.4.1. A subgroup $N \leq G$ is *normal*, written $N \trianglelefteq G$, if $gNg^{-1} = N$ for all $g \in G$, equivalently $gN = Ng$ for all g. A group $G \neq \{e\}$ is *simple* if its only normal subgroups are $\{e\}$ and G.

Lemma 7.4.2. *Kernels of homomorphisms are normal. Every subgroup of an abelian group is normal. A subgroup of index 2 is normal.*

Proof. If $f(n) = e$ then $f(gng^{-1}) = f(g)f(g)^{-1} = e$. The second claim is clear. If $[G : H] = 2$, then for $g \notin H$ both gH and Hg are the complement of H. □

Theorem 7.4.3. *Let $N \trianglelefteq G$. The rule $(aN)(bN) = abN$ is a well-defined operation making G/N a group, the* quotient group, *and the projection $\pi : G \to G/N$ is a surjective homomorphism with kernel N. If $f : G \to H$ is a homomorphism with $N \subseteq \ker f$, there is a unique homomorphism $\bar{f} : G/N \to H$ with $\bar{f} \circ \pi = f$.*

Proof. If $aN = a'N$ and $bN = b'N$, write $a' = an, b' = bm$. Then $a'b' = anbm = ab(b^{-1}nb)m \in abN$ since N is normal. The group axioms follow from those of G, with neutral element N and $(aN)^{-1} = a^{-1}N$. Clearly π is a surjective homomorphism, and $\pi(a) = N$ iff $a \in N$. If $N \subseteq \ker f$ then f is constant on cosets, and $\bar{f}$ exists and is unique by Proposition 3.3.9; it is a homomorphism because π is surjective. □

Theorem 7.4.4 (Isomorphism theorems).

1. *If $f : G \to H$ is a homomorphism, $\bar{f} : G/\ker f \to \operatorname{im} f$ is an isomorphism.*
2. *If $H \leq G$ and $N \trianglelefteq G$, then HN is a subgroup, $N \trianglelefteq HN$, $H \cap N \trianglelefteq H$, and $H/(H \cap N) \cong HN/N$.*

3. *If $N \leq M$ are normal subgroups of G, then $M/N \trianglelefteq G/N$ and $(G/N)/(M/N) \cong G/M$.*

4. *(Correspondence theorem) If $N \trianglelefteq G$, then $K \mapsto K/N$ is a bijection from the set of subgroups of G containing N to the set of subgroups of G/N, preserving inclusions, normality and indices.*

Proof. (1) $\bar{f}$ is surjective onto $\operatorname{im} f$ and has trivial kernel. (2) $HN = NH$ because $hN = Nh$, so HN is closed under products and inverses. The composite $H \to HN \to HN/N$ is surjective, since $hnN = hN$, with kernel $H \cap N$; apply (1). (3) The map $G/N \to G/M$, $gN \mapsto gM$, is a well-defined surjective homomorphism (Theorem 7.4.3) with kernel M/N; apply (1). (4) The inverse map sends $\bar{K} \leq G/N$ to $\pi^{-1}[\bar{K}]$; since π is surjective, $\pi[\pi^{-1}[\bar{K}]] = \bar{K}$, and $\pi^{-1}[\pi[K]] = KN = K$ when $N \subseteq K$. Normality is preserved because π is surjective, and $gK \mapsto (gN)(K/N)$ is a bijection $G/K \to (G/N)/(K/N)$. □

Example 7.4.5. For $n \geq 1$, the quotient $\mathbb{Z}/n\mathbb{Z}$ is a cyclic group of order n, with elements the classes of $0, 1, \ldots, n-1$. If $G = \langle g \rangle$ is cyclic, the homomorphism $\mathbb{Z} \to G$, $k \mapsto g^k$ is surjective with kernel $\operatorname{ord}(g)\mathbb{Z}$, so $G \cong \mathbb{Z}$ if g has infinite order and $G \cong \mathbb{Z}/n\mathbb{Z}$ if $\operatorname{ord}(g) = n$. Thus a cyclic group is determined up to isomorphism by its order. By the correspondence theorem the subgroups of $\mathbb{Z}/n\mathbb{Z}$ are the $d\mathbb{Z}/n\mathbb{Z}$ for $d \mid n$, one for each divisor.

Definition 7.4.6. The *center* of G is $Z(G) = \{z \in G : zg = gz \text{ for all } g\}$. For $g \in G$, *conjugation* $c_g(x) = gxg^{-1}$ is an automorphism; automorphisms of this form are *inner*. The *centraliser* of x is $C_G(x) = \{g : gx = xg\}$ and the *normaliser* of $H \leq G$ is $N_G(H) = \{g : gHg^{-1} = H\}$.

Lemma 7.4.7. *$Z(G)$ is a normal subgroup, and $g \mapsto c_g$ is a homomorphism $G \to \operatorname{Aut}(G)$ with kernel $Z(G)$. If $G/Z(G)$ is cyclic, then G is abelian.*

Proof. $c_{gh} = c_g \circ c_h$, and $c_g = \mathrm{id}$ iff $g \in Z(G)$. If $G/Z(G)$ is generated by $gZ(G)$, every element of G is $g^k z$ with $z \in Z(G)$, and such elements commute with each other. □

7.5 Products

Proposition 7.5.1. *For a family of groups $(G_i)_{i \in I}$, the set $\prod_i G_i$ with the componentwise operation is a group, and with the projections it is a product in* Grp *(Example 6.8.3). Let $N, M \trianglelefteq G$ with $N \cap M = \{e\}$ and $NM = G$. Then $nm = mn$ for $n \in N$, $m \in M$, and $N \times M \to G$, $(n, m) \mapsto nm$, is an isomorphism.*

Proof. The first statement is clear. For $n \in N$ and $m \in M$, the commutator $nmn^{-1}m^{-1}$ lies in N (as $mn^{-1}m^{-1} \in N$) and in M (as $nmn^{-1} \in M$), hence is e. So the map is a homomorphism; it is surjective since $NM = G$, and injective since $nm = e$ implies $n = m^{-1} \in N \cap M$. □

Definition 7.5.2. Let N and H be groups and $\varphi \colon H \to \operatorname{Aut}(N)$, $h \mapsto \varphi_h$, a homomorphism. The *semidirect product* $N \rtimes_\varphi H$ is the set $N \times H$ with the operation $(n, h)(n', h') = (n\varphi_h(n'), hh')$.

Proposition 7.5.3. *$N \rtimes_\varphi H$ is a group, in which $N \times \{e\}$ is a normal subgroup isomorphic to N, $\{e\} \times H$ is a subgroup isomorphic to H, and $(e, h)(n, e)(e, h)^{-1} = (\varphi_h(n), e)$. Conversely, if G is a group with $N \trianglelefteq G$ and $H \leq G$ such that $N \cap H = \{e\}$ and $NH = G$, then $(n, h) \mapsto nh$ is an isomorphism $N \rtimes_\varphi H \to G$, where $\varphi_h(n) = hnh^{-1}$.*

Proof. Associativity: $((n, h)(n', h'))(n'', h'') = (n\varphi_h(n')\varphi_{hh'}(n''), hh'h'')$ and $(n, h)((n', h')(n'', h'')) = (n\varphi_h(n'\varphi_{h'}(n'')), hh'h'')$ agree since φ is a homomorphism into $\operatorname{Aut}(N)$. The neutral element is (e, e) and $(n, h)^{-1} = (\varphi_{h^{-1}}(n^{-1}), h^{-1})$. The projection $(n, h) \mapsto h$ is a homomorphism with kernel $N \times \{e\}$, and the conjugation formula is a direct computation. For the converse, every $g \in G$ is uniquely nh (if $nh = n'h'$ then $n'^{-1}n = h'h^{-1} \in N \cap H$), and $nh \cdot n'h' = n(hn'h^{-1})hh'$, which is the product rule. □

Example 7.5.4. For $n \geq 3$ let $\varphi\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/n\mathbb{Z})$ send the generator to $x \mapsto -x$. The group $D_n = \mathbb{Z}/n\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$ of order $2n$ is the *dihedral group*; it is the group of symmetries of a regular n-gon (rotations and reflections). It is not abelian, since $(0,1)(1,0) = (-1,1) \neq (1,1) = (1,0)(0,1)$.

7.6 Group actions

Definition 7.6.1. An *action* of a group G on a set X is a map $G \times X \to X$, $(g,x) \mapsto gx$, with $ex = x$ and $g(hx) = (gh)x$; equivalently a homomorphism $G \to \mathrm{Sym}(X)$. The *orbit* of x is $Gx = \{gx : g \in G\}$, its *stabiliser* is $G_x = \{g : gx = x\}$, and $X^G = \{x : gx = x \text{ for all } g\}$ is the set of *fixed points*. The action is *transitive* if there is only one orbit, and *free* if all stabilisers are trivial.

Theorem 7.6.2 (Orbit–stabiliser)**.** *For an action of G on X and $x \in X$, the stabiliser G_x is a subgroup and $gG_x \mapsto gx$ is a bijection $G/G_x \to Gx$. In particular $|Gx| = [G : G_x]$, and the orbits partition X.*

Proof. $gG_x = hG_x$ iff $h^{-1}g \in G_x$ iff $gx = hx$, so the map is well defined and injective; it is surjective by definition. The relation "$y \in Gx$" is an equivalence relation since G is a group. □

Example 7.6.3.

1. G acts on itself by left multiplication, freely and transitively. This gives an injective homomorphism $G \to \mathrm{Sym}(G)$ (*Cayley's theorem*): every group is isomorphic to a group of permutations.
2. G acts on itself by conjugation; the orbits are the *conjugacy classes* and $G_x = C_G(x)$.
3. G acts on the set of its subgroups by conjugation, with stabiliser $N_G(H)$; so the number of conjugates of H is $[G : N_G(H)]$.
4. If $H \leq G$, then G acts transitively on G/H by $g(aH) = gaH$.

Corollary 7.6.4 (Class equation)**.** *Let G be finite and let $x_1, \ldots, x_r$ represent the conjugacy classes with more than one element. Then $|G| = |Z(G)| + \sum_{i=1}^{r} [G : C_G(x_i)]$.*

Proof. The conjugacy classes partition G; the one-element classes are the elements of $Z(G)$, and the class of x_i has $[G : C_G(x_i)]$ elements by Theorem 7.6.2. □

Definition 7.6.5. Let p be a prime. A *p-group* is a finite group whose order is a power of p.

Lemma 7.6.6. *Let a p-group P act on a finite set X. Then $|X| \equiv |X^P| \pmod{p}$.*

Proof. Each orbit that is not a fixed point has size $[P : P_x] > 1$, a divisor of $|P|$, hence divisible by p. □

Proposition 7.6.7. *A nontrivial p-group has nontrivial center. Every group of order p^2 is abelian.*

Proof. Apply Lemma 7.6.6 to the conjugation action: $|Z(G)| \equiv |G| \equiv 0 \pmod{p}$ and $e \in Z(G)$, so $|Z(G)| \geq p$. If $|G| = p^2$, then $|G/Z(G)| \in \{1, p\}$, so $G/Z(G)$ is cyclic (Corollary 7.3.4), and G is abelian by Lemma 7.4.7. □

Theorem 7.6.8 (Cauchy)**.** *If a prime p divides the order of a finite group G, then G has an element of order p.*

Proof. Let $X = \{(g_1, \ldots, g_p) \in G^p : g_1 g_2 \cdots g_p = e\}$. Since g_p is determined by the others, $|X| = |G|^{p-1} \equiv 0 \pmod{p}$. The group $\mathbb{Z}/p\mathbb{Z}$ acts on X by cyclic rotation: if $g_1 \cdots g_p = e$ then $g_2 \cdots g_p g_1 = g_1^{-1}(g_1 \cdots g_p)g_1 = e$. The fixed points are the tuples $(g, \ldots, g)$ with $g^p = e$. By Lemma 7.6.6 their number is divisible by p, and $(e, \ldots, e)$ is one of them, so there is a fixed point with $g \neq e$. □

7.7 The Sylow theorems

Definition 7.7.1. Let G be finite and $|G| = p^a m$ with p prime and $p \nmid m$. A *Sylow p-subgroup* of G is a subgroup of order p^a. We write $\mathrm{Syl}_p(G)$ for the set of them and $n_p = |\mathrm{Syl}_p(G)|$.

Theorem 7.7.2 (Sylow)**.** *Let G be a finite group, p a prime and $|G| = p^a m$ with $p \nmid m$.*

1. *Sylow p-subgroups exist.*
2. *Every p-subgroup of G is contained in a Sylow p-subgroup, and any two Sylow p-subgroups are conjugate.*
3. *n_p divides m and $n_p \equiv 1 \pmod{p}$.*

Proof. (1) By induction on $|G|$; if $a = 0$ there is nothing to prove. Suppose $p \mid |Z(G)|$. By Theorem 7.6.8 there is $z \in Z(G)$ of order p; $N = \langle z \rangle$ is normal, and G/N has order $p^{a-1}m$, so by induction it has a subgroup of order p^{a-1}, whose preimage in G has order p^a. Suppose $p \nmid |Z(G)|$. In the class equation (Corollary 7.6.4) the left side is divisible by p, so some $[G : C_G(x_i)]$ is not divisible by p. Then $C_G(x_i)$ is a proper subgroup of order divisible by p^a, and by induction it contains a subgroup of order p^a.

(2) Let P be a Sylow p-subgroup and Q a p-subgroup. Let Q act on G/P by left multiplication. Since $|G/P| = m \not\equiv 0 \pmod{p}$, Lemma 7.6.6 gives a fixed point gP. Then $QgP = gP$, so $g^{-1}Qg \subseteq P$ and $Q \subseteq gPg^{-1}$, which is a Sylow p-subgroup. If Q is itself Sylow, then $Q = gPg^{-1}$ by comparing orders.

(3) By (2), G acts transitively by conjugation on $\mathrm{Syl}_p(G)$, so $n_p = [G : N_G(P)]$, which divides $[G : P] = m$ since $P \leq N_G(P)$ (Proposition 7.3.7). Let P act on $\mathrm{Syl}_p(G)$ by conjugation. If Q is a fixed point, then $P \leq N_G(Q)$, so P and Q are Sylow p-subgroups of $N_G(Q)$, hence conjugate in $N_G(Q)$ by (2); as Q is normal in $N_G(Q)$, $P = Q$. So P is the only fixed point, and $n_p \equiv 1 \pmod{p}$ by Lemma 7.6.6. □

Corollary 7.7.3. *A Sylow p-subgroup is normal if and only if $n_p = 1$.*

Proof. By Theorem 7.7.2(2) the Sylow p-subgroups are the conjugates of one of them. □

Example 7.7.4. Every group G of order 15 is cyclic. Indeed n_3 divides 5 and is 1 modulo 3, so $n_3 = 1$; similarly $n_5 = 1$. The Sylow subgroups P_3, P_5 are normal, cyclic of prime order, and $P_3 \cap P_5 = \{e\}$ by Lagrange. Then $|P_3P_5| = 15$ (the map $P_3 \times P_5 \to G$ is injective), so $G \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$ by Proposition 7.5.1, and the element $(1, 1)$ has order 15.

7.8 Symmetric and alternating groups

Definition 7.8.1. Let $n \geq 1$. For distinct $a_1, \ldots, a_k \in \{1, \ldots, n\}$, the *cycle* $(a_1\, a_2 \cdots a_k) \in S_n$ sends a_i to a_{i+1} for $i < k$, a_k to a_1, and fixes all other points. A cycle of length 2 is a *transposition*. Two cycles are *disjoint* if they move disjoint sets of points. Products in S_n are compositions, applied from right to left.

Proposition 7.8.2. *Every $\sigma \in S_n$ is a product of disjoint cycles of length ≥ 2, uniquely up to order; disjoint cycles commute. Every element of S_n is a product of transpositions. For $\tau \in S_n$, $\tau(a_1 \cdots a_k)\tau^{-1} = (\tau(a_1) \cdots \tau(a_k))$, so two permutations are conjugate if and only if they have the same cycle lengths.*

Proof. The orbits of $\langle\sigma\rangle$ on $\{1,\dots,n\}$ partition it; on an orbit $\{a,\sigma(a),\dots,\sigma^{k-1}(a)\}$ of size k, σ acts as the cycle $(a\,\sigma(a)\cdots\sigma^{k-1}(a))$, and σ is the product of these cycles for the orbits of size ≥ 2. Conversely the cycles in any such decomposition must be the orbits, which gives uniqueness. Disjoint cycles commute since they act on disjoint sets. We have $(a_1\cdots a_k)=(a_1\,a_k)(a_1\,a_{k-1})\cdots(a_1\,a_2)$, as one checks by evaluating both sides. The conjugation formula follows by evaluating both sides at $\tau(a_i)$ and at points not of this form. If σ and σ' have the same cycle lengths, a bijection matching their cycles gives τ with $\tau\sigma\tau^{-1}=\sigma'$. □

Proposition 7.8.3. *There is a unique homomorphism* $\operatorname{sgn}\colon S_n\to\{1,-1\}$ *sending every transposition to* -1 *(for* $n\geq 2$*). It is given by* $\operatorname{sgn}(\sigma)=\prod_{1\leq i<j\leq n}\frac{\sigma(j)-\sigma(i)}{j-i}$.

Proof. For $\sigma\in S_n$ let $s(\sigma)$ be the product in the statement, a rational number. The factors $\sigma(j)-\sigma(i)$ run, up to sign, over all differences $j-i$ with $i<j$, so $s(\sigma)=\pm 1$. For $\sigma,\tau\in S_n$,

$$s(\sigma\tau)=\prod_{i<j}\frac{\sigma(\tau(j))-\sigma(\tau(i))}{\tau(j)-\tau(i)}\cdot\prod_{i<j}\frac{\tau(j)-\tau(i)}{j-i}.$$

The expression $\frac{\sigma(b)-\sigma(a)}{b-a}$ is symmetric in a and b, and $\{\tau(i),\tau(j)\}$ runs over all two-element subsets as $\{i,j\}$ does; so the first product is $s(\sigma)$, and s is a homomorphism. For the transposition $(1\,2)$, the only factor that is negative is the one with $(i,j)=(1,2)$, so $s((1\,2))=-1$. All transpositions are conjugate by Proposition 7.8.2, hence have sign -1. Uniqueness holds because transpositions generate S_n. □

Definition 7.8.4. The *alternating group* A_n is the kernel of sgn. Permutations in A_n are *even*. For $n\geq 2$, $[S_n:A_n]=2$.

Lemma 7.8.5. *For* $n\geq 3$*, the group* A_n *is generated by the* 3*-cycles. For* $n\geq 5$*, any two* 3*-cycles are conjugate in* A_n.

Proof. A 3-cycle is even, being a product of two transpositions. Every even permutation is a product of an even number of transpositions, and for distinct a,b,c,d we have $(a\,b)(a\,c)=(a\,c\,b)$ and $(a\,b)(c\,d)=(a\,b\,c)(b\,c\,d)$, as one checks by evaluation. For the second claim, two 3-cycles $(a\,b\,c)$ and $(a'\,b'\,c')$ are conjugate by some $\tau\in S_n$. If τ is odd, choose $d,e\notin\{a,b,c\}$ distinct (possible since $n\geq 5$); then $\tau(d\,e)$ is even and also conjugates $(a\,b\,c)$ to $(a'\,b'\,c')$, because $(d\,e)$ commutes with $(a\,b\,c)$. □

Theorem 7.8.6. *For* $n\geq 5$ *the group* A_n *is simple.*

Proof. Let $N\trianglelefteq A_n$ with $N\neq\{e\}$. By Lemma 7.8.5 it suffices to show that N contains a 3-cycle. Choose $\sigma\in N\setminus\{e\}$ with the largest possible number of fixed points. For $\rho\in A_n$, the element $\tau=(\rho\sigma\rho^{-1})\sigma^{-1}$ lies in N.

Suppose σ moves exactly 4 points. Being even, it is then of the form $(a\,b)(c\,d)$. Choose $e\notin\{a,b,c,d\}$ and $\rho=(c\,d\,e)$. Then $\rho\sigma\rho^{-1}=(a\,b)(d\,e)$ and $\tau=(a\,b)(d\,e)(a\,b)(c\,d)=(d\,e)(c\,d)=(c\,e\,d)$, a 3-cycle in N.

Suppose σ moves at least 5 points. If σ has a cycle of length ≥ 3, write it as $(a\,b\,c\cdots)$ and choose further points d,e moved by σ, distinct from a,b,c. Otherwise σ is a product of at least three disjoint transpositions, and we write $\sigma=(a\,b)(c\,d)(e\,f)\cdots$. In both cases let $\rho=(c\,d\,e)$. Every point fixed by σ is fixed by ρ, hence by τ; and $\tau(\sigma(x))=\rho\sigma\rho^{-1}(x)$. In the first case $\tau(b)=\tau(\sigma(a))=\rho(\sigma(a))=\rho(b)=b$, and $\tau(c)=\tau(\sigma(b))=\rho(\sigma(b))=\rho(c)=d\neq c$. In the second case $\tau(b)=\rho\sigma(a)=b$, $\tau(a)=\rho\sigma(b)=a$, and $\tau(d)=\tau(\sigma(c))=\rho\sigma\rho^{-1}(c)=\rho(\sigma(e))=\rho(f)=f\neq d$. In both cases $\tau\neq e$, τ fixes all points fixed by σ and at least one point moved by σ, contradicting the choice of σ. So this case does not occur. The remaining possibility is that σ moves exactly 3 points (an even permutation cannot move exactly 2), and then σ is a 3-cycle. In all cases N contains a 3-cycle. □

Counterexample 7.8.7. The converse of Lagrange's theorem is false: A_4 has order 12 but no subgroup of order 6. Such a subgroup H would have index 2, so $g^2 \in H$ for all $g \in A_4$ (as G/H has order 2). But every 3-cycle is a square: $(a\,b\,c) = (a\,c\,b)^2$. So H would contain the eight 3-cycles of A_4.

Counterexample 7.8.8. Normality is not transitive. In A_4, the subgroup $V = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\}$ is normal, being a union of conjugacy classes by Proposition 7.8.2. Its subgroup $K = \{e, (1\,2)(3\,4)\}$ is normal in the abelian group V. But $(1\,2\,3)(1\,2)(3\,4)(1\,2\,3)^{-1} = (2\,3)(1\,4) \notin K$, so K is not normal in A_4.

7.9 Solvable and nilpotent groups

Definition 7.9.1. The *commutator* of $a, b \in G$ is $[a, b] = aba^{-1}b^{-1}$. For subgroups H, K, $[H, K]$ is the subgroup generated by the $[h, k]$. The *derived subgroup* is $G' = [G, G]$, and the *derived series* is $G^{(0)} = G$, $G^{(i+1)} = [G^{(i)}, G^{(i)}]$. The group G is *solvable* if $G^{(n)} = \{e\}$ for some n.

Proposition 7.9.2. *$[G, G]$ is a normal subgroup, $G^{\mathrm{ab}} = G/[G, G]$ is abelian, and a normal subgroup N has abelian quotient G/N if and only if $[G, G] \subseteq N$. Every homomorphism from G to an abelian group factors uniquely through G^{ab}; thus $G \mapsto G^{\mathrm{ab}}$ is left adjoint to the inclusion* $\mathsf{Ab} \to \mathsf{Grp}$.

Proof. $g[a, b]g^{-1} = [gag^{-1}, gbg^{-1}]$, so $[G, G]$ is normal. The quotient G/N is abelian iff $abN = baN$ for all a, b, iff all commutators lie in N. A homomorphism f to an abelian group kills all commutators, so it factors uniquely by Theorem 7.4.3. The last statement is the resulting natural bijection $\mathrm{Hom}_{\mathsf{Grp}}(G, A) \cong \mathrm{Hom}_{\mathsf{Ab}}(G^{\mathrm{ab}}, A)$. □

Proposition 7.9.3.
1. *G is solvable if and only if there is a chain $\{e\} = G_n \trianglelefteq G_{n-1} \trianglelefteq \cdots \trianglelefteq G_0 = G$ with all G_i/G_{i+1} abelian.*
2. *Subgroups and quotients of solvable groups are solvable. If $N \trianglelefteq G$ and both N and G/N are solvable, then G is solvable.*
3. *p-groups are solvable, and S_n is not solvable for $n \geq 5$.*

Proof. (1) The derived series is such a chain. Conversely, given a chain, induction shows $G^{(i)} \subseteq G_i$, because G_i/G_{i+1} abelian gives $[G_i, G_i] \subseteq G_{i+1}$ (Proposition 7.9.2). (2) For $H \leq G$, $H^{(i)} \subseteq G^{(i)}$. For a surjection $f : G \to Q$, $f[G^{(i)}] = Q^{(i)}$. If $(G/N)^{(n)}$ is trivial then $G^{(n)} \subseteq N$, and then $G^{(n+m)} \subseteq N^{(m)}$ is trivial for large m. (3) By induction on $|G|$, using (2) and Proposition 7.6.7: $Z(G)$ is abelian and nontrivial, and $G/Z(G)$ is a smaller p-group. For $n \geq 5$, A_n is simple and not abelian, so $[A_n, A_n] = A_n$ and A_n, hence S_n, is not solvable. □

Example 7.9.4. S_4 is solvable: $\{e\} \trianglelefteq V \trianglelefteq A_4 \trianglelefteq S_4$, with V as in Counterexample 7.8.8, has quotients of orders 4, 3 and 2, which are abelian by Proposition 7.6.7. The failure of solvability of S_n for $n \geq 5$ is the group-theoretic reason why polynomial equations of degree ≥ 5 cannot in general be solved by radicals (Chapter 9).

Definition 7.9.5. The *upper central series* of G is defined by $Z_0 = \{e\}$ and $Z_{i+1}/Z_i = Z(G/Z_i)$ (using the correspondence theorem). The group is *nilpotent* if $Z_n = G$ for some n.

Proposition 7.9.6. *p-groups are nilpotent, and nilpotent groups are solvable. The group S_3 is solvable but not nilpotent.*

Proof. If G is a p-group and $Z_i \neq G$, then G/Z_i is a nontrivial p-group, so $Z_{i+1} \supsetneq Z_i$ by Proposition 7.6.7; hence $Z_n = G$ eventually. The chain $Z_0 \trianglelefteq Z_1 \trianglelefteq \cdots$ has abelian quotients, so nilpotent groups are solvable by Proposition 7.9.3. S_3 is solvable via $\{e\} \trianglelefteq A_3 \trianglelefteq S_3$, but $Z(S_3) = \{e\}$ (a non-identity permutation of $\{1, 2, 3\}$ does not commute with every transposition), so $Z_i = \{e\}$ for all i. □

Definition 7.9.7. A *composition series* of a group G is a chain $\{e\} = G_n \trianglelefteq G_{n-1} \trianglelefteq \cdots \trianglelefteq G_0 = G$ in which every factor G_i/G_{i+1} is simple; the factors are the *composition factors* and n is the *length*.

Theorem 7.9.8 (Jordan–Hölder)**.** *Every finite group has a composition series, and any two composition series of a finite group have the same length and the same composition factors up to isomorphism and permutation.*

Proof. Existence: by induction on $|G|$; if $G \neq \{e\}$, a normal subgroup $N \neq G$ of largest order has G/N simple by the correspondence theorem, and N has a composition series.

Uniqueness, by induction on $|G|$. Let (G_i) and (H_j) be composition series of lengths n and m. If $G_1 = H_1$, apply induction to G_1. Otherwise $H_1 \not\subseteq G_1$: if $H_1 \subsetneq G_1$, then G_1/H_1 would be a nontrivial proper normal subgroup of the simple group G/H_1. So G_1H_1 is a normal subgroup strictly containing G_1, and $G_1H_1 = G$ because G/G_1 is simple. Let $K = G_1 \cap H_1$. By Theorem 7.4.4(2), $G_1/K \cong G/H_1$ and $H_1/K \cong G/G_1$, both simple. Choose a composition series of K, of length l. Then $G_1 \trianglerighteq K \trianglerighteq \cdots$ is a composition series of G_1 of length $l+1$; by induction applied to G_1 it has the same length and factors as $G_1 \trianglerighteq G_2 \trianglerighteq \cdots$, so $n - 1 = l + 1$. Similarly $m - 1 = l + 1$. The factors of (G_i) are G/G_1, $G_1/K \cong G/H_1$ and those of K; the factors of (H_j) are G/H_1, $H_1/K \cong G/G_1$ and those of K. These agree up to permutation. □

7.10 Free groups and presentations

Definition 7.10.1. Let S be a set and $A = S \times \{1, -1\}$, whose elements we write s and s^{-1}; for $x = s^{\pm 1}$ write $x^{-1} = s^{\mp 1}$. A *word* is a finite sequence $x_1 \cdots x_k$ of elements of A, and it is *reduced* if no two adjacent letters are of the form xx^{-1}. Let $F(S)$ be the set of reduced words.

Theorem 7.10.2. *There is a unique group structure on $F(S)$ in which the product of reduced words u and v is obtained from the concatenation uv by repeatedly deleting adjacent pairs xx^{-1}. With the map $\iota\colon S \to F(S)$ sending s to the one-letter word, $F(S)$ is the* free group *on S: for every group G and map $f\colon S \to G$ there is a unique homomorphism $\bar{f}\colon F(S) \to G$ with $\bar{f} \circ \iota = f$. So F is left adjoint to the forgetful functor* Grp $\to$ Set.

Proof. For $x \in A$ define $L_x\colon F(S) \to F(S)$ by $L_x(w) = xw$ if w does not begin with x^{-1}, and $L_x(x^{-1}w') = w'$. Then $L_xL_{x^{-1}} = \mathrm{id}$ for all x, so each L_x is a bijection, and $L_{x^{-1}} = L_x^{-1}$. Let $\Phi \leq \mathrm{Sym}(F(S))$ be the subgroup generated by the L_x, and $\epsilon\colon \Phi \to F(S)$, $\pi \mapsto \pi(\emptyset)$, where $\emptyset$ is the empty word. By Lemma 7.2.8, every $\pi \in \Phi$ is a product $L_{y_1} \cdots L_{y_m}$; deleting adjacent factors $L_xL_{x^{-1}} = \mathrm{id}$ we may assume $y_1 \cdots y_m$ is reduced, and then $\pi(\emptyset) = y_1 \cdots y_m$. Hence π is determined by $\pi(\emptyset)$, and every reduced word $w = x_1 \cdots x_k$ equals $L_{x_1} \cdots L_{x_k}(\emptyset)$. So ϵ is a bijection, and we transport the group structure of Φ to $F(S)$. The product of u and v is then $L_{u_1} \cdots L_{u_k}(v)$, which is computed by the deletion process of the statement.

For $f\colon S \to G$ extend f to A by $f(s^{-1}) = f(s)^{-1}$ and define $\bar{f}(x_1 \cdots x_k) = f(x_1) \cdots f(x_k)$. The value of $f(x_1) \cdots f(x_k)$ on an arbitrary word does not change when an adjacent pair xx^{-1} is deleted, and the product in $F(S)$ is obtained from concatenation by such deletions; so $\bar{f}$ is a homomorphism. It is unique because $\iota(S)$ generates $F(S)$. □

Definition 7.10.3. Let S be a set and $R \subseteq F(S)$. The group with *presentation* $\langle S \mid R \rangle$ is $F(S)/N$, where N is the smallest normal subgroup containing R (the intersection of all normal subgroups containing R). Every group G has a presentation: take $S = G$ and R the kernel of $F(G) \to G$.

Proposition 7.10.4. *Let $G = \langle S \mid R \rangle$ and let $f\colon S \to H$ be a map to a group such that $\bar{f}(r) = e$ for all $r \in R$. Then there is a unique homomorphism $G \to H$ sending the class of each s to $f(s)$.*

Proof. $\ker \bar{f}$ is a normal subgroup containing R, hence containing N; apply Theorem 7.4.3. Uniqueness holds because the classes of S generate G. □

Example 7.10.5.
1. $\langle a \mid a^n \rangle \cong \mathbb{Z}/n\mathbb{Z}$: the homomorphism $F(\{a\}) \to \mathbb{Z}/n\mathbb{Z}$, $a \mapsto 1$, kills a^n and so induces a surjection $\langle a \mid a^n \rangle \to \mathbb{Z}/n\mathbb{Z}$; the source is generated by the class of a, which has order dividing n, so it has at most n elements.
2. $\langle a, b \mid aba^{-1}b^{-1} \rangle \cong \mathbb{Z}^2$: the map $a \mapsto (1,0)$, $b \mapsto (0,1)$ induces a surjection, and a homomorphism $\mathbb{Z}^2 \to \langle a, b \mid aba^{-1}b^{-1} \rangle$ inverse to it exists because the classes of a and b commute.
3. $D_n \cong \langle r, s \mid r^n, s^2, srsr \rangle$, by a similar argument.

Definition 7.10.6. Let $\alpha_1 \colon H \to G_1$ and $\alpha_2 \colon H \to G_2$ be homomorphisms. The *amalgamated free product* $G_1 *_H G_2$ is the group with generators the disjoint union of the sets G_1 and G_2 and relations xyz^{-1} whenever $xy = z$ holds in G_1 or in G_2, and $\alpha_1(h)\alpha_2(h)^{-1}$ for $h \in H$. If H is trivial, it is the *free product* $G_1 * G_2$.

Proposition 7.10.7. *With the evident homomorphisms $G_i \to G_1 *_H G_2$, the amalgamated free product is a pushout of $G_1 \leftarrow H \to G_2$ in* Grp. *In particular $G_1 * G_2$ is a coproduct, and* Grp *has all colimits.*

Proof. The relations of the first kind make the maps $G_i \to G_1 *_H G_2$ homomorphisms, and those of the second kind make the square commute. Given homomorphisms $f_i \colon G_i \to K$ with $f_1\alpha_1 = f_2\alpha_2$, the map on generators given by f_1 and f_2 kills all relations, so it induces a homomorphism by Proposition 7.10.4, which is unique since the images of G_1 and G_2 generate. Coproducts of arbitrary families are constructed in the same way, and coequalisers are quotients by normal subgroups; so Grp has all colimits by the dual of Theorem 6.8.6. □

Remark 7.10.8. If α_1 and α_2 are injective, the maps $G_i \to G_1 *_H G_2$ are injective, and every element has a normal form as an alternating product of coset representatives [Ser80, Chapter I, Theorem 1], [LS77, Chapter IV]. For example $\mathrm{SL}_2(\mathbb{Z}) \cong \mathbb{Z}/4\mathbb{Z} *_{\mathbb{Z}/2\mathbb{Z}} \mathbb{Z}/6\mathbb{Z}$ [Ser80, Chapter I, §4]. Amalgamated free products compute fundamental groups of unions of spaces via the Seifert–van Kampen theorem (Chapter 19).

7.11 Abelian groups

In this section groups are abelian and written additively. For $n \in \mathbb{Z}$ and $a \in A$ we write na for the n-th power of Lemma 7.2.9.

Definition 7.11.1. For a set S, let $\mathbb{Z}^{(S)}$ be the set of maps $S \to \mathbb{Z}$ that vanish outside a finite set, with pointwise addition, and e_s the map that is 1 at s and 0 elsewhere. An abelian group is *free* if it is isomorphic to some $\mathbb{Z}^{(S)}$, and a family (a_s) in A is a *basis* if the homomorphism $\mathbb{Z}^{(S)} \to A$, $e_s \mapsto a_s$, is an isomorphism. The *torsion subgroup* of A is $A_{\mathrm{tors}} = \{a : na = 0 \text{ for some } n \geq 1\}$, and A is *torsion-free* if $A_{\mathrm{tors}} = 0$.

Proposition 7.11.2. *For every abelian group A and map $f : S \to A$ there is a unique homomorphism $\mathbb{Z}^{(S)} \to A$ with $e_s \mapsto f(s)$, namely $\sum_s n_s e_s \mapsto \sum_s n_s f(s)$. If S is finite with n elements, $\mathbb{Z}^{(S)} \cong \mathbb{Z}^n$, and $\mathbb{Z}^n \cong \mathbb{Z}^m$ implies $n = m$.*

Proof. The formula defines a homomorphism, and it is forced. If $\mathbb{Z}^n \cong \mathbb{Z}^m$, then $\mathbb{Z}^n/2\mathbb{Z}^n \cong \mathbb{Z}^m/2\mathbb{Z}^m$, and these groups have 2^n and 2^m elements. □

Definition 7.11.3. The *rank* of a free abelian group $\mathbb{Z}^n$ is n; it is well defined by Proposition 7.11.2.

Proposition 7.11.4. *Every subgroup of $\mathbb{Z}^n$ is free of rank at most n.*

Proof. By induction on n; for $n = 0$ it is clear. Let $H \leq \mathbb{Z}^n$ and $p\colon \mathbb{Z}^n \to \mathbb{Z}$ the last coordinate. Then $H \cap \ker p$ is a subgroup of $\ker p \cong \mathbb{Z}^{n-1}$, hence free of rank $\leq n-1$ with some basis $(h_1, \dots, h_k)$. By Proposition 7.2.10, $p[H] = d\mathbb{Z}$. If $d = 0$, $H = H \cap \ker p$. Otherwise choose $h \in H$ with $p(h) = d$; every $x \in H$ is uniquely $x = (x - qh) + qh$ with $q = p(x)/d$ and $x - qh \in H \cap \ker p$, so $(h_1, \dots, h_k, h)$ is a basis of H. □

Theorem 7.11.5 (Smith normal form over $\mathbb{Z}$)**.** *Let M be an $m \times n$ matrix with integer entries. There are invertible integer matrices P and Q (with integer inverses) such that PMQ is diagonal, with diagonal entries $d_1, \dots, d_r, 0, \dots, 0$ where $d_i \geq 1$ and $d_1 \mid d_2 \mid \cdots \mid d_r$.*

Proof. Multiplying by invertible matrices on the left and right performs the elementary operations: swapping two rows or columns, multiplying a row or column by -1, and adding an integer multiple of one row (column) to another. We argue by induction on $m + n$; if $M = 0$ there is nothing to do. Among all matrices obtainable from M by elementary operations, choose one, M', whose smallest nonzero entry in absolute value, δ, is as small as possible; move it to position $(1, 1)$ and make it positive. Every entry a of the first row or column is divisible by δ: otherwise subtracting a multiple of the first column (row) would produce the remainder of a modulo δ, a smaller nonzero entry. So we can clear the first row and column. Every remaining entry a is also divisible by δ: otherwise adding its row to the first row and then subtracting a multiple of the first column would create a smaller nonzero entry. Apply induction to the remaining $(m-1) \times (n-1)$ block; the operations on it do not affect divisibility of its entries by δ, so $d_1 = \delta$ divides all later d_i. □

Theorem 7.11.6 (Structure of finitely generated abelian groups)**.** *Let A be a finitely generated abelian group. There are unique integers $r \geq 0$ and $d_1, \dots, d_k \geq 2$ with $d_1 \mid d_2 \mid \cdots \mid d_k$ such that*

$$A \cong \mathbb{Z}^r \oplus \mathbb{Z}/d_1\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/d_k\mathbb{Z}.$$

Here $A_{\mathrm{tors}} \cong \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$, and $A/A_{\mathrm{tors}} \cong \mathbb{Z}^r$.

Proof. Existence. Choose generators $a_1, \dots, a_n$, giving a surjection $\pi\colon \mathbb{Z}^n \to A$. By Proposition 7.11.4, $\ker \pi$ is free with a basis $v_1, \dots, v_m$, $m \leq n$. Let M be the $n \times m$ matrix with columns v_j. Changing the basis of $\mathbb{Z}^n$ corresponds to multiplying M by an invertible matrix on the left, and changing the basis of $\ker \pi$ to multiplying on the right. By Theorem 7.11.5 there are bases $f_1, \dots, f_n$ of $\mathbb{Z}^n$ and $w_1, \dots, w_m$ of $\ker \pi$ with $w_i = d_i f_i$ for $i \leq s$ and $w_i = 0$ for $i > s$; since the w_i are a basis, $s = m$ and all $d_i \geq 1$. Hence $A \cong \mathbb{Z}^n/\ker \pi \cong \bigoplus_{i \leq m} \mathbb{Z}/d_i\mathbb{Z} \oplus \mathbb{Z}^{n-m}$, and we discard the factors with $d_i = 1$.

Uniqueness. In such a decomposition the torsion subgroup is $T = \bigoplus \mathbb{Z}/d_i\mathbb{Z}$ and $A/T \cong \mathbb{Z}^r$, so r is determined by Proposition 7.11.2. For a prime p and $j \geq 0$, $p^j(\mathbb{Z}/d\mathbb{Z})/p^{j+1}(\mathbb{Z}/d\mathbb{Z})$ has order p if $p^{j+1} \mid d$ and order 1 otherwise. Hence $|p^jT/p^{j+1}T| = p^{t(p,j)}$, where $t(p, j)$ is the number of i with $p^{j+1} \mid d_i$. By the divisibility chain, these are the last $t(p, j)$ indices. So the numbers $t(p, j)$, which depend only on T, determine the exponent of p in every d_i, provided k is known; and $k = \max_p t(p, 0)$, since a prime dividing d_1 divides all d_i. □

Corollary 7.11.7. *If $\gcd(m, n) = 1$, then $\mathbb{Z}/mn\mathbb{Z} \cong \mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$. Every finite abelian group is a direct sum of cyclic groups of prime power order.*

Proof. The element $(1, 1)$ of $\mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$ has order $\operatorname{lcm}(m, n) = mn$, so it generates. Apply this to the prime factorisations of the d_i. □

Counterexample 7.11.8. The group $(\mathbb{Q}, +)$ is torsion-free but not free, and not finitely generated. Any two elements $a/b, c/d$ satisfy the nontrivial relation $bc \cdot (a/b) - ad \cdot (c/d) = 0$, so a basis would have one element, and $\mathbb{Q} \cong \mathbb{Z}$ is impossible since $\mathbb{Q}$ is divisible ($x = 2 \cdot (x/2)$) while $1 \in \mathbb{Z}$ is not twice anything. A finitely generated torsion-free group would be free by Theorem 7.11.6.

7.12 Exercises

Exercise 7.12.1 (Orbit-counting lemma)**.** Let a finite group G act on a finite set X. Show that the number of orbits is $\frac{1}{|G|}\sum_{g \in G} |X^g|$, where $X^g = \{x : gx = x\}$. Use it to count the colourings of the vertices of a square with two colours up to rotation. (This is often called *Burnside's lemma*, because it appears in Burnside's book on finite groups; it is due to Cauchy and Frobenius, and has been called "the lemma that is not Burnside's" [Neu79].)

Solution. Count the set $\{(g, x) : gx = x\}$ in two ways: it has $\sum_g |X^g|$ elements, and also $\sum_x |G_x| = \sum_x |G|/|Gx|$. Each orbit O contributes $\sum_{x \in O} |G|/|O| = |G|$ to the last sum. For the square, $G = \mathbb{Z}/4\mathbb{Z}$ acts on the $2^4 = 16$ colourings; the identity fixes 16, the rotations by $\pm\frac{\pi}{2}$ fix the 2 constant colourings, and the rotation by π fixes the 4 colourings with opposite vertices equal. So there are $\frac{1}{4}(16 + 2 + 2 + 4) = 6$ colourings up to rotation. □

Exercise 7.12.2. Show that every group of order at most 5 is abelian, and that S_3 is the smallest non-abelian group.

Exercise 7.12.3. Show that $[S_n, S_n] = A_n$ for $n \geq 2$ and $S_n^{\mathrm{ab}} \cong \mathbb{Z}/2\mathbb{Z}$.

Exercise 7.12.4. (Frattini argument.) Let $N \trianglelefteq G$ be finite and P a Sylow p-subgroup of N. Show that $G = N \cdot N_G(P)$.

Exercise 7.12.5. Let $p < q$ be primes with $p \nmid q - 1$. Show that every group of order pq is cyclic.

Exercise 7.12.6. Show that $F(S) \cong F(T)$ implies $|S| = |T|$ for finite sets S, T. (Hint: count homomorphisms to $\mathbb{Z}/2\mathbb{Z}$.)

Exercise 7.12.7. Show that the free group on two generators is not solvable. (Hint: construct a surjection onto S_5.)

Exercise 7.12.8. Let $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = ijk = -1$. Show that every subgroup of Q_8 is normal but Q_8 is not abelian, and that Q_8 is not a semidirect product of two proper subgroups.

Chapter 8

Rings and Modules

8.1 Introduction

This chapter develops the basic theory of rings and modules: ideals and quotients, prime and maximal ideals, factorisation in integral domains, polynomial rings, modules and exact sequences, tensor products, algebras, and the structure of finitely generated modules over a principal ideal domain. Commutative rings were introduced in Section 4.3; the deeper theory of commutative rings is in Chapter 14.

References are [Lan02], [DF04] and, for modules over commutative rings, [AM69].

Prerequisites. Chapter 3 (Set Theory), Chapter 4 (Number Systems), Chapter 6 (Categories) and Chapter 7 (Groups).

On the way to the Hodge conjecture. Needed: ideals, prime and maximal ideals, factorisation, polynomial rings, modules, vector spaces and rank, and tensor products (Sections 8.3 to 8.9). Graded algebras and modules over a principal ideal domain (Sections 8.10, 8.11) can be read when they are first used.

8.2 Rings

Definition 8.2.1. A *ring* is a set R with two operations, addition $(a, b) \mapsto a + b$ and multiplication $(a, b) \mapsto a \cdot b$ (usually written ab), and elements 0, 1 such that $(R, +, 0)$ is an abelian group (in additive notation, Notation 7.2.2), multiplication is associative with neutral element 1, and both distributive laws $a(b + c) = ab + ac$ and $(a + b)c = ac + bc$ hold. A *homomorphism* of rings is a map preserving $+$, $\cdot$ and 1. A *subring* is a subset containing 0 and 1 and closed under $+$, $-$ and $\cdot$. An element u is a *unit* if it has a two-sided inverse; the units form a group $R^\times$. A *division ring* is a ring with $1 \neq 0$ in which every nonzero element is a unit; a commutative division ring is a field. The rings form a category Ring, and the commutative rings a full subcategory CRing.

Remark 8.2.2. The computations of Lemma 4.3.2 hold in every ring. If $1 = 0$ then $a = 1 \cdot a = 0 \cdot a = 0$ for all a, so $R = \{0\}$ is the *zero ring*; it is the terminal object of Ring, and $\mathbb{Z}$ is the initial object (Exercise 4.11.5).

Example 8.2.3.

1. $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{Z}/n\mathbb{Z}$ with the multiplication $[a][b] = [ab]$, which is well defined since $a - a' \in n\mathbb{Z}$ implies $ab - a'b \in n\mathbb{Z}$.
2. For a ring R, the $n \times n$ matrices $M_n(R)$ form a ring under matrix addition and multiplication; it is not commutative for $n \geq 2$ if $1 \neq 0$.
3. For an abelian group A, the endomorphisms $\mathrm{End}(A)$ form a ring under pointwise addition and composition.

4. The product $\prod_i R_i$ of rings with componentwise operations is a product in Ring.

5. The *quaternions* $\mathbb{H}$ are the matrices $\begin{pmatrix} z & -\bar{w} \\ w & \bar{z} \end{pmatrix}$ with $z, w \in \mathbb{C}$. They form a subring of $M_2(\mathbb{C})$, and a division ring: the determinant of such a matrix is $|z|^2 + |w|^2$, and if it is nonzero the inverse $\frac{1}{|z|^2+|w|^2}\begin{pmatrix} \bar{z} & \bar{w} \\ -w & z \end{pmatrix}$ is again of this form. With $i = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}$, $j = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ and $k = ij$ we get $i^2 = j^2 = k^2 = ijk = -1$, so $\mathbb{H}$ is not commutative.

8.3 Ideals and quotient rings

Definition 8.3.1. A *left ideal* of a ring R is an additive subgroup I with $ra \in I$ for $r \in R$, $a \in I$; right ideals are defined similarly, and a (two-sided) *ideal* is both. For a commutative ring these notions agree. The ideal generated by a subset S of a commutative ring is $(S) = \{r_1 s_1 + \cdots + r_n s_n : r_i \in R, s_i \in S\}$; an ideal of the form (a) is *principal*. For ideals I, J of a commutative ring, $I + J$, $I \cap J$ and the product IJ, generated by the products ab with $a \in I$, $b \in J$, are ideals, and $IJ \subseteq I \cap J$.

Theorem 8.3.2. *Let I be an ideal of R. The quotient group R/I is a ring with $(a + I)(b + I) = ab + I$, and $\pi\colon R \to R/I$ is a surjective ring homomorphism with kernel I. Every ring homomorphism $f\colon R \to S$ with $I \subseteq \ker f$ factors uniquely as $\bar{f} \circ \pi$. Kernels of ring homomorphisms are ideals, and $R/\ker f \cong \operatorname{im} f$. The ideals of R/I correspond to the ideals of R containing I via $J \mapsto J/I$, and $(R/I)/(J/I) \cong R/J$.*

Proof. If $a - a', b - b' \in I$, then $ab - a'b' = a(b - b') + (a - a')b' \in I$, so the product is well defined; the ring axioms follow from those of R. The remaining statements follow from Theorems 7.4.3 and 7.4.4 applied to the additive groups, together with the observation that the maps constructed there preserve products and that preimages and images of ideals under surjective ring homomorphisms are ideals. □

Theorem 8.3.3 (Chinese remainder theorem)**.** *Let R be a commutative ring and $I_1, \ldots, I_n$ ideals with $I_i + I_j = R$ for $i \neq j$. Then $I_1 \cap \cdots \cap I_n = I_1 \cdots I_n$, and the map $R \to \prod_i R/I_i$ induces an isomorphism $R/(I_1 \cap \cdots \cap I_n) \cong \prod_i R/I_i$.*

Proof. For $n = 2$: write $1 = a + b$ with $a \in I_1$, $b \in I_2$. If $x \in I_1 \cap I_2$ then $x = xa + xb \in I_1 I_2$. Given $r_1, r_2 \in R$, the element $r_1 b + r_2 a$ is congruent to r_1 modulo I_1 and to r_2 modulo I_2, so the map is surjective; its kernel is $I_1 \cap I_2$. For $n > 2$, note that $I_1 + I_2 \cdots I_n = R$: from $1 = a_j + b_j$ with $a_j \in I_1$, $b_j \in I_j$ we get $1 = \prod_{j \geq 2}(a_j + b_j) \in I_1 + I_2 \cdots I_n$. Now use induction. □

Example 8.3.4. If $n = p_1^{e_1} \cdots p_k^{e_k}$ with distinct primes p_i, then $\mathbb{Z}/n\mathbb{Z} \cong \prod_i \mathbb{Z}/p_i^{e_i}\mathbb{Z}$ as rings, since $(p_i^{e_i}) + (p_j^{e_j}) = \mathbb{Z}$ by Theorem 4.5.3.

8.4 Prime and maximal ideals

In this section all rings are commutative.

Definition 8.4.1. An ideal $\mathfrak{p} \neq R$ is *prime* if $ab \in \mathfrak{p}$ implies $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$. An ideal $\mathfrak{m} \neq R$ is *maximal* if there is no ideal J with $\mathfrak{m} \subsetneq J \subsetneq R$.

Proposition 8.4.2. *An ideal I is prime if and only if R/I is an integral domain, and maximal if and only if R/I is a field. In particular maximal ideals are prime.*

Proof. The first statement is a restatement of the definitions. A commutative ring $K \neq 0$ is a field if and only if its only ideals are 0 and K: if $a \neq 0$ then $(a) = K$ means a is a unit. By the correspondence of ideals in Theorem 8.3.2, R/I has only the ideals 0 and R/I exactly when I is maximal. □

Theorem 8.4.3 (Krull)**.** *Every ideal $I \neq R$ is contained in a maximal ideal. In particular every nonzero ring has a maximal ideal.*

Proof. Let P be the set of ideals J with $I \subseteq J \neq R$, ordered by inclusion. It contains I. The union of a nonempty chain in P is an ideal, and it does not contain 1, so it lies in P. By Zorn's lemma (Theorem 3.7.2) P has a maximal element, which is a maximal ideal. □

Example 8.4.4. The ideals of $\mathbb{Z}$ are the $n\mathbb{Z}$ (Proposition 7.2.10). The prime ideals are 0 and $p\mathbb{Z}$ for p prime, by Lemma 4.5.4, and the maximal ideals are the $p\mathbb{Z}$. Hence $\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime; we write $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$. The prime ideal 0 is not maximal.

Definition 8.4.5. The *characteristic* of a ring R is the $n \geq 0$ with $\ker(\mathbb{Z} \to R) = n\mathbb{Z}$.

Lemma 8.4.6. *The characteristic of an integral domain is* 0 *or a prime number.*

Proof. The image of $\mathbb{Z} \to R$ is a subring of a domain, hence a domain, so the kernel is a prime ideal of $\mathbb{Z}$. □

Proposition 8.4.7. *Let R be an integral domain. There is a field* $\mathrm{Frac}(R)$ *and an injective homomorphism $R \to \mathrm{Frac}(R)$ such that every injective homomorphism from R to a field K extends uniquely to a homomorphism* $\mathrm{Frac}(R) \to K$.

Proof. Construct $\mathrm{Frac}(R)$ as the set of classes a/b of pairs with $b \neq 0$ under $(a, b) \sim (c, d) \iff ad = bc$, with the operations of Definition 4.6.1; the verification of Theorem 4.6.2 only used that $\mathbb{Z}$ is an integral domain. Given $f : R \to K$ injective, $f(b) \neq 0$ for $b \neq 0$, and $a/b \mapsto f(a)f(b)^{-1}$ is the unique extension, as in Proposition 4.6.3. □

8.5 Factorisation in integral domains

In this section R is an integral domain.

Definition 8.5.1. Elements a, b are *associates* if $a = ub$ with $u \in R^\times$. A nonzero nonunit a is *irreducible* if $a = bc$ implies that b or c is a unit, and *prime* if $a \mid bc$ implies $a \mid b$ or $a \mid c$. The domain R is a *unique factorisation domain* (UFD) if every nonzero nonunit is a product of irreducible elements, and this product is unique up to order and associates. It is a *principal ideal domain* (PID) if every ideal is principal, and a *Euclidean domain* if there is a map $N : R \setminus \{0\} \to \mathbb{N}$ such that for all a and $b \neq 0$ there are q, r with $a = qb + r$ and $r = 0$ or $N(r) < N(b)$.

Lemma 8.5.2. *A nonzero element p is prime if and only if (p) is a prime ideal. Prime elements are irreducible.*

Proof. The first statement is a restatement. If p is prime and $p = bc$, then $p \mid b$ or $p \mid c$, say $b = pd$; then $p = pdc$, so $dc = 1$ and c is a unit. □

Lemma 8.5.3. *Suppose every nonzero nonunit of R is a product of irreducible elements. Then R is a UFD if and only if every irreducible element is prime.*

Proof. If irreducibles are prime, uniqueness follows as in the proof of Theorem 4.5.5: a prime dividing a product of irreducibles divides one of them, hence is associate to it, and we cancel. Conversely, let R be a UFD, p irreducible and $p \mid bc$, say $bc = pd$. Factoring b, c and d into irreducibles and comparing the two factorisations of bc shows that p is associate to an irreducible factor of b or of c (if b or c is a unit or zero the claim is immediate). □

Theorem 8.5.4. *A Euclidean domain is a PID, and a PID is a UFD.*

Proof. Let R be Euclidean and $I \neq 0$ an ideal; choose $b \in I \setminus \{0\}$ with $N(b)$ minimal. For $a \in I$ write $a = qb + r$; then $r \in I$, so $r = 0$ and $I = (b)$.

Let R be a PID. The union of a chain of ideals $(a_1) \subseteq (a_2) \subseteq \cdots$ is an ideal (a), and $a \in (a_n)$ for some n, so the chain is eventually constant. If some nonzero nonunit a were not a product of irreducibles, then a is not irreducible, so $a = bc$ with b, c nonunits, one of which, say a_1, is not a product of irreducibles; and $(a) \subsetneq (a_1)$. Repeating gives a strictly increasing chain of principal ideals, a contradiction. (The repeated choices are made using the axiom of choice in the form of Theorem 3.4.6 applied to a choice function.) Finally, if p is irreducible then (p) is maximal: if $(p) \subseteq (c) \neq R$ then $p = cd$ with c a nonunit, so d is a unit and $(c) = (p)$. Hence (p) is prime by Proposition 8.4.2, and R is a UFD by Lemma 8.5.3. □

Example 8.5.5. The ring $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\} \subseteq \mathbb{C}$ of *Gaussian integers* is Euclidean for $N(z) = |z|^2$. Let $a, b \in \mathbb{Z}[i]$, $b \neq 0$, and write $a/b = u + vi$ with $u, v \in \mathbb{Q}$. Choose integers m, n with $|u - m| \leq 1/2$ and $|v - n| \leq 1/2$, and put $q = m + ni$, $r = a - qb \in \mathbb{Z}[i]$. Then $N(r) = |b|^2|a/b - q|^2 \leq N(b)(1/4 + 1/4) < N(b)$.

Counterexample 8.5.6. The ring $R = \mathbb{Z}[\sqrt{-5}] = \{a + b\sqrt{-5} : a, b \in \mathbb{Z}\} \subseteq \mathbb{C}$ is not a UFD. The norm $N(z) = |z|^2 = a^2 + 5b^2$ is multiplicative and takes values in $\mathbb{N}$, and the units are the elements of norm 1, namely ± 1. No element has norm 2 or 3. Hence 2 (norm 4) is irreducible: a factorisation into nonunits would have factors of norm 2. But 2 divides $6 = (1 + \sqrt{-5})(1 - \sqrt{-5})$ without dividing either factor, since $N(1 \pm \sqrt{-5}) = 6$ is not divisible by $N(2) = 4$. So 2 is irreducible but not prime.

8.6 Polynomial rings

Definition 8.6.1. Let R be a ring. The *polynomial ring* $R[x]$ is the set of sequences $(a_0, a_1, \ldots)$ in R with only finitely many nonzero terms, with termwise addition and the product $(a_i)(b_j) = (c_k)$, $c_k = \sum_{i+j=k} a_i b_j$. We identify $r \in R$ with $(r, 0, 0, \ldots)$ and write $x = (0, 1, 0, \ldots)$, so that every polynomial is uniquely $f = \sum_{i=0}^{n} a_i x^i$ (Lemma 8.6.2). If $f \neq 0$, its *degree* $\deg f$ is the largest i with $a_i \neq 0$, and $a_{\deg f}$ is the *leading coefficient*; f is *monic* if the leading coefficient is 1. The ring $R[x_1, \ldots, x_n]$ is defined inductively as $R[x_1, \ldots, x_{n-1}][x_n]$, and the *power series ring* $R[[x]]$ is defined like $R[x]$ but with all sequences allowed.

Informally a polynomial is an expression $a_0 + a_1 x + \cdots + a_n x^n$ in a symbol x about which nothing is assumed except the ring axioms. The definition makes this precise by keeping only what matters, the list of coefficients; the symbol x then becomes an honest element of the ring. A polynomial is not a function: over $\mathbb{F}_2 = \mathbb{Z}/2\mathbb{Z}$, the polynomial $x^2 + x$ is not zero, as its coefficient sequence is $(0, 1, 1, 0, \ldots)$, but the function $a \mapsto a^2 + a$ vanishes at both elements of $\mathbb{F}_2$. The next lemma checks that the definition does what the notation promises.

Lemma 8.6.2. *Let R be a ring, and for $n \geq 0$ let $e_n \in R[x]$ be the sequence with 1 in position n and 0 elsewhere.*

1. *$R[x]$ is a ring with zero $(0, 0, \ldots)$ and unit $e_0 = (1, 0, 0, \ldots)$; it is commutative if R is. The map $R \to R[x]$, $r \mapsto (r, 0, 0, \ldots)$, is an injective ring homomorphism.*

2. *$x^n = e_n$ for all $n \geq 0$, and rx^n is the sequence with r in position n and 0 elsewhere.*

3. *The polynomial $(a_0, a_1, \ldots, a_n, 0, 0, \ldots)$ equals $\sum_{i=0}^{n} a_i x^i$. Consequently every polynomial is a finite sum $\sum_i a_i x^i$, and $\sum_{i=0}^{n} a_i x^i = \sum_{i=0}^{n} b_i x^i$ only if $a_i = b_i$ for all i.*

Proof. (1) The product of two finitely supported sequences is finitely supported: if $a_i = 0$ for $i > n$ and $b_j = 0$ for $j > m$, then $c_k = 0$ for $k > n + m$. Addition is termwise, so $(R[x], +)$ is an abelian group. Associativity: the coefficient of index l in both $(fg)h$ and $f(gh)$ is $\sum_{i+j+k=l} a_i b_j c_k$, the sum over all triples of indices with sum l. Distributivity holds because c_k is additive in each factor. For the unit, $(e_0)_i = 0$ for $i > 0$, so the coefficient of index k in $e_0 f$ is $1 \cdot a_k = a_k$, and similarly for $f e_0$. If R is commutative, so is the formula for c_k, as $\sum_{i+j=k} a_i b_j = \sum_{i+j=k} b_i a_j$. Finally $r \mapsto (r, 0, \ldots)$ is additive, injective, sends 1 to e_0, and $(r, 0, \ldots)(s, 0, \ldots) = (rs, 0, \ldots)$, since the only nonzero term of the product formula is $c_0 = rs$.

(2) By induction on n: $x^0 = e_0$ is the unit, and if $x^n = e_n$, then $x^{n+1} = e_n \cdot e_1$ has coefficient $c_k = \sum_{i+j=k} (e_n)_i (e_1)_j$, whose only possibly nonzero term has $i = n$ and $j = 1$; so $c_k = 1$ for $k = n + 1$ and $c_k = 0$ otherwise, that is, $x^{n+1} = e_{n+1}$. For the second statement, in $(r, 0, \ldots) \cdot e_n$ only the term with $i = 0$, $j = n$ survives, giving r in position n.

(3) By (2), $\sum_{i=0}^{n} a_i x^i$ is a sum of sequences with a_i in position i and zeros elsewhere, which is $(a_0, \ldots, a_n, 0, \ldots)$ because addition is termwise. Every polynomial has finitely many nonzero terms, so it is of this form for some n. Two such sums are equal exactly when the sequences (a_i) and (b_i) are equal. □

Proposition 8.6.3. *Let $\varphi \colon R \to S$ be a ring homomorphism and $s \in S$ an element commuting with all elements of $\varphi(R)$. There is a unique ring homomorphism $R[x] \to S$ extending φ and sending x to s, namely $\sum a_i x^i \mapsto \sum \varphi(a_i) s^i$. In particular, for R commutative, $R[x_1, \ldots, x_n]$ is the free commutative R-algebra on $x_1, \ldots, x_n$: homomorphisms to a commutative ring S extending φ correspond to n-tuples of elements of S.*

Proof. The formula is forced, and it preserves products because s commutes with the $\varphi(a_i)$: $\big(\sum \varphi(a_i) s^i\big)\big(\sum \varphi(b_j) s^j\big) = \sum_k \big(\sum_{i+j=k} \varphi(a_i)\varphi(b_j)\big) s^k$. The last statement follows by induction on n. □

Notation 8.6.4. For R commutative, $f \in R[x]$ and $a \in R$, we write $f(a)$ for the image of f under the homomorphism $R[x] \to R$ with $x \mapsto a$. An element a with $f(a) = 0$ is a *root* of f.

Proposition 8.6.5. *If R is an integral domain, then* $\deg(fg) = \deg f + \deg g$ *for nonzero f, g, so $R[x]$ is an integral domain and $R[x]^\times = R^\times$.*

Proof. The coefficient of $x^{\deg f + \deg g}$ in fg is the product of the leading coefficients, which is nonzero; all higher coefficients vanish. If $fg = 1$ then $\deg f = \deg g = 0$. □

Theorem 8.6.6 (Division with remainder)**.** *Let R be commutative and $g \in R[x]$ a polynomial whose leading coefficient is a unit. For every $f \in R[x]$ there are unique $q, r \in R[x]$ with $f = qg + r$ and $r = 0$ or $\deg r < \deg g$. Consequently, if k is a field then $k[x]$ is Euclidean with $N = \deg$, hence a PID and a UFD.*

Proof. Existence by induction on $\deg f$: if $f = 0$ or $\deg f < \deg g$ take $q = 0$. Otherwise, with a and b the leading coefficients of f and g, the polynomial $f - ab^{-1} x^{\deg f - \deg g} g$ has smaller degree or is zero. Uniqueness: if $qg + r = q'g + r'$ with $q \neq q'$, then $(q - q')g = r' - r$ has degree $\geq \deg g$, because the leading coefficient of g is a unit (so it is not a zero divisor), which is impossible. The last statement follows from Theorem 8.5.4. □

Corollary 8.6.7. *Let R be commutative, $f \in R[x]$ and $a \in R$. Then $f(a) = 0$ if and only if $(x - a) \mid f$. If R is an integral domain and $f \neq 0$, then f has at most* $\deg f$ *roots in R.*

Proof. Divide: $f = q(x-a) + r$ with $r \in R$, and $r = f(a)$. If R is a domain and $a_1, \dots, a_m$ are distinct roots, induction shows $(x-a_1)\cdots(x-a_m) \mid f$: if $f = (x-a_1)g$ then $0 = f(a_j) = (a_j - a_1)g(a_j)$ gives $g(a_j) = 0$ for $j \geq 2$. So $m \leq \deg f$ by Proposition 8.6.5. □

Counterexample 8.6.8. The hypothesis that R is a domain is needed: in $\mathbb{Z}/8\mathbb{Z}$ the polynomial $x^2 - 1$ of degree 2 has the four roots $1, 3, 5, 7$.

Adjoining elements. The phrase "adjoin an element" is used in three related senses, which the polynomial ring connects.

1. *Inside a given ring.* If $R \subseteq S$ are commutative rings and $s \in S$, then $R[s]$ denotes the smallest subring of S containing R and s, the intersection of all such subrings; likewise $R[s_1, \dots, s_n]$. For example $\mathbb{Z}[i] \subseteq \mathbb{C}$, $\mathbb{Z}[\sqrt{2}] \subseteq \mathbb{R}$, and $\mathbb{Q}[\pi] \subseteq \mathbb{R}$.

2. *Freely.* $R[x]$ is R with a new element x adjoined that satisfies no relation beyond the ring axioms: by Lemma 8.6.2(3), $\sum a_i x^i = 0$ only if all $a_i = 0$.

3. *With a prescribed relation.* To adjoin to R an element satisfying an equation $f = 0$, with $f \in R[x]$, even when no larger ring containing such an element is given, one takes the quotient $R[x]/(f)$ (Theorem 8.3.2), in which the class of x satisfies f. For instance $\mathbb{R}[x]/(x^2+1)$ is $\mathbb{R}$ with a square root of -1 adjoined, a copy of $\mathbb{C}$, and for an irreducible f over a field K the quotient $K[x]/(f)$ is a field containing a root of f (Chapter 9, Kronecker's construction).

For fields one also adjoins inverses: $K(s)$ is the smallest subfield containing K and s (Chapter 9). The next proposition shows that the first sense reduces to the other two.

Proposition 8.6.9. *Let $R \subseteq S$ be commutative rings, $s \in S$, and $\mathrm{ev}_s \colon R[x] \to S$ the homomorphism $f \mapsto f(s)$ of Proposition 8.6.3.*

1. *$R[s] = \{f(s) : f \in R[x]\} = \{a_0 + a_1 s + \cdots + a_n s^n : n \geq 0, a_i \in R\}$, and ev_s induces an isomorphism $R[x]/\ker(\mathrm{ev}_s) \cong R[s]$.*

2. *If no nonzero polynomial vanishes at s, then $R[s] \cong R[x]$, by $f \mapsto f(s)$.*

3. *If $\ker(\mathrm{ev}_s)$ contains a monic polynomial m of degree d, then every element of $R[s]$ can be written as $a_0 + a_1 s + \cdots + a_{d-1}s^{d-1}$ with $a_i \in R$. If moreover $\ker(\mathrm{ev}_s) = (m)$, this expression is unique, and $R[s] \cong R[x]/(m)$.*

Here, as in Notation 8.6.4, $f(s)$ denotes $\mathrm{ev}_s(f) = \sum a_i s^i$ for $f = \sum a_i x^i$.

Proof. (1) The image of a ring homomorphism is a subring; this one contains R (constant polynomials) and $s = \mathrm{ev}_s(x)$. Conversely, a subring containing R and s contains all powers s^i, all products $a_i s^i$ and all finite sums of these, which are the elements $f(s)$. So the image is the smallest such subring. The isomorphism is the first isomorphism theorem (Theorem 8.3.2). (2) The kernel is zero. (3) Dividing f by the monic m (Theorem 8.6.6) gives $f = qm + r$ with $r = 0$ or $\deg r < d$, so $f(s) = r(s)$ has the stated form. If $\ker(\mathrm{ev}_s) = (m)$ and $r_1(s) = r_2(s)$ with $\deg r_1, \deg r_2 < d$, then $r_1 - r_2 \in (m)$ has degree less than $d = \deg m$, hence is 0, since a nonzero multiple hm of the monic m has degree $\deg h + d \geq d$ (its leading coefficient is that of h). The isomorphism is the one of (1). □

Example 8.6.10. 1. $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$ (Example 8.5.5). The kernel of $\mathrm{ev}_i \colon \mathbb{Z}[x] \to \mathbb{C}$ is (x^2+1): it contains x^2+1, and if $f(i) = 0$, divide $f = q(x^2+1) + a + bx$; then $a + bi = 0$ forces $a = b = 0$. So $\mathbb{Z}[i] \cong \mathbb{Z}[x]/(x^2+1)$, and each element is uniquely $a + bi$.

2. Similarly $\mathbb{Z}[\sqrt{2}] = \{a + b\sqrt{2} : a, b \in \mathbb{Z}\} \cong \mathbb{Z}[x]/(x^2 - 2)$: if $f(\sqrt{2}) = 0$, divide $f = q(x^2 - 2) + a + bx$; then $a + b\sqrt{2} = 0$ forces $b = 0$, as $\sqrt{2}$ is irrational, and then $a = 0$.

3. $\mathbb{Z}[\frac{1}{2}] = \{a/2^n : a \in \mathbb{Z}, n \geq 0\} \subseteq \mathbb{Q}$, since $\sum_i a_i 2^{-i} = (\sum_i a_i 2^{n-i})/2^n$ for n at least the degree. Here the kernel of $\mathrm{ev}_{1/2}\colon \mathbb{Z}[x] \to \mathbb{Q}$ contains $2x - 1$, which is not monic, and (3) does not apply: no bound on the powers of $\frac{1}{2}$ suffices, since $\frac{1}{2^n}$ is not an integer combination of $1, \frac{1}{2}, \ldots, \frac{1}{2^{n-1}}$ (multiply by 2^{n-1}).

4. No nonzero polynomial with rational coefficients vanishes at π (Lindemann, 1882; a proof is in [Lan02, Appendix 1]), so $\mathbb{Q}[\pi] \cong \mathbb{Q}[x]$ by (2): the real numbers $f(\pi)$, $f \in \mathbb{Q}[x]$, multiply and add exactly like the polynomials f.

Proposition 8.6.11. *Let R be commutative. A power series $f = \sum a_i x^i \in R[[x]]$ is a unit if and only if a_0 is a unit of R.*

Proof. If $fg = 1$ then $a_0 b_0 = 1$. Conversely, if a_0 is a unit define $b_0 = a_0^{-1}$ and recursively $b_k = -a_0^{-1} \sum_{i=1}^{k} a_i b_{k-i}$; then $\sum_{i+j=k} a_i b_j = 0$ for $k \geq 1$. □

Definition 8.6.12. Let R be a UFD. A *greatest common divisor* of elements of R is a common divisor divisible by every common divisor; it exists (take the product of the common prime factors with their minimal multiplicities) and is unique up to associates. The *content* $c(f)$ of a nonzero $f \in R[x]$ is a greatest common divisor of its coefficients, and f is *primitive* if $c(f)$ is a unit.

Lemma 8.6.13 (Gauss)**.** *Let R be a UFD. A product of primitive polynomials is primitive, and $c(fg) = c(f)c(g)$ up to associates.*

Proof. If f, g are primitive and a prime p divides all coefficients of fg, then the images of f and g in $(R/(p))[x]$ are nonzero but their product is zero; this is impossible because $R/(p)$ is a domain, hence so is $(R/(p))[x]$ (Proposition 8.6.5). In general write $f = c(f) f_0$ and $g = c(g) g_0$ with f_0, g_0 primitive; then $fg = c(f)c(g) f_0 g_0$ with $f_0 g_0$ primitive. □

Theorem 8.6.14. *Let R be a UFD with fraction field K.*

1. *A primitive polynomial $f \in R[x]$ of positive degree is irreducible in $R[x]$ if and only if it is irreducible in $K[x]$.*

2. *$R[x]$ is a UFD, whose prime elements are the prime elements of R and the primitive polynomials of positive degree that are irreducible in $K[x]$.*

Consequently $\mathbb{Z}[x_1, \ldots, x_n]$ and $k[x_1, \ldots, x_n]$ for a field k are UFDs.

Proof. Every $h \in K[x]$, $h \neq 0$, can be written $h = a h_0$ with $a \in K^\times$ and $h_0 \in R[x]$ primitive (clear denominators, then divide by the content), and if also $h = a' h_0'$ then $h_0' = u h_0$ with $u \in R^\times$: writing $a/a' = b/b'$ with $b, b' \in R$, $b h_0 = b' h_0'$ and comparing contents gives $b = b'u$.

(1) If $f = gh$ in $K[x]$ with $\deg g, \deg h > 0$, write $g = a g_0$, $h = b h_0$; then $f = ab\, g_0 h_0$ with $g_0 h_0$ primitive (Lemma 8.6.13), so $ab \in R^\times$ by the uniqueness just shown, and $f = (ab\, g_0) h_0$ is a factorisation in $R[x]$ into polynomials of positive degree. Conversely a factorisation in $R[x]$ of a primitive polynomial into nonunits has both factors of positive degree (a constant factor would divide the content), hence is a factorisation in $K[x]$.

(2) A prime p of R is prime in $R[x]$ since $R[x]/(p) \cong (R/(p))[x]$ is a domain. Let f be primitive of positive degree and irreducible in $K[x]$, and suppose $f \mid gh$ in $R[x]$ with $g, h \neq 0$. Since $K[x]$ is a PID, f is prime in $K[x]$, so say $g = fq$ with $q \in K[x]$. Write $q = a q_0$ with $a = c/c'$, $c, c' \in R$ and $q_0 \in R[x]$ primitive. Then $c' g = c\, f q_0$, and comparing contents using

Lemma 8.6.13 gives $c = c'c(g)u$ with $u \in R^\times$, so $a \in R$ and $q \in R[x]$. Hence f is prime in $R[x]$.

Every irreducible element of $R[x]$ is of one of these two kinds: an irreducible of degree 0 is irreducible in R, hence prime in R; an irreducible f of positive degree is primitive (otherwise $c(f)$ would be a nonunit factor), hence irreducible in $K[x]$ by (1). Every nonzero nonunit of $R[x]$ is a product of irreducibles: write $f = c(f)f_0$, factor $c(f)$ in R, and factor f_0 in $K[x]$ into irreducibles, which by the first paragraph and (1) can be taken primitive in $R[x]$, the remaining constant being a unit of R by Lemma 8.6.13. By Lemma 8.5.3, $R[x]$ is a UFD. The last statement follows by induction from $\mathbb{Z}$ and k being UFDs. □

Proposition 8.6.15 (Eisenstein's criterion)**.** *Let R be a UFD with fraction field K, $f = a_n x^n + \cdots + a_0 \in R[x]$ with $n \geq 1$, and p a prime of R with $p \nmid a_n$, $p \mid a_i$ for $i < n$ and $p^2 \nmid a_0$. Then f is irreducible in $K[x]$.*

Proof. By Theorem 8.6.14(1) applied to $f/c(f)$ (note $p \nmid c(f)$) it suffices to exclude $f = gh$ in $R[x]$ with $\deg g, \deg h \geq 1$. Reducing modulo p gives $\bar{g}\bar{h} = \bar{a}_n x^n$ in $(R/(p))[x]$, which embeds in $L[x]$ for $L = \mathrm{Frac}(R/(p))$. By unique factorisation in $L[x]$, $\bar{g} = bx^k$ and $\bar{h} = cx^{n-k}$ with $k = \deg g$ and $n - k = \deg h$ both positive. So p divides the constant terms of g and h, and $p^2 \mid a_0$, a contradiction. □

Counterexample 8.6.16. A UFD need not be a PID: in $\mathbb{Z}[x]$ the ideal $(2, x)$ is not principal. If $(2, x) = (f)$, then $f \mid 2$, so $f = \pm 1$ or $f = \pm 2$. But $2 \nmid x$, and $1 \notin (2, x)$ since every element of $(2, x)$ has even constant term.

8.7 Modules

Definition 8.7.1. Let R be a ring. A (left) *R-module* is an abelian group M with a map $R \times M \to M, (r, m) \mapsto rm$, such that $r(m+m') = rm+rm'$, $(r+s)m = rm+sm$, $(rs)m = r(sm)$ and $1m = m$; equivalently, a ring homomorphism $R \to \mathrm{End}(M)$. A *homomorphism* (or R-linear map) is an additive map with $f(rm) = rf(m)$. *Submodules* are subgroups closed under the action. The set $\mathrm{Hom}_R(M, N)$ of homomorphisms is an abelian group, and an R-module if R is commutative. The small R-modules form a category R-Mod.

Example 8.7.2.

1. R is a module over itself, and its submodules are its left ideals.
2. A $\mathbb{Z}$-module is the same thing as an abelian group, by Lemma 7.2.9.
3. A module over a field k is a *vector space*.
4. A $k[x]$-module is a k-vector space V together with a k-linear map $T : V \to V$ (the action of x), by Proposition 8.6.3.

Proposition 8.7.3. *Quotients M/N by submodules are modules, and the isomorphism and correspondence theorems of Theorem 7.4.4 hold for modules. For a family $(M_i)_{i \in I}$, the product $\prod_i M_i$ and the* direct sum $\bigoplus_i M_i = \{(m_i) \in \prod_i M_i : m_i = 0 \text{ for almost all } i\}$ *are a product and a coproduct in R-Mod. The category R-Mod is additive (Definition 6.12.1), has kernels and cokernels, and has all limits and colimits.*

Proof. The action on M/N is $r(m + N) = rm + N$, well defined since N is a submodule; the maps in the isomorphism theorems are R-linear. The universal properties of $\prod$ and $\bigoplus$ are verified componentwise; for $\bigoplus$, a family $f_i : M_i \to N$ gives $(m_i) \mapsto \sum_i f_i(m_i)$, a finite sum. Hom sets are abelian groups with bilinear composition, 0 is a zero object, and finite products exist, so the category is additive. The kernel of f is $\ker f \to M$ and the cokernel is

$N \to N/\operatorname{im} f$. Equalisers of f, g are kernels of $f - g$, so all limits exist by Theorem 6.8.6, and dually all colimits exist. □

Definition 8.7.4. For a set S, the *free module* $R^{(S)} = \bigoplus_{s \in S} R$ has basis vectors e_s. A family $(m_s)_{s \in S}$ in M *generates* M if every element is a finite R-linear combination of the m_s, is *linearly independent* if $\sum r_s m_s = 0$ implies all $r_s = 0$, and is a *basis* if both hold. M is *finitely generated* if it has a finite generating family.

Proposition 8.7.5. *For every module M and family $(m_s)_{s \in S}$ in M there is a unique homomorphism $R^{(S)} \to M$ with $e_s \mapsto m_s$. It is surjective iff the family generates, injective iff it is linearly independent. Every module is a quotient of a free module, and a finitely generated module is a quotient of some R^n.*

Proof. The map is $(r_s) \mapsto \sum r_s m_s$. The other statements are immediate; take the family of all elements of M (or a finite generating family). □

Definition 8.7.6. A sequence of homomorphisms $\cdots \to M_{i-1} \xrightarrow{f_{i-1}} M_i \xrightarrow{f_i} M_{i+1} \to \cdots$ is *exact* at M_i if $\operatorname{im} f_{i-1} = \ker f_i$, and exact if it is exact everywhere. A *short exact sequence* is an exact sequence $0 \to A \xrightarrow{f} B \xrightarrow{g} C \to 0$.

Proposition 8.7.7 (Splitting lemma)**.** *For a short exact sequence $0 \to A \xrightarrow{f} B \xrightarrow{g} C \to 0$ the following are equivalent:*

1. *there is $r \colon B \to A$ with $rf = \mathrm{id}_A$;*
2. *there is $s \colon C \to B$ with $gs = \mathrm{id}_C$;*
3. *there is an isomorphism $h \colon B \to A \oplus C$ with $h f(a) = (a, 0)$ and $g = \mathrm{pr}_C \circ h$.*

The sequence is then called split*. If C is free, the sequence splits.*

Proof. (1) $\Rightarrow$ (3): $h = (r, g)$ is injective (if $r(b) = 0$ and $g(b) = 0$ then $b = f(a)$ and $a = rf(a) = 0$) and surjective (given (a, c), pick b with $g(b) = c$; then $b - fr(b) + f(a)$ maps to (a, c)). (2) $\Rightarrow$ (3): the map $A \oplus C \to B$, $(a, c) \mapsto f(a) + s(c)$, is bijective by a similar check; take its inverse. (3) $\Rightarrow$ (1), (2): take $r = \mathrm{pr}_A \circ h$ and $s = h^{-1} \circ \iota_C$. If C has a basis (c_s), choose preimages b_s and define $s(c_s) = b_s$ using Proposition 8.7.5. □

Counterexample 8.7.8. The sequence $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ of abelian groups is exact but not split, since $\mathbb{Z}$ has no element of order 2 and so cannot contain a copy of $\mathbb{Z}/2\mathbb{Z}$.

8.8 Vector spaces and rank

Lemma 8.8.1 (Exchange lemma)**.** *Let k be a field and V a vector space generated by $v_1, \dots, v_n$. Then any $n + 1$ vectors $w_1, \dots, w_{n+1}$ in V are linearly dependent.*

Proof. Induction on n. For $n = 0$, $V = 0$ and $w_1 = 0$. For $n \geq 1$ write $w_j = \sum_{i=1}^{n} a_{ij} v_i$. If $a_{nj} = 0$ for all j, then $w_1, \dots, w_n$ lie in the span of $v_1, \dots, v_{n-1}$ and are dependent by induction. Otherwise, renumbering, let $a_{n,n+1} \neq 0$ and put $w'_j = w_j - a_{nj} a_{n,n+1}^{-1} w_{n+1}$ for $j \leq n$. These lie in the span of $v_1, \dots, v_{n-1}$, so by induction $\sum_{j \leq n} c_j w'_j = 0$ with some $c_j \neq 0$. Then $\sum_{j \leq n} c_j w_j - \left(\sum_{j \leq n} c_j a_{nj} a_{n,n+1}^{-1}\right) w_{n+1} = 0$ is a nontrivial relation. □

Theorem 8.8.2. *Let R be a nonzero commutative ring. If $R^m \cong R^n$ as R-modules, then $m = n$. In particular any two bases of a finitely generated vector space have the same number of elements.*

Proof. For a field, a basis of n elements generates, so by Lemma 8.8.1 every linearly independent family has at most n elements; hence $k^m \cong k^n$ implies $m \le n$ and $n \le m$. For general R, choose a maximal ideal $\mathfrak{m}$ (Theorem 8.4.3). An isomorphism $R^m \cong R^n$ maps $\mathfrak{m}R^m$ onto $\mathfrak{m}R^n$, so it induces an isomorphism $(R/\mathfrak{m})^m \cong R^m/\mathfrak{m}R^m \cong R^n/\mathfrak{m}R^n \cong (R/\mathfrak{m})^n$ of vector spaces over the field $R/\mathfrak{m}$. □

Definition 8.8.3. For R nonzero commutative, the *rank* of a free module R^n is n.

Theorem 8.8.4. *Let k be a field, V a vector space, $I \subseteq V$ a linearly independent subset and $S \supseteq I$ a generating subset. There is a basis B of V with $I \subseteq B \subseteq S$. In particular every vector space has a basis, every linearly independent subset extends to a basis, and every generating subset contains a basis.*

Proof. Let P be the set of linearly independent subsets J with $I \subseteq J \subseteq S$, ordered by inclusion. The union of a chain in P is linearly independent, since a linear relation involves finitely many vectors, which lie in one member of the chain. By Zorn's lemma (Theorem 3.7.2) there is a maximal $B \in P$. If some $s \in S$ were not a linear combination of B, then $B \cup \{s\}$ would be linearly independent, contradicting maximality. So every element of S, and hence of V, is a linear combination of B. □

Theorem 8.8.5. *Any two bases of a vector space V have the same cardinality, called the* dimension $\dim_k V$.

Proof. Let B and C be bases. If B is finite with n elements, then by Lemma 8.8.1 every linearly independent set has at most n elements, so C is finite, and $|B| = |C|$ by Theorem 8.8.2. Suppose both are infinite. Each $c \in C$ is a linear combination of a finite subset $F_c \subseteq B$. Every $b \in B$ lies in some F_c: otherwise b would be a linear combination of $\bigcup_c F_c \subseteq B \setminus \{b\}$, contradicting independence. So $B = \bigcup_{c \in C} F_c$ and $|B| \le |C|$ by Proposition 3.7.5. By symmetry $|C| \le |B|$, and Theorem 3.6.2 gives $|B| = |C|$. □

Counterexample 8.8.6. Theorem 8.8.2 fails for noncommutative rings. Let k be a field, $V = k^{(\mathbb{N})}$ and $R = \mathrm{End}_k(V)$. Splitting $\mathbb{N}$ into even and odd numbers gives $V \cong V \oplus V$. As a left R-module (by post-composition), $R = \mathrm{Hom}_k(V, V) \cong \mathrm{Hom}_k(V \oplus V, V) \cong \mathrm{Hom}_k(V, V) \oplus \mathrm{Hom}_k(V, V) = R^2$.

8.9 Tensor products

In this section R is a commutative ring.

Definition 8.9.1. Let M, N, P be R-modules. A map $\beta\colon M \times N \to P$ is *bilinear* if it is R-linear in each variable. A *tensor product* of M and N is a module $M \otimes_R N$ with a bilinear map $\otimes\colon M \times N \to M \otimes_R N$, $(m, n) \mapsto m \otimes n$, such that every bilinear $\beta\colon M \times N \to P$ factors as $\beta = \tilde{\beta} \circ \otimes$ for a unique linear $\tilde{\beta}$.

Proposition 8.9.2. *Tensor products exist and are unique up to unique isomorphism. The elements $m \otimes n$ generate $M \otimes_R N$.*

Proof. Uniqueness is the usual argument for universal properties. Let $F = R^{(M \times N)}$ and $Q \subseteq F$ the submodule generated by the elements $e_{(m+m',n)} - e_{(m,n)} - e_{(m',n)}$, $e_{(m,n+n')} - e_{(m,n)} - e_{(m,n')}$, $e_{(rm,n)} - r e_{(m,n)}$ and $e_{(m,rn)} - r e_{(m,n)}$. Put $M \otimes_R N = F/Q$ and $m \otimes n = e_{(m,n)} + Q$. A bilinear β induces a linear map $F \to P$, $e_{(m,n)} \mapsto \beta(m, n)$, vanishing on Q, hence a unique $\tilde{\beta}$. The elements $m \otimes n$ generate since the $e_{(m,n)}$ generate F. □

Proposition 8.9.3. *There are natural isomorphisms $R \otimes_R M \cong M$, $M \otimes N \cong N \otimes M$, $(M \otimes N) \otimes P \cong M \otimes (N \otimes P)$ and $(\bigoplus_i M_i) \otimes N \cong \bigoplus_i (M_i \otimes N)$. In particular $R^m \otimes R^n \cong R^{mn}$. For an ideal I, $(R/I) \otimes_R M \cong M/IM$.*

Proof. Each isomorphism is obtained by constructing maps in both directions from bilinear maps and checking that the composites fix generators $m \otimes n$. For instance $(r, m) \mapsto rm$ induces $R \otimes M \to M$, inverse to $m \mapsto 1 \otimes m$. For associativity, for fixed p the map $(m, n) \mapsto m \otimes (n \otimes p)$ is bilinear, giving $(m \otimes n) \mapsto m \otimes (n \otimes p)$; this is bilinear in $(m \otimes n, p)$, and an inverse is constructed symmetrically. For direct sums, $((m_i), n) \mapsto (m_i \otimes n)$ is bilinear, and the inverse is induced by the maps $M_i \otimes N \to (\bigoplus M_i) \otimes N$. Finally, $(\bar{r}, m) \mapsto \overline{rm}$ induces $R/I \otimes M \to M/IM$, with inverse $\bar{m} \mapsto \bar{1} \otimes m$, well defined since $1 \otimes am = \bar{a} \otimes m = 0$ for $a \in I$. □

Theorem 8.9.4 (Tensor–hom adjunction)**.** *For R-modules M, N, P there is a bijection, natural in all three variables,*

$$\mathrm{Hom}_R(M \otimes_R N, P) \cong \mathrm{Hom}_R(M, \mathrm{Hom}_R(N, P)), \qquad f \mapsto (m \mapsto (n \mapsto f(m \otimes n))).$$

So $- \otimes_R N$ is left adjoint to $\mathrm{Hom}_R(N, -)$. Consequently $- \otimes_R N$ preserves colimits, and for every exact sequence $A \to B \to C \to 0$ the sequence $A \otimes N \to B \otimes N \to C \otimes N \to 0$ is exact.

Proof. Both sides are in bijection with bilinear maps $M \times N \to P$, naturally. The functor $- \otimes_R N$ preserves colimits by Theorem 6.10.4. A sequence $A \xrightarrow{u} B \xrightarrow{v} C \to 0$ is exact if and only if v is a cokernel of u, that is, a coequaliser of u and 0; this is preserved. □

Example 8.9.5. $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/d\mathbb{Z}$ with $d = \gcd(m, n)$, since by Proposition 8.9.3 it is $(\mathbb{Z}/n\mathbb{Z})/m(\mathbb{Z}/n\mathbb{Z}) = \mathbb{Z}/(m, n) = \mathbb{Z}/d\mathbb{Z}$. In particular $\mathbb{Z}/2\mathbb{Z} \otimes \mathbb{Z}/3\mathbb{Z} = 0$, and $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} = 0$ since $x \otimes \bar{1} = nx/n \otimes \bar{1} = x/n \otimes \bar{n} = 0$.

Counterexample 8.9.6. Tensoring does not preserve injectivity. The map $2 \colon \mathbb{Z} \to \mathbb{Z}$ is injective, but tensoring with $\mathbb{Z}/2\mathbb{Z}$ gives the zero map $\mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$. Similarly $\mathrm{Hom}_R(N, -)$ does not preserve surjectivity: $\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ is surjective but $\mathrm{Hom}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}) = 0 \to \mathrm{Hom}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$ is not.

Definition 8.9.7. An R-module N is *flat* if $- \otimes_R N$ preserves injective homomorphisms. Free modules are flat, by Proposition 8.9.3.

Proposition 8.9.8 (Extension of scalars)**.** *Let $\varphi \colon R \to S$ be a homomorphism of commutative rings. For an R-module M, $S \otimes_R M$ is an S-module via $s(s' \otimes m) = ss' \otimes m$, and for every S-module N (an R-module via φ) there is a natural bijection $\mathrm{Hom}_S(S \otimes_R M, N) \cong \mathrm{Hom}_R(M, N)$, $f \mapsto (m \mapsto f(1 \otimes m))$.*

Proof. For $s \in S$, multiplication by s on S is R-linear, so it induces an endomorphism of $S \otimes_R M$; this gives the module structure. Given an R-linear $g \colon M \to N$, the map $(s, m) \mapsto sg(m)$ is R-bilinear and induces an S-linear map $S \otimes M \to N$; the two constructions are inverse because $1 \otimes m$ generate $S \otimes M$ as an S-module. □

8.10 Algebras and graded rings

Definition 8.10.1. Let R be commutative. An *R-algebra* is a ring A with a ring homomorphism $R \to A$ whose image lies in the center of A. Homomorphisms of R-algebras are ring homomorphisms compatible with the maps from R. A *graded ring* is a ring $A = \bigoplus_{n \in \mathbb{Z}} A_n$ (as abelian group) with $A_m A_n \subseteq A_{m+n}$; elements of A_n are *homogeneous of degree n*. A *graded module* over A is a module $M = \bigoplus_n M_n$ with $A_m M_n \subseteq M_{m+n}$. An ideal of a graded ring is *homogeneous* if it is generated by homogeneous elements.

Proposition 8.10.2. *Let A and B be commutative R-algebras. There is a unique ring structure on $A \otimes_R B$ with $(a \otimes b)(a' \otimes b') = aa' \otimes bb'$, and with the maps $a \mapsto a \otimes 1$ and $b \mapsto 1 \otimes b$ it is a coproduct of A and B in the category of commutative R-algebras.*

Proof. For fixed (a', b') the map $(a, b) \mapsto aa' \otimes bb'$ is bilinear, inducing $\mu_{a',b'} : A \otimes B \to A \otimes B$, and $(a', b') \mapsto \mu_{a',b'}$ is bilinear, inducing a bilinear multiplication on $A \otimes B$ with the required formula. Associativity, commutativity and the unit $1 \otimes 1$ hold on generators, hence everywhere by bilinearity. Given algebra homomorphisms $f : A \to C$, $g : B \to C$ to a commutative algebra, the bilinear map $(a, b) \mapsto f(a)g(b)$ induces a linear map $A \otimes B \to C$, which is multiplicative on generators and hence a ring homomorphism; it is unique since the elements $a \otimes b = (a \otimes 1)(1 \otimes b)$ generate. □

Example 8.10.3. The polynomial ring $R[x_1, \ldots, x_n]$ is graded by total degree, with A_d the span of the monomials of degree d. By Proposition 8.10.2 and Proposition 8.6.3, $R[x] \otimes_R R[y] \cong R[x, y]$. Graded rings of this kind are the homogeneous coordinate rings of projective varieties (Chapter 53).

Lemma 8.10.4. *An ideal I of a graded commutative ring A is homogeneous if and only if, for every $f \in I$, all homogeneous components of f lie in I.*

Proof. If I is generated by homogeneous g_j and $f = \sum_j a_j g_j \in I$, then the degree-n component of f is $\sum_j (a_j)_{n-\deg g_j} g_j \in I$. Conversely, if I contains the components of its elements, it is generated by these components. □

8.11 Modules over a principal ideal domain

In this section R is a principal ideal domain.

Proposition 8.11.1. *Every submodule of R^n is free of rank at most n.*

Proof. The proof of Proposition 7.11.4 applies verbatim, using that the image of a submodule under the last coordinate is an ideal (d) of R. □

Theorem 8.11.2 (Smith normal form)**.** *Let M be an $m \times n$ matrix over R. There are invertible matrices P, Q over R such that PMQ is diagonal with entries $d_1, \ldots, d_r, 0, \ldots, 0$, where $d_i \neq 0$ and $d_1 \mid d_2 \mid \cdots \mid d_r$.*

Proof. Since R is a UFD (Theorem 8.5.4), each nonzero $a \in R$ has a *length* $\ell(a)$, the number of prime factors counted with multiplicity; if $d \mid a$ and d is not associate to a, then $\ell(d) < \ell(a)$. Besides row and column swaps and adding multiples of one row (column) to another, we use the following operation: for entries a, b in the same row, in columns i and j, write $d = \gcd(a, b) = xa + yb$ (possible since $(a, b) = (d)$) and replace columns i, j by $x\,\mathrm{col}_i + y\,\mathrm{col}_j$ and $-(b/d)\mathrm{col}_i + (a/d)\mathrm{col}_j$. This is multiplication by an invertible matrix (its 2×2 block has determinant 1), and it replaces a, b by $d, 0$. The same operation exists for rows.

Now argue as in Theorem 7.11.5, with ℓ in place of the absolute value. Among all matrices obtained from M by these operations choose one whose nonzero entry of least length is as short as possible, and move it to position $(1, 1)$. If it did not divide an entry in the first row or column, the operation above would produce a proper divisor, of smaller length. So it divides these entries, and we clear the first row and column. If it did not divide some other entry, adding that row to the first row and applying the operation would again produce a shorter entry. Apply induction to the remaining block. □

Theorem 8.11.3 (Structure theorem). *Let M be a finitely generated R-module. There are $r \geq 0$ and nonzero nonunits $d_1 \mid d_2 \mid \cdots \mid d_k$ in R with*

$$M \cong R^r \oplus R/(d_1) \oplus \cdots \oplus R/(d_k),$$

and r and the ideals $(d_1), \ldots, (d_k)$ are uniquely determined by M.

Proof. Existence is proved exactly as in Theorem 7.11.6, using Proposition 8.11.1 and Theorem 8.11.2. For uniqueness, the torsion submodule $T = \{m : am = 0 \text{ for some } a \neq 0\}$ is $\bigoplus R/(d_i)$, and $M/T \cong R^r$, so r is determined by Theorem 8.8.2. Let p be a prime of R and $j \geq 0$. For $d \neq 0$ with $v = v_p(d)$, the $R/(p)$-vector space $p^j(R/(d))/p^{j+1}(R/(d))$ is one-dimensional if $v \geq j+1$ and zero otherwise: indeed $p^j(R/(d)) = (p^{\min(j,v)})/(d)$. Hence $\dim_{R/(p)} p^jT/p^{j+1}T$ is the number of i with $p^{j+1} \mid d_i$, which by Theorem 8.8.2 depends only on T. As in the proof of Theorem 7.11.6, these numbers determine k and the p-adic valuations of all d_i, hence the d_i up to units. □

Corollary 8.11.4. *Every finitely generated torsion R-module is a direct sum of modules $R/(p^e)$ with p prime and $e \geq 1$, and the multiset of the ideals (p^e) is uniquely determined.*

Proof. Apply Theorem 8.3.3 to $R/(d_i)$ with the prime factorisation of d_i; uniqueness follows from the uniqueness in Theorem 8.11.3, since the d_i are recovered from the prime powers by taking, for each p, the largest powers for d_k, the next largest for d_{k-1}, and so on. □

8.12 Exercises

Exercise 8.12.1. Let k be a field. Show that $M_n(k)$ has no two-sided ideals other than 0 and $M_n(k)$, although it has many left ideals for $n \geq 2$.

Exercise 8.12.2. Show that $\mathbb{Z}[x]/(x^2+1) \cong \mathbb{Z}[i]$, and that $\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$.

Exercise 8.12.3. Show that $(\mathbb{Z}/n\mathbb{Z})^\times$ consists of the classes of integers coprime to n, and deduce Fermat's little theorem: $a^{p-1} \equiv 1 \pmod{p}$ for p prime and $p \nmid a$.

Solution. If $\gcd(a,n) = 1$ then $ax + ny = 1$ by Theorem 4.5.3, so $[a][x] = 1$. If $d = \gcd(a,n) > 1$ then $[a][n/d] = 0$ with $[n/d] \neq 0$, so $[a]$ is a zero divisor and not a unit. For Fermat, apply Theorem 7.3.3 to the group $\mathbb{F}_p^\times$ of order $p-1$. □

Exercise 8.12.4. Let p be prime. Show that $x^{p-1} + x^{p-2} + \cdots + 1$ is irreducible in $\mathbb{Q}[x]$ by applying Proposition 8.6.15 to its image under $x \mapsto x+1$.

Exercise 8.12.5. Compute $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Q}$ and show that $\mathbb{Q}$ is a flat $\mathbb{Z}$-module which is not free.

Exercise 8.12.6. Let k be a field. Show that $k[x,y]$ is a UFD but not a PID.

Exercise 8.12.7. Let k be a field, V a finite-dimensional vector space and $T\colon V \to V$ linear. Using Example 8.7.2 and Theorem 8.11.3, show that $V \cong \bigoplus_i k[x]/(f_i)$ as $k[x]$-modules for monic $f_1 \mid \cdots \mid f_k$, and that f_k is the monic polynomial of least degree with $f_k(T) = 0$.

Chapter 9

Fields and Galois Theory

9.1 Introduction

This chapter studies field extensions: algebraic elements, splitting fields and algebraic closures, separability, the fundamental theorem of Galois theory, finite fields, cyclotomic fields and solvability by radicals. We give Artin's algebraic proof of the fundamental theorem of algebra, and we study transcendence bases, which show that $\mathbb{C}$ has an enormous group of automorphisms. These automorphisms reappear in the theory of absolute Hodge classes (Chapter 75).

References are [Lan02], [Art42] and [Ste15].

Prerequisites. Chapter 4 (Number Systems), Chapter 7 (Groups) and Chapter 8 (Rings and Modules).

On the way to the Hodge conjecture. The direct route uses field extensions and algebraic closures (Sections 9.2, 9.3) and transcendence bases (Section 9.10), which give the dimension of varieties. Galois theory proper (Sections 9.4 to 9.9) is used mainly for algebraic geometry over non-closed fields and in the arithmetic chapters at the end of the book.

9.2 Field extensions

Definition 9.2.1. A *field extension* L/K is a field L together with a subfield K (more generally, a homomorphism of fields $K \to L$, which is injective by Counterexample 6.8.9). Then L is a K-vector space, and its dimension $[L : K] = \dim_K L$ is the *degree* of the extension; the extension is *finite* if the degree is finite. For a subset $S \subseteq L$, $K(S)$ denotes the smallest subfield of L containing K and S, and $K[S]$ the smallest subring; they are obtained from K by *adjoining* S. For a single element, $K[\alpha] = \{f(\alpha) : f \in K[x]\} \cong K[x]/\ker(\mathrm{ev}_\alpha)$ by Proposition 8.6.9, and $K(\alpha)$ consists of the quotients $f(\alpha)/g(\alpha)$ with $g(\alpha) \neq 0$, since these form a subfield and every subfield containing K and α contains them. A *K-homomorphism* between extensions of K is a field homomorphism that is the identity on K; $\mathrm{Aut}(L/K)$ is the group of K-automorphisms of L.

Theorem 9.2.2 (Tower law)**.** *Let $K \subseteq L \subseteq M$ be fields. If $(l_i)_{i\in I}$ is a basis of L over K and $(m_j)_{j\in J}$ a basis of M over L, then $(l_i m_j)_{(i,j)\in I\times J}$ is a basis of M over K. In particular $[M : K] = [M : L][L : K]$.*

Proof. Every $x \in M$ is $\sum_j a_j m_j$ with $a_j \in L$, and each $a_j = \sum_i c_{ij} l_i$ with $c_{ij} \in K$, so the $l_i m_j$ generate. If $\sum_{i,j} c_{ij} l_i m_j = 0$, then $\sum_j (\sum_i c_{ij} l_i) m_j = 0$ gives $\sum_i c_{ij} l_i = 0$ for all j, hence all $c_{ij} = 0$. □

Definition 9.2.3. Let L/K be an extension. An element $\alpha \in L$ is *algebraic* over K if $f(\alpha) = 0$ for some nonzero $f \in K[x]$, and *transcendental* otherwise. The extension is *algebraic* if all elements of L are algebraic over K.

Proposition 9.2.4. *Let $\alpha \in L$ be algebraic over K. The kernel of the evaluation homomorphism $K[x] \to L$, $f \mapsto f(\alpha)$, is generated by a unique monic irreducible polynomial m_α, the* minimal polynomial *of α. The evaluation induces an isomorphism $K[x]/(m_\alpha) \cong K[\alpha]$, so $K[\alpha] = K(\alpha)$ is a field with basis $1, \alpha, \ldots, \alpha^{d-1}$ over K, where $d = \deg m_\alpha = [K(\alpha) : K]$.*

Proof. The kernel is a nonzero ideal of the PID $K[x]$ (Theorem 8.6.6), hence generated by a unique monic polynomial. The image $K[\alpha]$ is a subring of a field, hence a domain, so the kernel is prime, and the generator is irreducible. Nonzero prime ideals of a PID are maximal (proof of Theorem 8.5.4), so $K[\alpha] \cong K[x]/(m_\alpha)$ is a field (Proposition 8.4.2). By division with remainder, the classes of $1, x, \ldots, x^{d-1}$ form a basis of $K[x]/(m_\alpha)$. □

Proposition 9.2.5. *1. An element α is algebraic over K if and only if $[K(\alpha) : K] < \infty$. Every finite extension is algebraic.*

2. If $\alpha_1, \ldots, \alpha_n$ are algebraic over K, then $K(\alpha_1, \ldots, \alpha_n)/K$ is finite. The elements of L algebraic over K form a subfield of L.

3. If L/K and M/L are algebraic, then M/K is algebraic.

Proof. (1) If $[L : K] = n$ is finite and $\alpha \in L$, the $n+1$ elements $1, \alpha, \ldots, \alpha^n$ are linearly dependent, which gives a nonzero polynomial with root α. The rest follows from Proposition 9.2.4. (2) Each α_i is algebraic over $K(\alpha_1, \ldots, \alpha_{i-1})$, so the claim follows from the tower law. If α, β are algebraic, then $\alpha \pm \beta$, $\alpha\beta$ and α^{-1} lie in the finite extension $K(\alpha, \beta)$ and are algebraic by (1). (3) Let $\alpha \in M$ be a root of $c_n x^n + \cdots + c_0$ with $c_i \in L$ not all zero. Then α is algebraic over $K(c_0, \ldots, c_n)$, which is finite over K by (2); so $K(c_0, \ldots, c_n, \alpha)$ is finite over K and α is algebraic by (1). □

Example 9.2.6. $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$, since $x^2 - 2$ is irreducible by Proposition 4.6.4. The real number $\sqrt[3]{2}$ has minimal polynomial $x^3 - 2$, irreducible by Eisenstein's criterion (Proposition 8.6.15), so $[\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 3$. Hence $\sqrt[3]{2} \notin \mathbb{Q}(\sqrt{2})$, by the tower law. Transcendental numbers exist by Exercise 4.11.6.

Proposition 9.2.7 (Kronecker)**.** *Let $f \in K[x]$ be irreducible. Then $L = K[x]/(f)$ is an extension of K of degree* $\deg f$ *in which the class of x is a root of f.*

Proof. (f) is maximal, so L is a field; the composite $K \to K[x] \to L$ is injective, and $f(\bar{x}) = \overline{f(x)} = 0$. The degree is computed as in Proposition 9.2.4. □

9.3 Splitting fields and algebraic closures

Definition 9.3.1. Let $f \in K[x]$ be nonconstant. An extension L/K is a *splitting field* of f if $f = c(x - \alpha_1) \cdots (x - \alpha_n)$ in $L[x]$ and $L = K(\alpha_1, \ldots, \alpha_n)$. A field is *algebraically closed* if every nonconstant polynomial over it has a root, and an *algebraic closure* of K is an algebraic extension that is algebraically closed.

Proposition 9.3.2. *Every nonconstant $f \in K[x]$ has a splitting field L, with $[L : K] \leq (\deg f)!$.*

Proof. By induction on $n = \deg f$. Let g be an irreducible factor of f and $K_1 = K[x]/(g)$, in which f has a root α_1 and $[K_1 : K] \leq n$. Over K_1, $f = (x - \alpha_1) f_1$ with $\deg f_1 = n - 1$; a splitting field of f_1 over K_1 is a splitting field of f over K of degree at most $n \cdot (n-1)!$. □

Theorem 9.3.3 (Extension of homomorphisms)**.** *Let $L = K(\alpha_1, \dots, \alpha_r)$ be a finite extension and $\tau\colon K \to M$ a field homomorphism. The number of homomorphisms $L \to M$ extending τ is at most $[L : K]$. For $i = 1, \dots, r$ let g_i be the minimal polynomial of α_i over $K(\alpha_1, \dots, \alpha_{i-1})$. If for every extension τ' of τ to $K(\alpha_1, \dots, \alpha_{i-1})$ the polynomial $g_i^{\tau'}$ splits into distinct linear factors in $M[x]$, then there are exactly $[L : K]$ extensions.*

Proof. By induction on r, using the tower law, it suffices to treat $r = 1$: $L = K(\alpha)$ with minimal polynomial g. An extension σ of τ is determined by $\sigma(\alpha)$, which is a root of g^τ (the polynomial obtained by applying τ to the coefficients). Conversely, for each root $\beta \in M$ of g^τ, the homomorphism $K[x] \to M$ extending τ with $x \mapsto \beta$ kills g and so induces an extension $K(\alpha) \cong K[x]/(g) \to M$. Hence the extensions correspond to the roots of g^τ in M, of which there are at most $\deg g = [K(\alpha) : K]$ by Corollary 8.6.7, with equality if g^τ splits into distinct linear factors. □

Corollary 9.3.4. *Let L and L' be splitting fields of $f \in K[x]$. Then there is a K-isomorphism $L \to L'$. For every finite extension L/K, $|\operatorname{Aut}(L/K)| \le [L : K]$.*

Proof. Write $L = K(\alpha_1, \dots, \alpha_n)$ with the α_i the roots of f. At each stage the minimal polynomial g_i divides f, and f splits in L', so $g_i^{\tau'}$ has a root in L' and the proof of Theorem 9.3.3 gives at least one extension of the inclusion $K \to L'$ to $\sigma\colon L \to L'$. It is injective, and its image contains all roots of f in L' (it contains n roots counted with multiplicity), so it is L'. The second statement is the first part of Theorem 9.3.3 with $M = L$. □

Theorem 9.3.5. *Every field K has an algebraic closure $\bar{K}$. If L/K is algebraic and $\tau\colon K \to M$ is a homomorphism into an algebraically closed field, then τ extends to $L \to M$. Any two algebraic closures of K are K-isomorphic.*

Proof. Existence (Artin). Let $\mathcal{F}$ be the set of monic nonconstant polynomials in $K[x]$, let $A = K[x_f : f \in \mathcal{F}]$ be the polynomial ring in variables indexed by $\mathcal{F}$ (the union of the polynomial rings in finitely many of them), and I the ideal generated by the $f(x_f)$. Then $I \neq A$: otherwise $1 = \sum_{i=1}^n g_i f_i(x_{f_i})$ for finitely many f_i; in a splitting field of $f_1 \cdots f_n$ choose roots β_i of f_i, and apply the homomorphism $x_{f_i} \mapsto \beta_i$, other variables $\mapsto 0$, to get $1 = 0$. Let $\mathfrak{m} \supseteq I$ be maximal (Theorem 8.4.3) and $E_1 = A/\mathfrak{m}$, a field extension of K in which every $f \in \mathcal{F}$ has a root. Repeating, we get $K = E_0 \subseteq E_1 \subseteq E_2 \subseteq \cdots$ where every nonconstant polynomial over E_n has a root in E_{n+1}. The union E is algebraically closed, since a polynomial over E has coefficients in some E_n. The elements of E algebraic over K form a field $\bar{K}$ (Proposition 9.2.5). If $g \in \bar{K}[x]$ is nonconstant, a root $\alpha \in E$ is algebraic over $\bar{K}$, hence over K, so $\alpha \in \bar{K}$. Thus $\bar{K}$ is an algebraic closure.

Extension. Consider pairs (F, σ) with $K \subseteq F \subseteq L$ a subfield and $\sigma\colon F \to M$ extending τ, ordered by extension. Chains have upper bounds (take unions), so by Zorn's lemma there is a maximal (F, σ). If $\alpha \in L \setminus F$, its minimal polynomial over F maps to a polynomial with a root in M, and Theorem 9.3.3 extends σ to $F(\alpha)$; contradiction. So $F = L$.

Uniqueness. If $\bar{K}$ and $\bar{K}'$ are algebraic closures, extend the inclusion $K \to \bar{K}'$ to $\sigma\colon \bar{K} \to \bar{K}'$. Its image is an algebraically closed field over which $\bar{K}'$ is algebraic, so every element of $\bar{K}'$ is a root of a polynomial that splits over $\sigma(\bar{K})$, and σ is surjective. □

9.4 Separability

Definition 9.4.1. A nonzero polynomial $f \in K[x]$ is *separable* if it has no repeated root in a splitting field. An algebraic element is *separable* if its minimal polynomial is, and an algebraic extension is separable if all its elements are. The *derivative* of $f = \sum a_i x^i$ is $f' = \sum i a_i x^{i-1}$; it satisfies $(fg)' = f'g + fg'$.

Proposition 9.4.2. *A nonzero polynomial f is separable if and only if* $\gcd(f, f') = 1$ *in* $K[x]$. *An irreducible polynomial is separable if and only if* $f' \neq 0$. *If* $\operatorname{char} K = 0$, *every irreducible polynomial is separable; if* $\operatorname{char} K = p > 0$, *an irreducible f is inseparable if and only if* $f = g(x^p)$ *for some* $g \in K[x]$.

Proof. In a splitting field, if $f = (x-\alpha)^2 h$ then $f'(\alpha) = 0$; if $f = (x-\alpha)h$ with $h(\alpha) \neq 0$ then $f'(\alpha) = h(\alpha) \neq 0$. So f has a repeated root iff f and f' have a common root in a splitting field, iff they have a common factor of positive degree in $K[x]$ (a common root α makes m_α a common factor; conversely a common factor has a root in the splitting field). If f is irreducible and $f' \neq 0$, the gcd divides f and has degree $< \deg f$, so it is 1. If $f' = 0$ then $\gcd(f, f') = f$. Finally $f' = 0$ iff $i a_i = 0$ for all i, which in characteristic 0 means f is constant, and in characteristic p means $a_i = 0$ unless $p \mid i$. □

Definition 9.4.3. A field K is *perfect* if it has characteristic 0, or characteristic p and the *Frobenius* $x \mapsto x^p$ is surjective. (The Frobenius is always an injective ring homomorphism in characteristic p, since p divides the binomial coefficients $\binom{p}{i}$ for $0 < i < p$.)

Proposition 9.4.4. *Over a perfect field every irreducible polynomial is separable, so every algebraic extension is separable. Finite fields are perfect.*

Proof. If $\operatorname{char} K = p$ and $f = \sum b_i x^{pi}$ with $b_i = c_i^p$, then $f = (\sum c_i x^i)^p$ is not irreducible. A finite field is perfect because an injective map from a finite set to itself is surjective. □

Counterexample 9.4.5. Let $K = \mathbb{F}_p(t)$ be the field of fractions of $\mathbb{F}_p[t]$. The polynomial $f = x^p - t$ is irreducible, by Eisenstein's criterion for the prime t of the UFD $\mathbb{F}_p[t]$, but $f' = 0$. In a splitting field, with $\beta^p = t$, we have $f = (x-\beta)^p$: a single root of multiplicity p. So K is not perfect and $K(\beta)/K$ is not separable.

9.5 Galois extensions

Definition 9.5.1. An algebraic extension L/K is *normal* if every irreducible polynomial in $K[x]$ with a root in L splits into linear factors in $L[x]$. For a group G of automorphisms of a field L, the *fixed field* is $L^G = \{x \in L : \sigma(x) = x \text{ for all } \sigma \in G\}$.

Lemma 9.5.2 (Artin)**.** *Let G be a finite group of automorphisms of a field L. Then* $[L : L^G] \leq |G|$.

Proof. Let $K = L^G$, $G = \{\sigma_1, \ldots, \sigma_n\}$ with $\sigma_1 = \mathrm{id}$, and let $\alpha_1, \ldots, \alpha_m \in L$ with $m > n$. The m vectors $(\sigma_i(\alpha_j))_i \in L^n$ are linearly dependent over L by Lemma 8.8.1, so the system $\sum_j \sigma_i(\alpha_j) x_j = 0$, $i = 1, \ldots, n$, has a nonzero solution $(x_j) \in L^m$. Choose one with the fewest nonzero entries and, scaling, with $x_{j_0} = 1$ for some j_0. For $\tau \in G$, applying τ gives $\sum_j \tau\sigma_i(\alpha_j)\tau(x_j) = 0$ for all i, and since $\tau\sigma_i$ runs over G as i does, $(\tau(x_j))_j$ is also a solution. The difference $(x_j - \tau(x_j))_j$ is a solution with fewer nonzero entries (the j_0 entry vanishes), so it is zero. Hence all $x_j \in K$, and the equation for $\sigma_1 = \mathrm{id}$ is a nontrivial K-linear relation $\sum_j \alpha_j x_j = 0$. So any $m > n$ elements are linearly dependent over K. □

Theorem 9.5.3. *For a finite extension L/K with $G = \operatorname{Aut}(L/K)$, the following are equivalent:*

1. $|G| = [L : K]$;
2. $L^G = K$;
3. *L is a splitting field over K of a separable polynomial;*
4. *L/K is normal and separable.*

Such an extension is called Galois, *and* $\mathrm{Gal}(L/K) = G$ *its* Galois group. *Moreover, if G is any finite group of automorphisms of a field L, then L/L^G is Galois with group G.*

Proof. For the last statement: $G \subseteq \mathrm{Aut}(L/L^G)$, so by Lemma 9.5.2 and Corollary 9.3.4, $[L : L^G] \leq |G| \leq |\mathrm{Aut}(L/L^G)| \leq [L : L^G]$.

(1) $\Rightarrow$ (2): $K \subseteq L^G$ and by the last statement $[L : L^G] = |G| = [L : K]$, so $L^G = K$ by the tower law.

(2) $\Rightarrow$ (4): Let $\alpha \in L$ and let $\alpha_1, \ldots, \alpha_r$ be the distinct elements of the orbit $G\alpha$. The polynomial $g = \prod_i (x - \alpha_i)$ has coefficients fixed by G, hence in K, and $g(\alpha) = 0$, so $m_\alpha \mid g$. Every $\alpha_i = \sigma(\alpha)$ is a root of m_α, so $g \mid m_\alpha$. Thus $m_\alpha = g$ splits in L with distinct roots.

(4) $\Rightarrow$ (3): Write $L = K(\beta_1, \ldots, \beta_s)$ and let f be the product of the distinct minimal polynomials of the β_j. It is separable (distinct monic irreducible polynomials have no common root), it splits in L by normality, and its roots generate L.

(3) $\Rightarrow$ (1): Apply Theorem 9.3.3 with $M = L$ and τ the inclusion $K \to L$: at every stage the minimal polynomial divides f, which splits into distinct linear factors in L. So there are exactly $[L : K]$ K-homomorphisms $L \to L$. Each is an injective K-linear map of the finite-dimensional K-vector space L to itself, hence bijective by Theorem 8.8.5 (its image is a subspace of the same finite dimension). So $|G| = [L : K]$. □

Theorem 9.5.4 (Fundamental theorem of Galois theory)**.** *Let L/K be a finite Galois extension with group G. The maps $H \mapsto L^H$ and $F \mapsto \mathrm{Gal}(L/F)$ are mutually inverse, inclusion-reversing bijections between subgroups $H \leq G$ and intermediate fields $K \subseteq F \subseteq L$. Moreover $[L : L^H] = |H|$ and $[L^H : K] = [G : H]$. An intermediate field F is Galois over K if and only if $\mathrm{Gal}(L/F)$ is normal in G, and then restriction induces an isomorphism $G/\mathrm{Gal}(L/F) \cong \mathrm{Gal}(F/K)$.*

Proof. If L is the splitting field of a separable $f \in K[x]$, it is also the splitting field of f over F, so L/F is Galois and $L^{\mathrm{Gal}(L/F)} = F$ by Theorem 9.5.3. For $H \leq G$, the last statement of that theorem gives $\mathrm{Gal}(L/L^H) = H$ and $[L : L^H] = |H|$; then $[L^H : K] = [L : K]/|H| = [G : H]$ by the tower law. The maps clearly reverse inclusions.

For $\sigma \in G$, $\mathrm{Gal}(L/\sigma(F)) = \sigma \mathrm{Gal}(L/F)\sigma^{-1}$. If F/K is Galois, it is normal, so σ maps each $\alpha \in F$ to a root of m_α, which lies in F; thus $\sigma(F) = F$ and $\mathrm{Gal}(L/F)$ is normal. Conversely, if $N = \mathrm{Gal}(L/F)$ is normal, then $\sigma(F) = L^{\sigma N \sigma^{-1}} = F$ for all σ, and restriction is a homomorphism $G \to \mathrm{Aut}(F/K)$ with kernel N. Its image has $[G : N] = [F : K]$ elements and lies in a group with at most $[F : K]$ elements (Corollary 9.3.4), so $|\mathrm{Aut}(F/K)| = [F : K]$, F/K is Galois and the restriction map is surjective. □

Example 9.5.5. The field $L = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ is the splitting field of $(x^2 - 2)(x^2 - 3)$, of degree 4 over $\mathbb{Q}$: if $\sqrt{3} = a + b\sqrt{2}$ with $a, b \in \mathbb{Q}$, squaring gives $2ab = 0$, and neither $a = 0$ nor $b = 0$ is possible by the argument of Proposition 4.6.4. Its Galois group consists of the four automorphisms $\sqrt{2} \mapsto \pm\sqrt{2}$, $\sqrt{3} \mapsto \pm\sqrt{3}$, so it is isomorphic to $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. It has three subgroups of order 2, corresponding to the three quadratic subfields $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{3})$ and $\mathbb{Q}(\sqrt{6})$.

Counterexample 9.5.6. The extension $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ of degree 3 is not Galois. A $\mathbb{Q}$-automorphism must send $\sqrt[3]{2}$ to a cube root of 2 in $\mathbb{Q}(\sqrt[3]{2}) \subseteq \mathbb{R}$, and the only real cube root of 2 is $\sqrt[3]{2}$ (Proposition 4.7.4); so the automorphism group is trivial. The polynomial $x^3 - 2$ has a root in $\mathbb{Q}(\sqrt[3]{2})$ but does not split there, so the extension is not normal.

9.6 Finite fields

Lemma 9.6.1. *Every finite subgroup of the multiplicative group of a field is cyclic.*

Proof. Let G be such a subgroup. By Theorem 7.11.6, $G \cong \mathbb{Z}/d_1\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/d_k\mathbb{Z}$ with $d_1 \mid \cdots \mid d_k$, so every element satisfies $x^{d_k} = 1$. The polynomial $x^{d_k} - 1$ has at most d_k roots, so $|G| \le d_k$ and $k \le 1$. □

Theorem 9.6.2. *1. A finite field has $q = p^n$ elements, where p is its characteristic and n its degree over $\mathbb{F}_p$.*

2. For every prime power $q = p^n$ there is a field $\mathbb{F}_q$ with q elements, unique up to isomorphism: a splitting field of $x^q - x$ over $\mathbb{F}_p$, consisting of the roots of this polynomial.

3. $\mathbb{F}_{q^n}/\mathbb{F}_q$ is Galois with cyclic group of order n, generated by the Frobenius $x \mapsto x^q$. The subfields of $\mathbb{F}_{p^n}$ are the $\mathbb{F}_{p^m}$ with $m \mid n$.

Proof. (1) The characteristic is prime by Lemma 8.4.6, and F is a vector space of some finite dimension n over $\mathbb{F}_p$. (2) Let L be a splitting field of $f = x^q - x$. Since $f' = -1$, f has q distinct roots. The set of roots is closed under sums, products and inverses because $x \mapsto x^q$ is a ring homomorphism (a power of the Frobenius), so it is a subfield, and it equals L. If F has q elements, then $F^\times$ has order $q - 1$, so $x^q = x$ for all $x \in F$ by Theorem 7.3.3; hence F is a splitting field of f and $F \cong L$ by Corollary 9.3.4. (3) $\mathbb{F}_{q^n}$ is the splitting field of the separable polynomial $x^{q^n} - x$ over $\mathbb{F}_q$, hence Galois of degree n. The Frobenius $\phi(x) = x^q$ fixes $\mathbb{F}_q$, and $\phi^k = \mathrm{id}$ means all q^n elements are roots of $x^{q^k} - x$, which requires $k \ge n$. So ϕ has order n and generates the Galois group. By the fundamental theorem, subfields correspond to subgroups of $\mathbb{Z}/n\mathbb{Z}$, one for each divisor. □

Theorem 9.6.3 (Primitive element theorem)**.** *Every finite separable extension L/K is* simple*: $L = K(\gamma)$ for some $\gamma \in L$.*

Proof. If K is finite, so is L, and a generator γ of the cyclic group $L^\times$ (Lemma 9.6.1) works. Let K be infinite. By induction on the number of generators it suffices to treat $L = K(\alpha, \beta)$. Let M be a splitting field of $m_\alpha m_\beta$ over L. The minimal polynomials over intermediate fields divide m_α or m_β, which are separable, so by Theorem 9.3.3 there are exactly $n = [L : K]$ distinct K-homomorphisms $\sigma_1, \dots, \sigma_n \colon L \to M$. The polynomial $P(t) = \prod_{i<j}\big((\sigma_i(\alpha) - \sigma_j(\alpha)) + t(\sigma_i(\beta) - \sigma_j(\beta))\big) \in M[t]$ is nonzero, because $\sigma_i \ne \sigma_j$ differ on α or on β. It has finitely many roots, so there is $c \in K$ with $P(c) \ne 0$. Then $\gamma = \alpha + c\beta$ has n distinct images $\sigma_i(\gamma)$. The restrictions of the σ_i to $K(\gamma)$ are therefore distinct, so $[K(\gamma) : K] \ge n$ by Theorem 9.3.3, and $K(\gamma) = L$. □

9.7 The fundamental theorem of algebra

Lemma 9.7.1. *Every polynomial of odd degree in $\mathbb{R}[x]$ has a root in $\mathbb{R}$.*

Proof. We may assume $p = x^n + a_{n-1}x^{n-1} + \cdots + a_0$ is monic, with n odd. Let $M = 1 + \sum_i |a_i|$. For $|x| \ge M$ we have $|a_{n-1}x^{n-1} + \cdots + a_0| \le (M-1)|x|^{n-1} < |x|^n$, so $p(x)$ has the sign of x^n, that is, of x. On $[-M, M]$, the identity $x^i - y^i = (x - y)\sum_k x^k y^{i-1-k}$ gives $|p(x) - p(y)| \le C|x - y|$ with $C = \sum_{i=1}^n i|a_i|M^{i-1}$ (with $a_n = 1$). Let $S = \{x \in [-M, M] : p(x) < 0\}$, which contains $-M$, and $c = \sup S$. If $p(c) < 0$, then $c < M$ and $p < 0$ on $[c, c + |p(c)|/C) \cap [-M, M]$, contradicting $c = \sup S$. If $p(c) > 0$, then $c > -M$ and $p > 0$ on $(c - p(c)/C, c]$, so $\sup S \le c - p(c)/C$, again a contradiction. Hence $p(c) = 0$. □

Lemma 9.7.2. *Every group of order p^n with $n \ge 1$ has a subgroup of index p.*

Proof. By induction on n. By Proposition 7.6.7 and Theorem 7.6.8 there is $z \in Z(G)$ of order p. If $n = 1$ take $\{e\}$. Otherwise $G/\langle z\rangle$ has order p^{n-1} and, by induction, a subgroup of index p, whose preimage in G has index p. □

Theorem 9.7.3 (Fundamental theorem of algebra)**.** *The field $\mathbb{C}$ is algebraically closed.*

Proof. Let $f \in \mathbb{C}[x]$ be nonconstant, and let $\bar{f}$ be obtained by conjugating the coefficients. Then $g = (x^2+1)f\bar{f}$ lies in $\mathbb{R}[x]$. Let L be a splitting field of g over $\mathbb{C}$; it is also a splitting field of g over $\mathbb{R}$ (since $\mathbb{C} = \mathbb{R}(i)$ and i is a root of g), hence Galois over $\mathbb{R}$ as $\operatorname{char}\mathbb{R} = 0$. Let $G = \mathrm{Gal}(L/\mathbb{R})$ and let P be a Sylow 2-subgroup. The fixed field L^P has odd degree $[G:P]$ over $\mathbb{R}$; by Theorem 9.6.3 it is $\mathbb{R}(\gamma)$, and the minimal polynomial of γ is irreducible of odd degree, hence of degree 1 by Lemma 9.7.1. So $P = G$ is a 2-group, and so is $H = \mathrm{Gal}(L/\mathbb{C})$. If $H \neq \{e\}$, it has a subgroup of index 2 (Lemma 9.7.2), whose fixed field is an extension of $\mathbb{C}$ of degree 2, generated by a root of an irreducible quadratic polynomial over $\mathbb{C}$. This contradicts Proposition 4.10.3. So $L = \mathbb{C}$, and f has its roots in $\mathbb{C}$. □

Corollary 9.7.4. *Every nonconstant polynomial over $\mathbb{C}$ is a product of linear factors, and $\mathbb{C}$ is an algebraic closure of $\mathbb{R}$. The irreducible polynomials in $\mathbb{R}[x]$ are the linear ones and the quadratic ones without real roots.*

Proof. The first statement follows by induction on the degree. Since $[\mathbb{C}:\mathbb{R}] = 2$, the extension is algebraic. An irreducible real polynomial of degree ≥ 2 has a non-real root α; then $\bar{\alpha}$ is also a root, and $(x-\alpha)(x-\bar{\alpha}) \in \mathbb{R}[x]$ divides it. □

9.8 Cyclotomic fields

Definition 9.8.1. For $n \geq 1$, the n-th roots of unity in $\mathbb{C}$ form a group μ_n of order n (the polynomial $x^n - 1$ has derivative nx^{n-1}, so its n roots are distinct), cyclic by Lemma 9.6.1. Its generators are the *primitive* n-th roots of unity. The n-th *cyclotomic polynomial* is $\Phi_n = \prod_\zeta (x-\zeta)$ over the primitive n-th roots of unity ζ; it has degree $\varphi(n) = |(\mathbb{Z}/n\mathbb{Z})^\times|$.

Theorem 9.8.2. *Φ_n lies in $\mathbb{Z}[x]$ and is irreducible over $\mathbb{Q}$. The extension $\mathbb{Q}(\zeta)/\mathbb{Q}$ for a primitive n-th root of unity ζ is Galois, and $\sigma \mapsto a_\sigma$, where $\sigma(\zeta) = \zeta^{a_\sigma}$, is an isomorphism $\mathrm{Gal}(\mathbb{Q}(\zeta)/\mathbb{Q}) \cong (\mathbb{Z}/n\mathbb{Z})^\times$.*

Proof. Every n-th root of unity is a primitive d-th root of unity for exactly one $d \mid n$, so $x^n - 1 = \prod_{d|n} \Phi_d$. By induction on n, Φ_n is the quotient of $x^n - 1$ by a monic polynomial in $\mathbb{Z}[x]$, hence lies in $\mathbb{Z}[x]$ by division with remainder.

Let f be the minimal polynomial of ζ over $\mathbb{Q}$. Since $f \mid \Phi_n$ in $\mathbb{Q}[x]$, write $\Phi_n = fg$; by Lemma 8.6.13 (and since f, g are monic) $f, g \in \mathbb{Z}[x]$. Let p be a prime with $p \nmid n$. We claim $f(\zeta^p) = 0$. Otherwise $g(\zeta^p) = 0$, so $f(x) \mid g(x^p)$ in $\mathbb{Z}[x]$. Reducing modulo p and using $\bar{g}(x^p) = \bar{g}(x)^p$ in $\mathbb{F}_p[x]$, we find that $\bar{f}$ and $\bar{g}$ have a common irreducible factor, so $\bar{\Phi}_n = \bar{f}\bar{g}$, and hence $x^n - 1$, has a repeated root in a splitting field over $\mathbb{F}_p$. But the derivative nx^{n-1} is coprime to $x^n - 1$ in $\mathbb{F}_p[x]$, a contradiction. Every primitive root of unity is ζ^a with $\gcd(a,n) = 1$, and writing a as a product of primes not dividing n, repeated application of the claim shows that ζ^a is a root of f. So $f = \Phi_n$.

$\mathbb{Q}(\zeta)$ contains all n-th roots of unity (powers of ζ), so it is the splitting field of $x^n - 1$, hence Galois. Each σ maps ζ to a primitive root ζ^{a_σ}, and $\sigma \mapsto a_\sigma$ is an injective homomorphism into $(\mathbb{Z}/n\mathbb{Z})^\times$, surjective since $|\mathrm{Gal}| = \deg \Phi_n = \varphi(n)$. □

9.9 Solvability by radicals

In this section all fields have characteristic 0.

Definition 9.9.1. A *radical extension* of K is an extension E/K with a chain $K = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_r = E$ where $E_{i+1} = E_i(a_i)$ and $a_i^{n_i} \in E_i$ for some $n_i \geq 1$. A polynomial $f \in K[x]$ is *solvable by radicals* if a splitting field of f is contained in a radical extension of K.

Lemma 9.9.2. *Let K contain a primitive n-th root of unity ω and let b in an extension satisfy $b^n = a \in K$. Then $K(b)/K$ is Galois with cyclic Galois group. For any K and $m \geq 1$, the splitting field of $x^m - 1$ over K is Galois with abelian Galois group.*

Proof. If $b = 0$ there is nothing to prove. Otherwise the roots of $x^n - a$ are the distinct $\omega^i b$, all in $K(b)$, so $K(b)$ is a splitting field of a separable polynomial. Each σ satisfies $\sigma(b) = \omega^{k_\sigma} b$, and since σ fixes ω, $\sigma \mapsto \omega^{k_\sigma}$ is an injective homomorphism into the cyclic group generated by ω. For the second statement, the roots of $x^m - 1$ form a cyclic group generated by some ζ (Lemma 9.6.1; they are distinct in characteristic 0), and $\sigma(\zeta) = \zeta^{a_\sigma}$ defines an injective homomorphism into the abelian group $(\mathbb{Z}/m\mathbb{Z})^\times$. □

Theorem 9.9.3 (Galois)**.** *If $f \in K[x]$ is solvable by radicals, then the Galois group of a splitting field of f over K is solvable.*

Proof. Let $L \subseteq E$ be a splitting field of f inside a radical extension with data a_i, n_i as in Definition 9.9.1. Let $m = n_0 \cdots n_{r-1}$, $h = (x^m - 1) \prod_i m_{a_i}$, and let N be a splitting field of h over E (Proposition 9.3.2). Since E is generated over K by roots of h, N is also a splitting field of h over K. Then N/K is Galois with group G, and N is generated over K by a primitive m-th root of unity ζ and the elements $\sigma(a_i)$, $\sigma \in G$, since the roots of m_{a_i} are the $\sigma(a_i)$ (proof of Theorem 9.5.3). Adjoin these generators in the order ζ, then all $\sigma(a_0)$, then all $\sigma(a_1)$, and so on, obtaining a chain $K = F_0 \subseteq F_1 = K(\zeta) \subseteq F_2 \subseteq \cdots \subseteq F_s = N$. Each $F_{j+1} = F_j(b)$ with F_1/F_0 abelian Galois, and for $j \geq 1$, $b = \sigma(a_i)$ with $b^{n_i} = \sigma(a_i^{n_i})$ in F_j (because $a_i^{n_i} \in E_i = K(a_0, \ldots, a_{i-1})$) and F_j containing a primitive n_i-th root of unity. By Lemma 9.9.2 each F_{j+1}/F_j is Galois with abelian group. By the fundamental theorem, $G_j = \mathrm{Gal}(N/F_j)$ satisfies $G_{j+1} \trianglelefteq G_j$ and $G_j/G_{j+1} \cong \mathrm{Gal}(F_{j+1}/F_j)$ is abelian; so G is solvable (Proposition 7.9.3), and so is its quotient $\mathrm{Gal}(L/K) \cong G/\mathrm{Gal}(N/L)$. □

Remark 9.9.4. The converse also holds: if the Galois group is solvable, then f is solvable by radicals. The proof uses Hilbert's Theorem 90 to show that cyclic extensions of fields containing enough roots of unity are generated by radicals; see [Lan02, Chapter VI, §7].

Lemma 9.9.5. *Let p be prime and $G \leq S_p$ a subgroup acting transitively on $\{1, \ldots, p\}$ and containing a transposition. Then $G = S_p$.*

Proof. The orbit has size p, so p divides $|G|$ (Theorem 7.6.2) and G contains an element of order p (Theorem 7.6.8), necessarily a p-cycle σ. Let $(a\ b) \in G$. Some power of σ sends a to b and is again a p-cycle; renumbering, we may assume it is $(1\,2\,\cdots\,p)$ and the transposition is $(1\,2)$. Conjugating $(1\,2)$ by powers of the p-cycle gives all $(i\ i{+}1)$, and these generate S_p since $(i\ j) = (j{-}1\ j)(i\ j{-}1)(j{-}1\ j)$ recursively. □

Example 9.9.6. The polynomial $f = x^5 - 4x + 2$ is not solvable by radicals over $\mathbb{Q}$. It is irreducible by Eisenstein's criterion at $p = 2$. Its roots in $\mathbb{C}$ (Theorem 9.7.3) satisfy $\sum \alpha_i = 0$ and $\sum_{i<j} \alpha_i \alpha_j = 0$ (the coefficients of x^4 and x^3 vanish), so $\sum \alpha_i^2 = 0$; hence not all roots are real. Since $f(-2) < 0 < f(0)$, $f(1) < 0 < f(2)$, the proof of Lemma 9.7.1 gives real roots in $(-2, 0)$, $(0, 1)$ and $(1, 2)$. Non-real roots come in conjugate pairs, so there are exactly 3 real and 2 non-real roots. Complex conjugation restricts to an element of the Galois group G of the splitting field in $\mathbb{C}$ that exchanges the two non-real roots and fixes the others: a transposition. G acts transitively on the roots (they are roots of one irreducible polynomial, and Theorem 9.3.3 moves any root to any other). By Lemma 9.9.5, $G \cong S_5$, which is not solvable (Proposition 7.9.3).

9.10 Transcendence bases

Definition 9.10.1. Let L/K be an extension. A subset $S \subseteq L$ is *algebraically independent* over K if for all distinct $s_1, \dots, s_n \in S$ the homomorphism $K[x_1, \dots, x_n] \to L$, $x_i \mapsto s_i$, is injective. A *transcendence basis* is an algebraically independent set S such that L is algebraic over $K(S)$. An extension is *purely transcendental* if $L = K(S)$ for an algebraically independent S.

Lemma 9.10.2. *Let $S \subseteq L$ be algebraically independent over K and $\alpha \in L$. Then $S \cup \{\alpha\}$ is algebraically independent if and only if $\alpha \notin S$ and α is transcendental over $K(S)$.*

Proof. A nonzero polynomial relation $P(s_1, \dots, s_n, \alpha) = 0$ with $P \notin K[x_1, \dots, x_n]$ is, after collecting powers of α, a nonzero polynomial over $K[s_1, \dots, s_n] \cong K[x_1, \dots, x_n]$ with root α; and conversely a nonzero polynomial over $K(S)$ with root α can be cleared of denominators to give such a relation. □

Theorem 9.10.3. *Every extension L/K has a transcendence basis, and any two have the same cardinality, the* transcendence degree $\operatorname{trdeg}_K L$. *More precisely, if $T \subseteq L$ is such that L is algebraic over $K(T)$ and $S_0 \subseteq T$ is algebraically independent, then there is a transcendence basis S with $S_0 \subseteq S \subseteq T$.*

Proof. By Zorn's lemma choose a maximal algebraically independent subset S with $S_0 \subseteq S \subseteq T$. By Lemma 9.10.2 every $t \in T$ is algebraic over $K(S)$, so $K(T)$ is algebraic over $K(S)$ and L is algebraic over $K(S)$ by Proposition 9.2.5.

We use the following fact: if F is a field, s is algebraic over $F(t)$ but not over F, then t is algebraic over $F(s)$. Indeed, clearing denominators gives a nonzero $P = \sum_k P_k(X)Y^k \in F[X, Y]$ with $P(s, t) = 0$; not all $P_k(s)$ vanish, since otherwise all $P_k = 0$ as s is transcendental over F; so t is a root of the nonzero polynomial $\sum_k P_k(s)Y^k$.

Let S and T be transcendence bases. Suppose first $T = \{t_1, \dots, t_n\}$ is finite and let $s_1, \dots, s_m \in S$ be distinct. Suppose that after $i < m$ steps L is algebraic over $K(s_1, \dots, s_i, T_i)$ with $T_i \subseteq T$ of size $n - i$. Then s_{i+1} is algebraic over this field; let $T' \subseteq T_i$ be minimal such that s_{i+1} is algebraic over $K(s_1, \dots, s_i, T')$. Since s_{i+1} is not algebraic over $K(s_1, \dots, s_i)$, T' is nonempty; pick $t \in T'$ and let $F = K(s_1, \dots, s_i, T' \setminus \{t\})$. By the fact above, t is algebraic over $F(s_{i+1})$, so with $T_{i+1} = T_i \setminus \{t\}$ the field $K(s_1, \dots, s_i, T_i)$ is algebraic over $K(s_1, \dots, s_{i+1}, T_{i+1})$, and so is L. In particular $T_i \neq \emptyset$ at every step $i < m$, so $m \leq n$. Hence S is finite with $|S| \leq |T|$, and by symmetry $|S| = |T|$.

If both are infinite, each $t \in T$ is algebraic over $K(S_t)$ for a finite $S_t \subseteq S$, and $S' = \bigcup_t S_t$ satisfies $|S'| \leq |T|$ by Proposition 3.7.5. Then L is algebraic over $K(S')$, so every $s \in S$ is algebraic over $K(S')$, which forces $S' = S$ by Lemma 9.10.2. So $|S| \leq |T|$, and by symmetry the cardinalities agree. □

Theorem 9.10.4. *Let Ω and Ω' be algebraically closed fields of the same characteristic, with prime fields $P \subseteq \Omega$ and $P' \subseteq \Omega'$, and $\operatorname{trdeg}_P \Omega = \operatorname{trdeg}_{P'} \Omega'$. Then every bijection between transcendence bases $B \to B'$ extends to an isomorphism $\Omega \to \Omega'$.*

Proof. The prime fields are isomorphic ($\mathbb{Q}$ or $\mathbb{F}_p$). A bijection $B \to B'$ induces an isomorphism of polynomial rings $P[B] \cong P'[B']$ and hence of their fields of fractions $P(B) \cong P'(B')$. The field Ω is an algebraic closure of $P(B)$ and Ω' one of $P'(B')$, so by Theorem 9.3.5 the isomorphism extends to an isomorphism $\Omega \to \Omega'$. □

Corollary 9.10.5. $\operatorname{trdeg}_{\mathbb{Q}} \mathbb{C} = 2^{\aleph_0}$. *If $\alpha, \beta \in \mathbb{C}$ are both transcendental over $\mathbb{Q}$, there is a field automorphism σ of $\mathbb{C}$ with $\sigma(\alpha) = \beta$. Every automorphism of the algebraic closure $\bar{\mathbb{Q}}$ of $\mathbb{Q}$ in $\mathbb{C}$ extends to an automorphism of $\mathbb{C}$.*

Proof. If B is a transcendence basis, $\mathbb{C}$ is algebraic over $\mathbb{Q}(B)$, and a field algebraic over a field of infinite cardinality κ has cardinality κ (each element is a root of one of κ polynomials, each with finitely many roots); $\mathbb{Q}(B)$ has cardinality $\max(|B|, \aleph_0)$. Since $|\mathbb{C}| = 2^{\aleph_0}$ (Proposition 4.8.6) is uncountable, $|B| = 2^{\aleph_0}$. Extend $\{\alpha\}$ and $\{\beta\}$ to transcendence bases B, B' (Theorem 9.10.3 with $T = \mathbb{C}$ and $S_0 = \{\alpha\}$, respectively $S_0 = \{\beta\}$); both have cardinality $2^{\aleph_0}$, and removing α and β leaves sets of the same cardinality, so there is a bijection $B \to B'$ with $\alpha \mapsto \beta$. Apply Theorem 9.10.4. For the last statement, choose a transcendence basis B of $\mathbb{C}$ over $\bar{\mathbb{Q}}$ (it is also one over $\mathbb{Q}$), extend the automorphism to $\bar{\mathbb{Q}}(B)$ by fixing B, and then to $\mathbb{C}$ by Theorem 9.3.5. □

Remark 9.10.6. The automorphisms of Corollary 9.10.5 are constructed with the axiom of choice, and apart from the identity and complex conjugation they are not continuous (Exercise 4.11.3 shows that the only ones fixing $\mathbb{R}$ are these two). They nevertheless act on algebraic varieties defined over $\mathbb{C}$ by acting on coefficients, and the question of how they interact with Hodge theory is the subject of Chapter 75.

Remark 9.10.7. For an algebraic extension L/K that is normal and separable but infinite, $\mathrm{Gal}(L/K)$ is the inverse limit of the finite groups $\mathrm{Gal}(F/K)$ over finite Galois subextensions F, and the fundamental theorem holds for closed subgroups with respect to the resulting profinite topology; see [Lan02, Chapter VI, §14]. Topological groups are introduced in Chapter 18.

9.11 Exercises

Exercise 9.11.1. Show that the splitting field of $x^3 - 2$ over $\mathbb{Q}$ is $\mathbb{Q}(\sqrt[3]{2}, \omega)$ with $\omega = (-1+\sqrt{-3})/2$, that it has degree 6, and that its Galois group is isomorphic to S_3. Describe all intermediate fields.

Exercise 9.11.2. Show that if $\alpha \in \mathbb{R}$ lies in a tower $\mathbb{Q} = K_0 \subseteq \cdots \subseteq K_r$ with $[K_{i+1} : K_i] = 2$, then $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ is a power of 2. Deduce that $\sqrt[3]{2}$ is not in any such tower (impossibility of doubling the cube).

Exercise 9.11.3. Show that for every $n \geq 1$ there is an irreducible polynomial of degree n over $\mathbb{F}_p$, and that $x^{p^n} - x$ is the product of all monic irreducible polynomials over $\mathbb{F}_p$ of degree dividing n.

Exercise 9.11.4. Let G be a group and $\chi_1, \dots, \chi_n \colon G \to L^\times$ distinct homomorphisms into the multiplicative group of a field. Show that the χ_i are linearly independent over L as maps $G \to L$.

Exercise 9.11.5. Let k be a field and $G \leq \mathrm{Aut}(k(t)/k)$ the group of order 2 generated by $t \mapsto 1/t$. Show that $k(t)^G = k(t + 1/t)$.

Exercise 9.11.6. Show that $\bar{\mathbb{Q}}$ is countable and that $\mathrm{trdeg}_{\bar{\mathbb{Q}}} \mathbb{C} = 2^{\aleph_0}$.

Chapter 10

Elementary Number Theory

10.1 Introduction

Number theory studies the integers, and above all the way they are built multiplicatively out of primes. The foundations are already in place: divisibility, greatest common divisors, Bézout's theorem and unique factorisation into primes were proved in Chapter 4, the theorems of Euler, Fermat and Wilson in Chapter 7, the Chinese remainder theorem in Chapters 7 and 8, and the structure of finite fields in Chapter 9. This chapter puts these tools to work on the classical questions of elementary number theory:

1. How does one compute with congruences, and which linear congruences and systems of congruences can be solved (Section 10.2)? As an application we explain the RSA cryptosystem.

2. For which n is the group of units modulo n cyclic, that is, when is there a *primitive root* modulo n (Section 10.3)?

3. Which integers are squares modulo a prime p? The answer is governed by the *law of quadratic reciprocity*, which relates the question "is p a square modulo q?" to the question "is q a square modulo p?" (Section 10.4).

4. Which integers are sums of two squares, and why is every positive integer a sum of four squares (Section 10.5)?

5. How do the multiplicative functions φ, the number of divisors and the sum of divisors behave, and how does Möbius inversion work (Section 10.6)? As an application we determine the even perfect numbers.

6. What are the primes of the Gaussian integers $\mathbb{Z}[i]$ and of the Eisenstein integers $\mathbb{Z}[\omega]$, in how many ways is n a sum of two squares, and how can unique factorisation fail (Section 10.7)?

7. Which primes are of the form $x^2 + 2y^2$, $x^2 + 5y^2$, $x^2 + 7y^2$? Gauss's reduction theory of binary quadratic forms and the class number answer such questions, and explain why $n^2 + n + 41$ is prime for $0 \le n \le 39$; this leads to the Heegner numbers $1, 2, 3, 7, 11, 19, 43, 67, 163$ (Section 10.8).

The theme running through the chapter is that questions about the integers become questions about finite groups and rings, $\mathbb{Z}/n\mathbb{Z}$ and its group of units, or about larger rings such as the Gaussian integers $\mathbb{Z}[i]$, where the answers are visible. This point of view leads to algebraic

number theory, and, through the zeta functions of varieties over finite fields, to the arithmetic side of Hodge theory (Chapters 65 and 76).

References: [IR90], [Ser73] and [HW08].

Prerequisites. Chapter 4 (Number Systems), Chapter 7 (Groups), Chapter 8 (Rings and Modules) and Chapter 9 (Fields and Galois Theory).

On the way to the Hodge conjecture. No later chapter depends on this one; it can be skipped entirely.

10.2 Congruences

Gauss introduced congruences in 1801 as a notation that lets one compute with remainders as if they were numbers. The idea is that many questions about integers only depend on remainders: an integer is even or odd according to its remainder modulo 2, the last digit of a number is its remainder modulo 10, and the day of the week of a date is a remainder modulo 7.

Definition 10.2.1. Let $n \geq 1$. Integers a and b are *congruent modulo* n, written $a \equiv b \pmod{n}$, if $n \mid a - b$. The *residue class* of a is $\bar{a} = a + n\mathbb{Z}$, and $\mathbb{Z}/n\mathbb{Z} = \{\bar{0}, \bar{1}, \ldots, \overline{n-1}\}$ is the quotient ring of $\mathbb{Z}$ by the ideal $n\mathbb{Z}$ (Theorem 8.3.2). We write $U_n = (\mathbb{Z}/n\mathbb{Z})^\times$ for its group of units and $\varphi(n) = |U_n|$; the function φ is *Euler's function*.

Congruence modulo n is an equivalence relation, its classes are the residue classes, and by division with remainder (Theorem 4.5.2) every integer is congruent to exactly one of $0, 1, \ldots, n-1$, its *least non-negative residue*. That $\mathbb{Z}/n\mathbb{Z}$ is a ring says that congruences can be added and multiplied: if $a \equiv a'$ and $b \equiv b'$, then $a + b \equiv a' + b'$ and $ab \equiv a'b' \pmod{n}$. Directly, $ab - a'b' = a(b - b') + (a - a')b'$. So in a computation modulo n we may at any moment replace a number by any other number congruent to it.

Example 10.2.2.

1. *Casting out nines.* Since $10 \equiv 1 \pmod{9}$, also $10^k \equiv 1$, so a number $\sum_k d_k 10^k$ with digits d_k is congruent modulo 9 to the sum $\sum_k d_k$ of its digits. For instance $2026 \equiv 2 + 0 + 2 + 6 = 10 \equiv 1 \pmod{9}$. Similarly $10 \equiv -1 \pmod{11}$, so a number is congruent modulo 11 to the alternating sum of its digits, starting from the last one: $2026 \equiv 6 - 2 + 0 - 2 = 2 \pmod{11}$.

2. *Squares modulo* 4 *and* 8. Every integer is congruent to $0, 1, 2$ or 3 modulo 4, with squares $0, 1, 0, 1$. So a square is congruent to 0 or 1 modulo 4, and a sum of two squares is never congruent to 3 modulo 4: none of $3, 7, 11, 2027$ is a sum of two squares. Similarly the squares of odd numbers are $\equiv 1 \pmod{8}$, since $(2m+1)^2 = 4m(m+1) + 1$ and $m(m+1)$ is even.

3. *Large powers.* To compute 3^{100} modulo 7: $3^2 = 9 \equiv 2$, $3^3 \equiv 6 \equiv -1$, so $3^6 \equiv 1$ and $3^{100} = (3^6)^{16} 3^4 \equiv 3^4 = 81 \equiv 4 \pmod{7}$.

The units of $\mathbb{Z}/n\mathbb{Z}$ are described by Bézout's theorem.

Proposition 10.2.3. *Let $n \geq 1$ and $a \in \mathbb{Z}$.*

1. *$\bar{a}$ is a unit of $\mathbb{Z}/n\mathbb{Z}$ if and only if $\gcd(a, n) = 1$. So $\varphi(n)$ is the number of $0 \leq a < n$ with $\gcd(a, n) = 1$, as in Corollary 7.3.5.*

2. *$\mathbb{Z}/n\mathbb{Z}$ is a field if and only if n is prime. For a prime p we write $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$.*

Proof. (1) If $\gcd(a,n)=1$, Bézout's theorem (Theorem 4.5.3) gives $ax+ny=1$, so $\bar{a}\bar{x}=\bar{1}$. Conversely, if $ax\equiv 1 \pmod{n}$, then $ax+ny=1$ for some y, and every common divisor of a and n divides 1.

(2) $\mathbb{Z}/1\mathbb{Z}$ is the zero ring, which is not a field. For $n\geq 2$, $\mathbb{Z}/n\mathbb{Z}$ is a field if and only if every $\bar{a}\neq 0$, that is every $1\leq a\leq n-1$, is a unit, which by (1) means that $\gcd(a,n)=1$ for $1\leq a<n$. This holds if n is prime, since a positive divisor of n less than n is 1; and it fails if $n=bc$ with $1<b<n$, since $\gcd(b,n)=b$. □

(The notation $\mathbb{F}_p$ is that of Theorem 9.6.2, of which $\mathbb{Z}/p\mathbb{Z}$ is the case $q=p$.) The proof of (1) is constructive: the inverse of a modulo n is found with the Euclidean algorithm (Example 4.5.7), run backwards to express 1 as $ax+ny$.

Proposition 10.2.4 (Linear congruences)**.** *Let $n\geq 1$, $a,b\in\mathbb{Z}$, and $d=\gcd(a,n)$ (with $d=n$ if $a=0$). The congruence $ax\equiv b \pmod{n}$ has a solution if and only if $d\mid b$. In that case its solutions form exactly d residue classes modulo n, namely $x_0+k\frac{n}{d}$ for $k=0,1,\ldots,d-1$, where x_0 is any one solution.*

Proof. If $ax-b=ny$, then d divides $ax-ny=b$. Conversely, if $d\mid b$, write $d=ax_1+ny_1$ by Bézout's theorem; then $x_0=x_1b/d$ satisfies $ax_0=b-ny_1b/d\equiv b$. Let x_0 be a solution. Then x is a solution if and only if $n\mid a(x-x_0)$, that is, $\frac{n}{d}\mid\frac{a}{d}(x-x_0)$. Since $\gcd(\frac{a}{d},\frac{n}{d})=1$ (a common divisor $e>1$ would make de a common divisor of a and n), this means $\frac{n}{d}\mid x-x_0$, by Euclid's lemma in the form: if $m\mid uv$ and $\gcd(m,u)=1$, then $m\mid v$ (from $1=mr+us$, $v=mvr+uvs$). So the solutions are the $x\equiv x_0 \pmod{n/d}$, which modulo n are the d distinct classes x_0+kn/d, $0\leq k<d$. □

Example 10.2.5.

1. $6x\equiv 5 \pmod{10}$ has no solution, since $\gcd(6,10)=2\nmid 5$: indeed $6x$ is even and $10y+5$ is odd.

2. $6x\equiv 4 \pmod{10}$: here $d=2$, and dividing by 2 gives $3x\equiv 2 \pmod{5}$. The inverse of 3 modulo 5 is 2, so $x\equiv 4 \pmod{5}$, and modulo 10 the solutions are $x\equiv 4$ and $x\equiv 9$. Check: $24=2\cdot 10+4$ and $54=5\cdot 10+4$.

3. $17x\equiv 1 \pmod{60}$: the Euclidean algorithm gives $60=3\cdot 17+9$, $17=9+8$, $9=8+1$, so $1=9-8=9-(17-9)=2\cdot 9-17=2(60-3\cdot 17)-17=2\cdot 60-7\cdot 17$. Hence $x\equiv -7\equiv 53 \pmod{60}$; indeed $17\cdot 53=901=15\cdot 60+1$.

Next, several congruences at once. A problem in the Chinese mathematical text of Sunzi (around the fourth century) asks for a number which leaves remainder 2 when divided by 3, remainder 3 when divided by 5 and remainder 2 when divided by 7.

Theorem 10.2.6 (Chinese remainder theorem for integers)**.** *Let $n_1,\ldots,n_k\geq 1$ be pairwise coprime and $N=n_1\cdots n_k$. For all $a_1,\ldots,a_k\in\mathbb{Z}$ the system*

$$x\equiv a_1 \pmod{n_1},\quad \ldots,\quad x\equiv a_k \pmod{n_k}$$

has a solution, unique modulo N. Explicitly, put $N_i=N/n_i$ and choose y_i with $N_iy_i\equiv 1 \pmod{n_i}$; then $x=\sum_i a_iN_iy_i$ is a solution. Consequently the map $\mathbb{Z}/N\mathbb{Z}\to\mathbb{Z}/n_1\mathbb{Z}\times\cdots\times\mathbb{Z}/n_k\mathbb{Z}$, $\bar{x}\mapsto(x \bmod n_1,\ldots,x \bmod n_k)$, is an isomorphism of rings, and restricts to an isomorphism of groups $U_N\cong U_{n_1}\times\cdots\times U_{n_k}$.

Proof. N_i is a product of integers coprime to n_i, so it is coprime to n_i (a prime dividing n_i and N_i would divide some n_j, $j\neq i$, by Lemma 4.5.4), and y_i exists by Proposition 10.2.3. For $j\neq i$, $n_j\mid N_i$; so $x\equiv a_jN_jy_j\equiv a_j \pmod{n_j}$. If x and x' are two solutions, each n_j divides $x-x'$, hence so does N: by induction, if $n_1\cdots n_{j-1}$ and n_j divide m and are coprime, write

$m = n_1 \cdots n_{j-1} m'$; then $n_j \mid n_1 \cdots n_{j-1} m'$ gives $n_j \mid m'$, by Euclid's lemma in the form used in the proof of Proposition 10.2.4. So the ring homomorphism of the statement is bijective. A ring isomorphism maps units onto units, and the units of a product of rings are the elements all of whose components are units. □

This is the special case $R = \mathbb{Z}$ of Theorem 8.3.3, made explicit.

Example 10.2.7. In Sunzi's problem $N = 105$, $N_1 = 35 \equiv 2 \pmod 3$, $N_2 = 21 \equiv 1 \pmod 5$ and $N_3 = 15 \equiv 1 \pmod 7$, so we may take $y_1 = 2$, $y_2 = 1$, $y_3 = 1$, and $x = 2 \cdot 35 \cdot 2 + 3 \cdot 21 + 2 \cdot 15 = 233 \equiv 23 \pmod{105}$. The answer is 23, and the solutions are the numbers $23 + 105m$.

Euler's function can now be computed.

Proposition 10.2.8. *1. If* $\gcd(m, n) = 1$, *then* $\varphi(mn) = \varphi(m)\varphi(n)$.

2. For a prime p *and* $k \geq 1$, $\varphi(p^k) = p^k - p^{k-1} = p^{k-1}(p-1)$.

3. If $n = p_1^{k_1} \cdots p_r^{k_r}$ *with distinct primes* p_i, *then* $\varphi(n) = n \prod_i \left(1 - \frac{1}{p_i}\right)$.

4. (Gauss) $\sum_{d \mid n} \varphi(d) = n$, *the sum running over the positive divisors of* n.

Proof. (1) is the isomorphism $U_{mn} \cong U_m \times U_n$ of Theorem 10.2.6. (2) An integer is coprime to p^k if and only if p does not divide it (its gcd with p^k is a power of p, by Theorem 4.5.5); among $0, \ldots, p^k - 1$ the multiples of p are the p^{k-1} numbers $0, p, \ldots, p^k - p$. (3) follows from (1) and (2), since the prime powers $p_i^{k_i}$ are pairwise coprime: $\varphi(n) = \prod_i p_i^{k_i}(1 - 1/p_i)$.

(4) Sort the integers $1 \leq a \leq n$ according to $\gcd(a, n)$, which is a divisor e of n. Those with $\gcd(a, n) = e$ are the $a = eb$ with $1 \leq b \leq n/e$ and $\gcd(b, n/e) = 1$, and there are $\varphi(n/e)$ of them ($\varphi(1) = 1$ counts $b = 1$). Hence $n = \sum_{e \mid n} \varphi(n/e) = \sum_{d \mid n} \varphi(d)$, as $d = n/e$ runs over the divisors of n when e does. □

Example 10.2.9. $\varphi(12) = 12(1 - \frac{1}{2})(1 - \frac{1}{3}) = 4$, the units modulo 12 being $1, 5, 7, 11$. The divisors of 12 are $1, 2, 3, 4, 6, 12$, and φ of them are $1, 1, 2, 2, 2, 4$, with sum 12. Also $\varphi(100) = 100 \cdot \frac{1}{2} \cdot \frac{4}{5} = 40$, so by Euler's theorem $a^{40} \equiv 1 \pmod{100}$ for a coprime to 10: for instance the last two digits of 3^{2026} are those of $3^{2026 - 50 \cdot 40} = 3^{26}$; and $3^5 = 243 \equiv 43$, $3^{10} \equiv 43^2 = 1849 \equiv 49$, $3^{20} \equiv 49^2 = 2401 \equiv 1 \pmod{100}$, so $3^{26} \equiv 3^6 = 729 \equiv 29$. The last two digits of 3^{2026} are 29.

The last computation used *repeated squaring*: a^e modulo n is computed with about $2 \log_2 e$ multiplications of numbers less than n, by squaring repeatedly and multiplying together the squares a^{2^j} corresponding to the binary digits of e. By contrast no efficient method is known to factor a large integer into primes. The RSA cryptosystem (Rivest, Shamir and Adleman, 1977) is built on this asymmetry.

Proposition 10.2.10 (RSA)**.** *Let* $p \neq q$ *be primes,* $n = pq$, *and let* $e, d \geq 1$ *satisfy* $ed \equiv 1 \pmod{(p-1)(q-1)}$. *Then* $m^{ed} \equiv m \pmod n$ *for every integer* m.

Proof. By Theorem 10.2.6 it suffices to prove the congruence modulo p and modulo q; by symmetry, modulo p. Write $ed = 1 + k(p-1)(q-1)$ with $k \geq 0$. If $p \mid m$, both sides are $\equiv 0$. Otherwise $m^{p-1} \equiv 1 \pmod p$ by Fermat's theorem (Corollary 7.3.5), and $m^{ed} = m \cdot (m^{p-1})^{k(q-1)} \equiv m \pmod p$. □

In practice someone chooses two large primes p and q (several hundred digits each), publishes $n = pq$ and an exponent e coprime to $(p-1)(q-1)$, and keeps secret the inverse d of e modulo $(p-1)(q-1)$, computed with the Euclidean algorithm. Anyone can encrypt a message $0 \leq m < n$ as $c \equiv m^e \pmod n$, and by the proposition the owner decrypts it as $m \equiv c^d \pmod n$. Computing d from n and e is as hard as factoring n (Exercise 10.9.11 shows

that knowing $(p-1)(q-1)$ already gives p and q). For a toy example take $p=5$, $q=11$, $n=55$, $(p-1)(q-1)=40$, $e=3$ and $d=27$, as $3\cdot 27 = 81 \equiv 1 \pmod{40}$: the message $m=2$ is encrypted as $c=8$, and $8^{27} \equiv 2 \pmod{55}$.

10.3 Orders and primitive roots

The powers of 2 modulo 11 are

$$2,\ 4,\ 8,\ 5,\ 10,\ 9,\ 7,\ 3,\ 6,\ 1,$$

so every nonzero residue modulo 11 is a power of 2, and U_{11} is a cyclic group generated by 2. The powers of any a modulo 8, on the other hand, are only 1 and a, since $1^2 = 3^2 - 8 = 5^2 - 24 = 7^2 - 48 = 1$; so U_8, of order 4, is not cyclic. This section determines all n for which U_n is cyclic.

Definition 10.3.1. Let $n \geq 1$ and $\gcd(a,n)=1$. The *order* of a modulo n, written $\mathrm{ord}_n(a)$, is the order of $\bar{a}$ in the group U_n: the least $k \geq 1$ with $a^k \equiv 1 \pmod{n}$. An integer g is a *primitive root* modulo n if $\mathrm{ord}_n(g) = \varphi(n)$, that is, if $\bar{g}$ generates U_n.

Lemma 10.3.2. *Let G be a group and $x \in G$ an element of finite order m.*

1. *$x^k = 1$ if and only if $m \mid k$.*
2. *For $k \geq 1$, the order of x^k is $m/\gcd(k,m)$.*
3. *If G is cyclic of order m generated by x, its generators are the x^k with $\gcd(k,m)=1$, and there are $\varphi(m)$ of them. For each $d \mid m$, G has exactly one subgroup of order d, generated by $x^{m/d}$, and the elements of G whose order divides d are exactly the elements of this subgroup.*

In particular $\mathrm{ord}_n(a)$ divides $\varphi(n)$, and $a^k \equiv 1 \pmod{n}$ if and only if $\mathrm{ord}_n(a) \mid k$.

Proof. (1) Write $k = qm + r$ with $0 \leq r < m$. Then $x^k = (x^m)^q x^r = x^r$ (Lemma 7.2.9), which is 1 exactly when $r=0$, by the minimality of m.

(2) Let $g = \gcd(k,m)$. By (1), $(x^k)^j = 1$ if and only if $m \mid kj$, that is, $\frac{m}{g} \mid \frac{k}{g} j$, that is, $\frac{m}{g} \mid j$, since $\gcd(\frac{k}{g}, \frac{m}{g}) = 1$ (as in the proof of Proposition 10.2.4). So the order of x^k is m/g.

(3) Every element is some x^k with $0 \leq k < m$, and by (2) it generates G, that is, has order m, if and only if $\gcd(k,m)=1$; the number of such k is $\varphi(m)$. Let $d \mid m$. An element x^k has order dividing d if and only if $x^{kd}=1$, that is, $m \mid kd$, that is, $\frac{m}{d} \mid k$; so these elements are the d powers of $x^{m/d}$, which form the subgroup generated by $x^{m/d}$, of order d by (2). Any subgroup H of order d consists of elements of order dividing d (Theorem 7.3.3), so H is contained in this subgroup and, having the same number of elements, equals it. The last assertion is (1) for $G = U_n$, with Lagrange's theorem. □

Theorem 10.3.3. *For every prime p the group $U_p = \mathbb{F}_p^\times$ is cyclic of order $p-1$: there is a primitive root modulo p, and there are exactly $\varphi(p-1)$ primitive roots among $1, \ldots, p-1$.*

Proof. $\mathbb{F}_p^\times$ is a finite subgroup of the multiplicative group of the field $\mathbb{F}_p$, so it is cyclic by Lemma 9.6.1. The number of generators is $\varphi(p-1)$ by Lemma 10.3.2(3). □

It is worth recalling why this is true, since the proof of Lemma 9.6.1 is short but indirect. The essential input is that a polynomial of degree d over a field has at most d roots (Corollary 8.6.7): so for each d there are at most d residues with $x^d \equiv 1 \pmod{p}$. In $\mathbb{Z}/8\mathbb{Z}$, which is not a field, the polynomial x^2-1 has the four roots $1,3,5,7$, and this is exactly why U_8 is not cyclic. Exercise 10.9.5 gives a second proof of the theorem by counting with Proposition 10.2.8(4).

Example 10.3.4. 1. By the list above, 2 is a primitive root modulo 11. There are $\varphi(10) = 4$ primitive roots, the powers 2^k with $\gcd(k, 10) = 1$: $2^1 = 2$, $2^3 = 8$, $2^7 \equiv 7$ and $2^9 \equiv 6$.

2. Modulo 7, the powers of 3 are $3, 2, 6, 4, 5, 1$, so 3 is a primitive root; the powers of 2 are $2, 4, 1$, so 2 is not.

3. To find a primitive root modulo p in practice, one tests $g = 2, 3, \ldots$: by Lemma 10.3.2, g is a primitive root if and only if $g^{(p-1)/\ell} \not\equiv 1 \pmod{p}$ for every prime $\ell \mid p-1$, since a proper divisor of $p-1$ divides some $(p-1)/\ell$. For $p = 23$, $p - 1 = 2 \cdot 11$; $2^{11} = 2048 = 89 \cdot 23 + 1$, so 2 is not a primitive root; $5^2 = 25 \equiv 2$ and $5^{11} = 5 \cdot (5^2)^5 \equiv 5 \cdot 2^5 = 160 \equiv -1 \pmod{23}$, so 5 is a primitive root modulo 23.

Remark 10.3.5. Whether 2 is a primitive root modulo infinitely many primes is not known. Artin conjectured in 1927 that every integer a that is neither -1 nor a perfect square is a primitive root modulo infinitely many primes; this is still open for every single value of a.

To pass from primes to prime powers we need a lemma on how powers of numbers close to 1 behave modulo powers of p.

Lemma 10.3.6. *Let p be a prime and $j \geq 1$, with $j \geq 2$ if $p = 2$. If $x \equiv 1 + p^j c \pmod{p^{j+1}}$ with $p \nmid c$, then $x^p \equiv 1 + p^{j+1}c \pmod{p^{j+2}}$. Consequently, under the same hypothesis, $x^{p^i} \equiv 1 + p^{j+i}c \pmod{p^{j+i+1}}$ for all $i \geq 0$.*

Proof. Write $x = 1 + p^j y$ with $y \equiv c \pmod{p}$. By the binomial theorem

$$x^p = 1 + p \cdot p^j y + \sum_{k=2}^{p} \binom{p}{k} p^{kj} y^k.$$

The second term is $p^{j+1}y \equiv p^{j+1}c \pmod{p^{j+2}}$. For $2 \leq k \leq p-1$, p divides $\binom{p}{k} = \frac{p!}{k!(p-k)!}$ (it divides the numerator and not the denominator, by Lemma 4.5.4), so the term is divisible by p^{1+kj}, and $1 + kj \geq 1 + 2j \geq j + 2$. The last term $p^{pj}y^p$ is divisible by p^{j+2} if $pj \geq j + 2$, that is, $(p-1)j \geq 2$, which holds if $p \geq 3$ or if $p = 2$ and $j \geq 2$. (For $p = 2$ there are no middle terms.) This proves the first statement; the second follows by induction on i, since x^{p^i} again satisfies the hypothesis, with $j + i$ in place of j. □

Theorem 10.3.7. *Let p be an odd prime and $k \geq 1$. Then U_{p^k} is cyclic. More precisely, if g is a primitive root modulo p with $g^{p-1} \not\equiv 1 \pmod{p^2}$, then g is a primitive root modulo p^k for every $k \geq 1$; and if g is any primitive root modulo p, then g or $g + p$ has this property.*

Proof. Let g be a primitive root modulo p. If $g^{p-1} \equiv 1 \pmod{p^2}$, then by the binomial theorem

$$(g+p)^{p-1} \equiv g^{p-1} + (p-1)g^{p-2}p \equiv 1 - pg^{p-2} \pmod{p^2},$$

which is $\not\equiv 1$ since $p \nmid g$; and $g + p \equiv g \pmod{p}$ is again a primitive root modulo p. So we may assume $g^{p-1} = 1 + pc$ with $p \nmid c$.

Let $d = \operatorname{ord}_{p^k}(g)$. Then $g^d \equiv 1 \pmod{p}$, so $p - 1 = \operatorname{ord}_p(g)$ divides d, and d divides $\varphi(p^k) = (p-1)p^{k-1}$ (Lemma 10.3.2, Proposition 10.2.8). Hence $d = (p-1)p^i$ for some $0 \leq i \leq k-1$. If $k \geq 2$ and $i \leq k-2$, then d divides $(p-1)p^{k-2}$, so $g^{(p-1)p^{k-2}} \equiv 1 \pmod{p^k}$; but Lemma 10.3.6 with $x = g^{p-1}$ and $j = 1$ gives $g^{(p-1)p^{k-2}} \equiv 1 + p^{k-1}c \pmod{p^k}$, which is $\not\equiv 1$. So $i = k-1$ and $d = \varphi(p^k)$. (For $k = 1$ there is nothing to prove.) □

Example 10.3.8. 3 is a primitive root modulo 7, and $3^6 = 729 = 14 \cdot 49 + 43 \not\equiv 1 \pmod{49}$. So 3 is a primitive root modulo 7^k for every k: for instance modulo 343 the powers of 3 run

through all $\varphi(343) = 294$ residues prime to 7. The exceptional case of the theorem does occur, but rarely: $p = 29$, $g = 14$ is a primitive root modulo 29 with $14^{28} \equiv 1 \pmod{29^2}$ (Exercise 10.9.6).

Powers of 2 behave differently, as U_8 already showed.

Theorem 10.3.9. *U_2 and U_4 are cyclic, of orders 1 and 2. For $k \geq 3$, $\operatorname{ord}_{2^k}(5) = 2^{k-2}$, and the map*

$$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2^{k-2}\mathbb{Z} \to U_{2^k}, \qquad (a, b) \mapsto (-1)^a 5^b,$$

is an isomorphism of groups. In particular U_{2^k} is not cyclic for $k \geq 3$.

Proof. $U_2 = \{\bar{1}\}$ and $U_4 = \{\bar{1}, \bar{3}\}$. Let $k \geq 3$. Since $5 = 1 + 2^2$, Lemma 10.3.6 with $p = 2$, $j = 2$, $c = 1$ gives $5^{2^i} \equiv 1 + 2^{i+2} \pmod{2^{i+3}}$. For $i = k - 3$ this says $5^{2^{k-3}} \equiv 1 + 2^{k-1} \not\equiv 1 \pmod{2^k}$; for $i = k - 2$ it gives $5^{2^{k-2}} \equiv 1 \pmod{2^k}$. So the order of 5 divides 2^{k-2} but not 2^{k-3}, and equals 2^{k-2}. The map of the statement is therefore a well defined homomorphism (both -1 and 5 have orders dividing 2 and 2^{k-2}, and U_{2^k} is abelian). It is injective: if $(-1)^a 5^b \equiv 1 \pmod{2^k}$, then reducing modulo 4, where $5 \equiv 1$, gives $(-1)^a \equiv 1 \pmod 4$, so a is even, and then $5^b \equiv 1$ gives $2^{k-2} \mid b$. Both groups have $2 \cdot 2^{k-2} = 2^{k-1} = \varphi(2^k)$ elements, so it is an isomorphism. Finally $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2^{k-2}\mathbb{Z}$ has the three elements $(1, 0)$, $(0, 2^{k-3})$, $(1, 2^{k-3})$ of order 2, while a cyclic group has at most one, by Lemma 10.3.2(3) with $d = 2$. □

Theorem 10.3.10 (Gauss)**.** *Let $n \geq 1$. There is a primitive root modulo n if and only if n is 1, 2, 4, p^k or $2p^k$, with p an odd prime and $k \geq 1$.*

Proof. For $n = 1, 2, 4$ and p^k this is Theorems 10.3.9 and 10.3.7, and $U_{2p^k} \cong U_2 \times U_{p^k} \cong U_{p^k}$ by Theorem 10.2.6, as U_2 is trivial. Conversely, a product $A \times B$ of two finite groups of even order is not cyclic: by Cauchy's theorem (Theorem 7.6.8) there are $x \in A$ and $y \in B$ of order 2, and then $(x, 1)$, $(1, y)$ and (x, y) are three elements of order 2, while a cyclic group has at most one. Now $\varphi(p^k) = p^{k-1}(p-1)$ is even for odd p, and $\varphi(2^k) = 2^{k-1}$ is even for $k \geq 2$.

Now let n be not of the listed forms. If n is a power of 2, then $n = 2^k$ with $k \geq 3$, and U_n is not cyclic by Theorem 10.3.9. Otherwise n has an odd prime factor p; write $n = p^k m$ with $k \geq 1$ and $p \nmid m$. Since n is neither p^k nor $2p^k$, we have $m \geq 3$. If m has an odd prime factor q, write $m = q^l m'$ with $q \nmid m'$; then $\varphi(m) = \varphi(q^l)\varphi(m')$ is even. If m has no odd prime factor, then $m = 2^a$ with $a \geq 2$, and $\varphi(m) = 2^{a-1}$ is even. In both cases $U_n \cong U_{p^k} \times U_m$ (Theorem 10.2.6) is a product of two groups of even order, hence not cyclic. □

A primitive root g modulo p turns multiplication into addition, as a logarithm does: every a prime to p is $a \equiv g^t$ for a unique t modulo $p - 1$, the *index* or *discrete logarithm* of a. This immediately answers the question of which residues are k-th powers.

Proposition 10.3.11. *Let p be a prime, $k \geq 1$, $d = \gcd(k, p-1)$, and $p \nmid a$. The congruence $x^k \equiv a \pmod p$ has a solution if and only if $a^{(p-1)/d} \equiv 1 \pmod p$, and then it has exactly d solutions modulo p. The k-th powers form a subgroup of U_p of index d.*

Proof. Fix a primitive root g (Theorem 10.3.3); then $t \mapsto g^t$ is an isomorphism $\mathbb{Z}/(p-1)\mathbb{Z} \to U_p$, under which $x \mapsto x^k$ becomes $s \mapsto ks$. Write $a = g^t$ and $x = g^s$. The congruence becomes $ks \equiv t \pmod{p-1}$, which by Proposition 10.2.4 is solvable if and only if $d \mid t$, and then has d solutions s modulo $p - 1$, that is, d solutions x modulo p. Finally $a^{(p-1)/d} = g^{t(p-1)/d} \equiv 1$ if and only if $p - 1 \mid t(p-1)/d$, that is, $d \mid t$. The k-th powers are the image of the homomorphism $x \mapsto x^k$, whose kernel has d elements (the solutions for $a = 1$), so the image has $(p-1)/d$ elements and index d. □

For instance, for $p \equiv 2 \pmod 3$ every residue is a cube modulo p (as $d = \gcd(3, p-1) = 1$), while for $p \equiv 1 \pmod 3$ exactly a third of the nonzero residues are cubes. The case $k = 2$, where $d = 2$ for every odd prime, is the subject of the next section.

10.4 Quadratic residues and quadratic reciprocity

Which numbers are squares modulo a prime p? Modulo $p = 2$ every number is a square, so let p be odd. The squares of $1, 2, \ldots, 10$ modulo 11 are $1, 4, 9, 5, 3, 3, 5, 9, 4, 1$: exactly half of the nonzero residues, $1, 3, 4, 5, 9$, are squares, each twice, as $x^2 = (-x)^2$. The question has a surprisingly deep answer, the law of quadratic reciprocity, which Euler conjectured and Gauss first proved in 1796.

Definition 10.4.1. Let p be an odd prime. An integer a with $p \nmid a$ is a *quadratic residue* modulo p if $x^2 \equiv a \pmod{p}$ has a solution, and a *quadratic nonresidue* otherwise. The *Legendre symbol* is

$$\left(\frac{a}{p}\right) = \begin{cases} 1 & \text{if } p \nmid a \text{ and } a \text{ is a quadratic residue modulo } p, \\ -1 & \text{if } a \text{ is a quadratic nonresidue modulo } p, \\ 0 & \text{if } p \mid a. \end{cases}$$

By definition $\left(\frac{a}{p}\right)$ depends only on a modulo p. The following criterion of Euler reduces its computation to a power, and shows that it is multiplicative in a.

Proposition 10.4.2 (Euler's criterion)**.** *Let p be an odd prime.*

1. *For every integer a, $\left(\frac{a}{p}\right) \equiv a^{(p-1)/2} \pmod{p}$.*
2. *There are exactly $\frac{p-1}{2}$ quadratic residues and $\frac{p-1}{2}$ quadratic nonresidues among $1, \ldots, p-1$.*
3. *$\left(\frac{ab}{p}\right) = \left(\frac{a}{p}\right)\left(\frac{b}{p}\right)$ for all integers a, b. So the product of two residues or of two nonresidues is a residue, and the product of a residue and a nonresidue is a nonresidue.*

Proof. (1) If $p \mid a$ both sides are $\equiv 0$. Otherwise let $y = a^{(p-1)/2}$. Then $y^2 = a^{p-1} \equiv 1$ by Fermat's theorem, so $y \equiv \pm 1$, because $y^2 - 1 = (y-1)(y+1)$ and $\mathbb{F}_p$ is a field. By Proposition 10.3.11 with $k = 2$ and $d = \gcd(2, p-1) = 2$, a is a quadratic residue if and only if $y \equiv 1$. So $y \equiv 1$ when $\left(\frac{a}{p}\right) = 1$ and $y \equiv -1$ when $\left(\frac{a}{p}\right) = -1$.

(2) The squares form a subgroup of index $d = 2$ of U_p, by Proposition 10.3.11.

(3) By (1), both sides are congruent to $(ab)^{(p-1)/2} = a^{(p-1)/2} b^{(p-1)/2}$ modulo p. Both sides lie in $\{-1, 0, 1\}$, and distinct elements of this set are not congruent modulo $p \geq 3$; so they are equal. □

By (3), to compute $\left(\frac{a}{p}\right)$ it suffices to factor a and know $\left(\frac{-1}{p}\right)$, $\left(\frac{2}{p}\right)$ and $\left(\frac{q}{p}\right)$ for odd primes q. The first is immediate.

Corollary 10.4.3. *For an odd prime p, $\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$: the congruence $x^2 \equiv -1 \pmod{p}$ is solvable if and only if $p \equiv 1 \pmod{4}$.*

Proof. By Euler's criterion $\left(\frac{-1}{p}\right) \equiv (-1)^{(p-1)/2} \pmod{p}$, and both sides are ± 1. The exponent $(p-1)/2$ is even exactly when $p \equiv 1 \pmod{4}$. □

For $p \equiv 1 \pmod{4}$ an explicit square root of -1 is $\left(\frac{p-1}{2}\right)!$ (Exercise 10.9.3); for instance modulo 13, $6! = 720 \equiv 5$ and $5^2 = 25 \equiv -1$. The corollary already has a pleasant consequence, an analogue of Euclid's theorem for a single residue class.

Proposition 10.4.4. *There are infinitely many primes $p \equiv 1 \pmod{4}$.*

Proof. Let $p_1, \ldots, p_k$ be primes and $N = (2p_1 \cdots p_k)^2 + 1$. Let q be a prime dividing N (Theorem 4.5.5). Then q is odd, as N is odd, and $x = 2p_1 \cdots p_k$ satisfies $x^2 \equiv -1 \pmod{q}$; by Corollary 10.4.3, $q \equiv 1 \pmod{4}$. And $q \neq p_i$, since $p_i \mid N - 1$. So no finite list contains all primes $\equiv 1 \pmod{4}$. □

More generally, Dirichlet's theorem says that every residue class $a \bmod n$ with $\gcd(a,n) = 1$ contains infinitely many primes; its proof requires analysis [Ser73]. For the class of 3 modulo 4 see Exercise 10.9.1.

To compute $(\frac{2}{p})$ and $(\frac{q}{p})$ we use a lemma of Gauss, which counts signs in the proof of Euler's criterion.

Lemma 10.4.5 (Gauss's lemma)**.** *Let p be an odd prime, $h = \frac{p-1}{2}$, and $p \nmid a$. Let μ be the number of $k \in \{1, \dots, h\}$ for which the least non-negative residue of ka modulo p is greater than $\frac{p}{2}$. Then $\left(\frac{a}{p}\right) = (-1)^{\mu}$.*

Proof. For $1 \le k \le h$, let t_k be the least non-negative residue of ka; it is not 0, as $p \nmid ka$. Put $r_k = t_k$ and $\varepsilon_k = 1$ if $t_k < p/2$, and $r_k = p - t_k$ and $\varepsilon_k = -1$ if $t_k > p/2$. Then $ka \equiv \varepsilon_k r_k \pmod p$ with $r_k \in \{1, \dots, h\}$, and exactly μ of the signs ε_k are -1. The r_k are distinct: if $r_k = r_l$, then $ka \equiv \pm la$, so $k \equiv \pm l \pmod p$ (cancel the unit a); since $1 \le k, l \le h$ we have $0 < k + l < p$ and $|k - l| < p$, so $k \equiv -l$ is impossible and $k = l$. Hence $\{r_1, \dots, r_h\} = \{1, \dots, h\}$, and multiplying the congruences $ka \equiv \varepsilon_k r_k$ for $k = 1, \dots, h$ gives

$$a^h\, h! \equiv (-1)^{\mu}\, h! \pmod p.$$

Since $h!$ is prime to p, $a^h \equiv (-1)^{\mu}$, and Euler's criterion gives $(\frac{a}{p}) \equiv (-1)^{\mu}$; both sides are ± 1, so they are equal. □

Example 10.4.6. For $p = 11$, $h = 5$ and $a = 3$: the residues of $3, 6, 9, 12, 15$ are $3, 6, 9, 1, 4$, of which 6 and 9 exceed 5.5. So $\mu = 2$ and $(\frac{3}{11}) = 1$; indeed $5^2 = 25 \equiv 3$. For $a = 2$: the residues $2, 4, 6, 8, 10$ include $6, 8, 10$ above 5.5, so $\mu = 3$ and $(\frac{2}{11}) = -1$, in agreement with the list of squares modulo 11 above.

Proposition 10.4.7 (The second supplementary law)**.** *For an odd prime p, $\left(\frac{2}{p}\right) = (-1)^{(p^2-1)/8}$: the number 2 is a quadratic residue modulo p if and only if $p \equiv \pm 1 \pmod 8$.*

Proof. For $a = 2$ the numbers $2k$, $1 \le k \le h$, already lie in $\{1, \dots, p-1\}$, and $2k > p/2$ exactly when $k > p/4$. So $\mu = h - \lfloor p/4 \rfloor$. Writing $p = 8m + r$ with $r \in \{1, 3, 5, 7\}$:

$$r = 1: \quad h = 4m,\ \lfloor p/4 \rfloor = 2m,\ \mu = 2m; \qquad r = 3: \quad h = 4m+1,\ \lfloor p/4 \rfloor = 2m,\ \mu = 2m+1;$$
$$r = 5: \quad h = 4m+2,\ \lfloor p/4 \rfloor = 2m+1,\ \mu = 2m+1; \qquad r = 7: \quad h = 4m+3,\ \lfloor p/4 \rfloor = 2m+1,\ \mu = 2m+2.$$

So μ is even exactly for $p \equiv \pm 1 \pmod 8$, and Gauss's lemma gives the first assertion in the form "$(\frac{2}{p}) = 1$ if and only if $p \equiv \pm 1 \pmod 8$". Finally $(p^2-1)/8$ is even for $p = 8m \pm 1$, where it equals $8m^2 \pm 2m$, and odd for $p = 8m \pm 3$, where it equals $8m^2 \pm 6m + 1$. □

For odd a the count μ in Gauss's lemma can be expressed through integer parts, which is the key to the reciprocity law.

Lemma 10.4.8 (Eisenstein)**.** *Let p be an odd prime, $h = \frac{p-1}{2}$, and a an odd integer with $p \nmid a$. Then, with μ as in Gauss's lemma,*

$$\mu \equiv \sum_{k=1}^{h} \left\lfloor \frac{ka}{p} \right\rfloor \pmod 2, \qquad \text{so} \qquad \left(\frac{a}{p}\right) = (-1)^{\sum_{k=1}^{h} \lfloor ka/p \rfloor}.$$

Proof. Divide: $ka = p\lfloor ka/p \rfloor + t_k$ with t_k the least non-negative residue. Let $b_1, \dots, b_\mu$ be the t_k greater than $p/2$ and $c_1, \dots, c_\lambda$ the others ($\lambda + \mu = h$). In the proof of Gauss's lemma we

saw that the numbers $c_1, \dots, c_\lambda, p - b_1, \dots, p - b_\mu$ are $1, \dots, h$ in some order. Summing the divisions and this rearrangement,

$$a \sum_{k=1}^{h} k = p \sum_{k=1}^{h} \left\lfloor \frac{ka}{p} \right\rfloor + \sum_i b_i + \sum_i c_i, \qquad \sum_{k=1}^{h} k = \sum_i c_i + \mu p - \sum_i b_i.$$

Subtracting, $(a-1)\sum_k k = p\sum_k \lfloor ka/p \rfloor - \mu p + 2\sum_i b_i$. Modulo 2, the left side is 0 because a is odd, and $p \equiv 1$; so $0 \equiv \sum_k \lfloor ka/p \rfloor - \mu$. The formula for the symbol is Gauss's lemma. □

Theorem 10.4.9 (Law of quadratic reciprocity)**.** *Let $p \neq q$ be odd primes. Then*

$$\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\cdot\frac{q-1}{2}}.$$

That is, $(\frac{p}{q}) = (\frac{q}{p})$ unless $p \equiv q \equiv 3 \pmod 4$, in which case $(\frac{p}{q}) = -(\frac{q}{p})$.

Proof. Let $h = \frac{p-1}{2}$ and $h' = \frac{q-1}{2}$, and count the points with integer coordinates in the rectangle $R = \{(x, y) : 1 \le x \le h,\ 1 \le y \le h'\}$; there are hh' of them. None lies on the line $py = qx$: if $py = qx$ with $1 \le x \le h$, then $p \mid qx$, so $p \mid x$ by Euclid's lemma, which is impossible for $0 < x < p$.

The points of R with $py < qx$, that is, below the line: for fixed $x \in \{1, \dots, h\}$ these are the y with $1 \le y < qx/p$, and all such y satisfy $y \le h'$, since $qx/p < q/2$ and so $y < q/2$, that is $y \le (q-1)/2$. Their number is $\lfloor qx/p \rfloor$ (as qx/p is not an integer). So there are $\sum_{x=1}^{h} \lfloor qx/p \rfloor$ points below the line, and symmetrically $\sum_{y=1}^{h'} \lfloor py/q \rfloor$ points above it. Hence

$$\sum_{x=1}^{h} \left\lfloor \frac{qx}{p} \right\rfloor + \sum_{y=1}^{h'} \left\lfloor \frac{py}{q} \right\rfloor = hh'.$$

By Eisenstein's lemma (Lemma 10.4.8), applied to the odd number q modulo p and to p modulo q, the left side is the sum of the exponents in $(\frac{q}{p}) = (-1)^{\sum \lfloor qx/p \rfloor}$ and $(\frac{p}{q}) = (-1)^{\sum \lfloor py/q \rfloor}$. So $(\frac{p}{q})(\frac{q}{p}) = (-1)^{hh'}$. Finally hh' is odd if and only if both h and h' are odd, that is, $p \equiv q \equiv 3 \pmod 4$. □

To see the proof at work, take $p = 11$ and $q = 7$, so $h = 5$ and $h' = 3$. The rectangle contains the 15 points (x, y) with $1 \le x \le 5$ and $1 \le y \le 3$. Below the line $11y = 7x$ lie, for $x = 1, \dots, 5$, respectively $\lfloor 7/11 \rfloor, \lfloor 14/11 \rfloor, \dots = 0, 1, 1, 2, 3$ points, 7 in all; to the left of it lie, for $y = 1, 2, 3$, respectively $\lfloor 11/7 \rfloor, \lfloor 22/7 \rfloor, \lfloor 33/7 \rfloor = 1, 3, 4$ points, 8 in all. So $(\frac{7}{11}) = (-1)^7 = -1$ and $(\frac{11}{7}) = (-1)^8 = 1$, and their product is $-1 = (-1)^{15}$. Directly: $(\frac{11}{7}) = (\frac{4}{7}) = 1$, and the squares modulo 11 are $1, 3, 4, 5, 9$, which do not include 7.

Together with Euler's criterion and the two supplementary laws, Corollary 10.4.3 and Proposition 10.4.7, reciprocity computes every Legendre symbol quickly, by repeatedly reducing the top modulo the bottom, factoring, and flipping.

Example 10.4.10.

1. *Is 30 a square modulo the prime 103?* $(\frac{30}{103}) = (\frac{2}{103})(\frac{3}{103})(\frac{5}{103})$. As $103 \equiv 7 \pmod 8$, $(\frac{2}{103}) = 1$. As $103 \equiv 3 \pmod 4$ and $3 \equiv 3 \pmod 4$, $(\frac{3}{103}) = -(\frac{103}{3}) = -(\frac{1}{3}) = -1$. As $5 \equiv 1 \pmod 4$, $(\frac{5}{103}) = (\frac{103}{5}) = (\frac{3}{5}) = -1$, the squares modulo 5 being 1 and 4. So $(\frac{30}{103}) = 1 \cdot (-1) \cdot (-1) = 1$: 30 is a square modulo 103. Indeed $37^2 = 1369 = 13 \cdot 103 + 30$. Note that reciprocity decides the question without finding the square root.

2. *For which primes is 3 a square?* For $p > 3$, $(\frac{3}{p}) = (-1)^{(p-1)/2}(\frac{p}{3})$, and $(\frac{p}{3}) = 1$ if and only if $p \equiv 1 \pmod 3$. So $(\frac{3}{p}) = 1$ if and only if $p \equiv 1 \pmod 4$ and $p \equiv 1 \pmod 3$, or $p \equiv 3 \pmod 4$ and $p \equiv 2 \pmod 3$; that is, by the Chinese remainder theorem, if and only if $p \equiv \pm 1 \pmod{12}$.

3. *For which primes is* 5 *a square?* For $p \neq 2, 5$, $(\frac{5}{p}) = (\frac{p}{5})$, which is 1 if and only if $p \equiv \pm 1 \pmod 5$. This is the remarkable feature of the law: whether q is a square modulo p depends only on p modulo $4q$, although the squares modulo p seem to have nothing to do with q.

Remark 10.4.11. Gauss called the law the *theorema aureum* and gave several proofs of it; the one above, by counting lattice points, is due to Eisenstein. Another proof uses Gauss sums: the sum $g = \sum_{a=1}^{q-1} (\frac{a}{q}) \zeta^a$, with ζ a primitive q-th root of unity, satisfies $g^2 = (-1)^{(q-1)/2} q$, so the cyclotomic field $\mathbb{Q}(\zeta)$ of Theorem 9.8.2 contains a square root of $\pm q$, and comparing g^p with g modulo p gives the law [IR90]. This is the beginning of a Galois theoretic explanation, in which $(\frac{p}{q})$ describes how the automorphism $\zeta \mapsto \zeta^p$ acts on that square root; its generalisation to all abelian extensions of number fields is class field theory.

10.5 Sums of squares

Which integers are sums of two squares? The first few are

$$0, 1, 2, 4, 5, 8, 9, 10, 13, 16, 17, 18, 20, 25, 26, 29, \ldots,$$

and among the odd primes, $5, 13, 17, 29, 37, 41$ appear, while $3, 7, 11, 19, 23, 31$ do not. By Example 10.2.2(2), no number $\equiv 3 \pmod 4$ is a sum of two squares. Fermat stated in 1640 that every prime $p \equiv 1 \pmod 4$ is one; Euler gave the first proof. We give a proof through the Gaussian integers, in which a sum of two squares factors: $a^2 + b^2 = (a + bi)(a - bi)$.

Recall from Example 8.5.5 that $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$ is a Euclidean domain for the norm $N(a + bi) = a^2 + b^2 = |a + bi|^2$, hence a PID and a UFD (Theorem 8.5.4). The norm is multiplicative, $N(zw) = |zw|^2 = N(z)N(w)$. Its units are the elements of norm 1, namely ± 1 and $\pm i$: if $zw = 1$ then $N(z)N(w) = 1$ in $\mathbb{N}$, so $N(z) = 1$; conversely $N(z) = z\bar{z} = 1$ gives $z^{-1} = \bar{z} \in \mathbb{Z}[i]$.

Theorem 10.5.1 (Fermat)**.** *An odd prime p is a sum of two squares if and only if $p \equiv 1 \pmod 4$. In that case the representation $p = a^2 + b^2$ is unique up to order and signs of a and b.*

Proof. If $p = a^2 + b^2$ then $p \not\equiv 3 \pmod 4$ by Example 10.2.2(2), so $p \equiv 1 \pmod 4$. Conversely let $p \equiv 1 \pmod 4$. By Corollary 10.4.3 there is $x \in \mathbb{Z}$ with $p \mid x^2 + 1 = (x + i)(x - i)$. But p divides neither factor in $\mathbb{Z}[i]$, since $(x \pm i)/p = x/p \pm i/p$ does not have integer coefficients. So p is not a prime element of $\mathbb{Z}[i]$, and since $\mathbb{Z}[i]$ is a UFD, p is not irreducible (Lemma 8.5.3): $p = zw$ with z, w not units. Then $p^2 = N(p) = N(z)N(w)$ with $N(z), N(w) > 1$, so $N(z) = p$, and writing $z = a + bi$, $p = a^2 + b^2$.

For uniqueness, let $p = a^2 + b^2 = c^2 + d^2$. Then $z = a + bi$ is irreducible: if $z = uv$, then $p = N(u)N(v)$, so one of $N(u)$, $N(v)$ is 1. In a UFD irreducible elements are prime, and z divides $p = (c + di)(c - di)$, so z divides $c + di$ or $c - di$; as both have norm $p = N(z)$, the quotient has norm 1 and is a unit. So $c + di$ or $c - di$ is $\pm(a + bi)$ or $\pm i(a + bi) = \mp(b - ai)$, and (c, d) is (a, b) or (b, a) up to order and signs. □

Example 10.5.2. $5 = 1^2 + 2^2$, $13 = 2^2 + 3^2$, $17 = 1^2 + 4^2$, $29 = 2^2 + 5^2$, $37 = 1^2 + 6^2$, $41 = 4^2 + 5^2$, and $1013 = 22^2 + 23^2$. The proof can be made into an algorithm: find x with $x^2 \equiv -1 \pmod p$, and compute a greatest common divisor of p and $x + i$ in $\mathbb{Z}[i]$ with the Euclidean algorithm. For $p = 13$, $x = 5$: dividing 13 by $5 + i$ gives $13/(5 + i) = 13(5 - i)/26 = (5 - i)/2$, rounded to $q = 2$ (or $3 - i$), with remainder $13 - 2(5 + i) = 3 - 2i$; and $(5 + i)/(3 - 2i) = (5 + i)(3 + 2i)/13 = (13 + 13i)/13 = 1 + i$ exactly. So the gcd is $3 - 2i$, and $13 = 3^2 + 2^2$.

Products of sums of two squares are sums of two squares, by the multiplicativity of the norm: writing out $N(zw) = N(z)N(w)$ for $z = a + bi$, $w = c + di$ gives the identity of Brahmagupta and Fibonacci,

$$(a^2 + b^2)(c^2 + d^2) = (ac - bd)^2 + (ad + bc)^2. \tag{10.1}$$

Theorem 10.5.3. *An integer $n \geq 1$ is a sum of two squares if and only if every prime $q \equiv 3 \pmod 4$ occurs in the prime factorisation of n with an even exponent.*

Proof. Suppose the condition holds. Then n is a product of factors $2 = 1^2 + 1^2$, primes $p \equiv 1 \pmod 4$, which are sums of two squares by Theorem 10.5.1, and squares $q^2 = q^2 + 0^2$; by (10.1) and induction on the number of factors, so is n.

Conversely let $n = a^2 + b^2$ and let $q \equiv 3 \pmod 4$ be a prime dividing n. We claim that $q \mid a$ and $q \mid b$. If $q \nmid b$, let b' be an inverse of b modulo q; then $a^2 \equiv -b^2$ gives $(ab')^2 \equiv -1 \pmod q$, contradicting Corollary 10.4.3. So $q \mid b$, hence $q \mid a^2$ and $q \mid a$. Then $q^2 \mid n$ and $n/q^2 = (a/q)^2 + (b/q)^2$ is again a sum of two squares. By induction on n, the exponent of q in n/q^2 is even, hence so is its exponent in n. □

Example 10.5.4. $2026 = 2 \cdot 1013$ with $1013 \equiv 1 \pmod 4$ prime, so 2026 is a sum of two squares; by (10.1) with $2 = 1^2 + 1^2$ and $1013 = 22^2 + 23^2$, $2026 = (22 - 23)^2 + (23 + 22)^2 = 1^2 + 45^2$. The number $65 = 5 \cdot 13$ has the two essentially different representations $1^2 + 8^2$ and $4^2 + 7^2$, coming from $(1 + 2i)(2 + 3i) = -4 + 7i$ and $(1 + 2i)(2 - 3i) = 8 + i$. On the other hand $21 = 3 \cdot 7$ and $2027 \equiv 3 \pmod 4$ are not sums of two squares, while $9 \cdot 7^2 = 441 = 21^2 + 0^2$ is.

Not every positive integer is a sum of three squares: no number $\equiv 7 \pmod 8$ is, since squares are $\equiv 0, 1, 4 \pmod 8$ and no three of these add up to 7. (Legendre and Gauss proved that the numbers that are not sums of three squares are exactly those of the form $4^a(8b + 7)$; we do not prove this, see [Ser73].) Four squares always suffice. The proof follows the same pattern as for two squares, with an identity of Euler in place of (10.1), and Fermat's method of descent in place of the Gaussian integers.

Lemma 10.5.5 (Euler's four-square identity)**.** *For all $a_1, \dots, a_4, b_1, \dots, b_4$ in a commutative ring,*

$$\Big(\sum_{i=1}^{4} a_i^2\Big)\Big(\sum_{i=1}^{4} b_i^2\Big) = z_1^2 + z_2^2 + z_3^2 + z_4^2,$$

where

$$z_1 = a_1b_1 + a_2b_2 + a_3b_3 + a_4b_4, \quad z_2 = a_1b_2 - a_2b_1 + a_3b_4 - a_4b_3,$$
$$z_3 = a_1b_3 - a_3b_1 + a_4b_2 - a_2b_4, \quad z_4 = a_1b_4 - a_4b_1 + a_2b_3 - a_3b_2.$$

Proof. Expand. Each z_k^2 contains four squares $a_i^2 b_j^2$, and the sixteen squares that occur are all the $a_i^2 b_j^2$, each once: z_1 contains the products a_ib_i, and z_2, z_3, z_4 contain the products a_ib_j for the pairs $\{i, j\}$ equal to $\{1, 2\}$ and $\{3, 4\}$, to $\{1, 3\}$ and $\{2, 4\}$, and to $\{1, 4\}$ and $\{2, 3\}$ respectively. The cross terms cancel in pairs; for instance the terms containing a_1a_2 are $2a_1a_2b_1b_2$ from z_1^2, $-2a_1a_2b_2b_1$ from z_2^2, $-2a_1a_2b_3b_4$ from z_3^2 and $2a_1a_2b_4b_3$ from z_4^2, with sum 0; the other five pairs a_ia_j are handled in the same way. (The identity expresses the multiplicativity of the norm of quaternions, $|xy|^2 = |x|^2|y|^2$.) □

Theorem 10.5.6 (Lagrange)**.** *Every positive integer is a sum of four squares of integers.*

Proof. By Lemma 10.5.5 and the factorisation into primes, and since $1 = 1^2 + 0^2 + 0^2 + 0^2$ and $2 = 1^2 + 1^2 + 0^2 + 0^2$, it suffices to treat an odd prime p.

Step 1: some multiple mp with $1 \le m < p$ is a sum of four squares. The $\frac{p+1}{2}$ numbers x^2, $0 \le x \le \frac{p-1}{2}$, are pairwise incongruent modulo p: if $x^2 \equiv x'^2$, then $p \mid (x-x')(x+x')$, and $0 \le x + x' < p$, $|x - x'| < p$, so $x = x'$. Likewise the $\frac{p+1}{2}$ numbers $-1 - y^2$, $0 \le y \le \frac{p-1}{2}$, are pairwise incongruent. Since $\frac{p+1}{2} + \frac{p+1}{2} > p$, some x^2 is congruent to some $-1 - y^2$, so $x^2 + y^2 + 1^2 + 0^2 = mp$ for some $m \ge 1$, and $mp \le 2\left(\frac{p-1}{2}\right)^2 + 1 < p^2$, so $m < p$.

Step 2: descent. Let m be the least positive integer such that mp is a sum of four squares; by Step 1, $m < p$. Suppose $m > 1$, and write $mp = x_1^2 + x_2^2 + x_3^2 + x_4^2$.

If m is even, then $\sum x_i^2$ is even, so an even number of the x_i are odd, and we may number them so that $x_1 \equiv x_2$ and $x_3 \equiv x_4 \pmod 2$. Then

$$\frac{m}{2}p = \left(\frac{x_1+x_2}{2}\right)^2 + \left(\frac{x_1-x_2}{2}\right)^2 + \left(\frac{x_3+x_4}{2}\right)^2 + \left(\frac{x_3-x_4}{2}\right)^2,$$

a sum of four squares of integers, contradicting the minimality of m.

If m is odd, $m \ge 3$, choose $y_i \equiv x_i \pmod m$ with $|y_i| < m/2$ (possible since m is odd). Then $\sum y_i^2 \equiv \sum x_i^2 = mp \equiv 0 \pmod m$, so $\sum y_i^2 = mr$ with $0 \le r$, and $mr < 4(m/2)^2 = m^2$, so $r < m$. If $r = 0$, all $y_i = 0$, so m divides every x_i, $m^2 \mid mp$ and $m \mid p$, impossible for $1 < m < p$. So $1 \le r < m$. By Lemma 10.5.5,

$$m^2 rp = \left(\sum x_i^2\right)\left(\sum y_i^2\right) = z_1^2 + z_2^2 + z_3^2 + z_4^2,$$

with the z_k formed from $a_i = x_i$, $b_i = y_i$. Since $y_i \equiv x_i \pmod m$, $z_1 \equiv \sum x_i^2 \equiv 0$, and $z_2 \equiv x_1x_2 - x_2x_1 + x_3x_4 - x_4x_3 = 0 \pmod m$, and likewise $z_3 \equiv z_4 \equiv 0$. So $rp = \sum (z_k/m)^2$ is a sum of four squares of integers with $1 \le r < m$, again contradicting the minimality of m. Hence $m = 1$. □

Example 10.5.7. $7 = 2^2 + 1^2 + 1^2 + 1^2$ needs four squares, as $7 \equiv 7 \pmod 8$. Also $2026 = 45^2 + 1^2 + 0^2 + 0^2$, $15 = 3^2 + 2^2 + 1^2 + 1^2$ and $2027 = 45^2 + 1^2 + 1^2 + 0^2$.

10.6 Arithmetic functions and Möbius inversion

Euler's function is one of many functions on the positive integers that are determined by their values on prime powers. This section develops the algebra of such functions.

Definition 10.6.1. An *arithmetic function* is a function $f : \{1, 2, 3, \ldots\} \to \mathbb{C}$. It is *multiplicative* if $f(1) = 1$ and $f(mn) = f(m)f(n)$ whenever $\gcd(m, n) = 1$, and *completely multiplicative* if moreover $f(mn) = f(m)f(n)$ for all m, n. The *Dirichlet convolution* of arithmetic functions f and g is

$$(f * g)(n) = \sum_{d \mid n} f(d)\, g\left(\frac{n}{d}\right) = \sum_{de = n} f(d)\, g(e),$$

the sums running over the positive divisors d of n, that is, over the pairs of positive integers (d, e) with $de = n$.

A multiplicative function is determined by its values at prime powers: $f(p_1^{k_1} \cdots p_r^{k_r}) = f(p_1^{k_1}) \cdots f(p_r^{k_r})$. We use the following functions:

- $\varepsilon(1) = 1$ and $\varepsilon(n) = 0$ for $n > 1$; $\mathbf{1}(n) = 1$ for all n; $\mathrm{N}(n) = n$. These are completely multiplicative.
- Euler's function φ, multiplicative by Proposition 10.2.8.

- $\tau(n)$, the number of positive divisors of n, and $\sigma(n)$, their sum. By definition $\tau = \mathbf{1} * \mathbf{1}$ and $\sigma = \mathrm{N} * \mathbf{1}$.
- The *Möbius function*: $\mu(1) = 1$, $\mu(n) = (-1)^r$ if n is a product of r distinct primes, and $\mu(n) = 0$ if n is divisible by the square of a prime. It is multiplicative but not completely multiplicative: $\mu(4) = 0 \neq \mu(2)^2$.

In this notation Proposition 10.2.8(4) reads $\varphi * \mathbf{1} = \mathrm{N}$.

Proposition 10.6.2. *1. Dirichlet convolution is commutative and associative, and ε is its identity element. With pointwise addition, the arithmetic functions form a commutative ring.*

2. An arithmetic function f has an inverse for $*$ if and only if $f(1) \neq 0$.

3. If f and g are multiplicative, so is $f * g$; and the inverse of a multiplicative function is multiplicative.

Proof. (1) Commutativity holds because $(f*g)(n) = \sum_{de=n} f(d)g(e)$ is symmetric in the roles of d and e. Associativity: both $((f*g)*h)(n)$ and $(f*(g*h))(n)$ equal $\sum_{cde=n} f(c)g(d)h(e)$, the sum over the triples of positive integers with product n. Further $(\varepsilon * f)(n) = \sum_{de=n} \varepsilon(d)f(e) = f(n)$. Distributivity over addition is clear.

(2) If $f * g = \varepsilon$, then $f(1)g(1) = 1$. Conversely, if $f(1) \neq 0$, define g recursively by $g(1) = 1/f(1)$ and, for $n > 1$,

$$g(n) = -\frac{1}{f(1)} \sum_{d \mid n,\ d>1} f(d)\, g\Big(\frac{n}{d}\Big),$$

which only involves values of g at numbers less than n. This says exactly that $(f * g)(1) = 1$ and $(f * g)(n) = 0$ for $n > 1$.

(3) Let $\gcd(m, n) = 1$. By unique factorisation, every divisor d of mn is uniquely a product $d = d_1 d_2$ with $d_1 \mid m$ and $d_2 \mid n$ (namely $d_1 = \gcd(d, m)$, $d_2 = \gcd(d, n)$), and then $\gcd(d_1, d_2) = \gcd(m/d_1, n/d_2) = 1$. Hence

$$(f * g)(mn) = \sum_{d_1 \mid m,\ d_2 \mid n} f(d_1) f(d_2)\, g\Big(\frac{m}{d_1}\Big) g\Big(\frac{n}{d_2}\Big) = (f * g)(m)\,(f * g)(n),$$

and $(f * g)(1) = 1$. For the inverse, let f be multiplicative, g its inverse, and let h be the multiplicative function with $h(p^k) = g(p^k)$ for all prime powers. Then $f * h$ is multiplicative by what we just proved, and $(f * h)(p^k) = \sum_{j=0}^{k} f(p^j)g(p^{k-j}) = (f * g)(p^k) = \varepsilon(p^k)$, because the divisors of p^k are the p^j. So $f * h$ and ε are multiplicative functions that agree on prime powers, hence $f * h = \varepsilon$ and $h = g$ by uniqueness of inverses. □

Proposition 10.6.3. *$\mu * \mathbf{1} = \varepsilon$; that is, $\sum_{d \mid n} \mu(d) = 0$ for every $n > 1$.*

Proof. Both sides are multiplicative (Proposition 10.6.2(3)), so it suffices to compare them at $n = p^k$, $k \geq 1$: the divisors are $1, p, \ldots, p^k$, and $\sum_{j=0}^{k} \mu(p^j) = 1 - 1 + 0 + \cdots + 0 = 0 = \varepsilon(p^k)$. □

Theorem 10.6.4 (Möbius inversion)**.** *For arithmetic functions f and g,*

$$g(n) = \sum_{d \mid n} f(d) \text{ for all } n \qquad \text{if and only if} \qquad f(n) = \sum_{d \mid n} \mu(d)\, g\Big(\frac{n}{d}\Big) \text{ for all } n.$$

Proof. The left side says $g = f * \mathbf{1}$, the right side $f = g * \mu$. Since μ is the inverse of $\mathbf{1}$ (Proposition 10.6.3), multiplying $g = f * \mathbf{1}$ by μ gives $g * \mu = f$, and multiplying $f = g * \mu$ by $\mathbf{1}$ gives $f * \mathbf{1} = g$. □

Example 10.6.5. 1. From $\varphi * \mathbf{1} = \mathrm{N}$, inversion gives $\varphi(n) = \sum_{d|n} \mu(d)\frac{n}{d} = n\sum_{d|n}\frac{\mu(d)}{d}$. Only squarefree d contribute, and for $n = p_1^{k_1}\cdots p_r^{k_r}$ the sum is $\prod_i(1-1/p_i)$, recovering Proposition 10.2.8(3).

2. τ and σ are multiplicative, being convolutions of multiplicative functions, and $\tau(p^k) = k+1$, $\sigma(p^k) = 1+p+\cdots+p^k = \frac{p^{k+1}-1}{p-1}$. So $\tau(n) = \prod_i(k_i+1)$ and $\sigma(n) = \prod_i \frac{p_i^{k_i+1}-1}{p_i-1}$. For instance $\tau(12) = 3\cdot 2 = 6$ and $\sigma(12) = 7\cdot 4 = 28 = 1+2+3+4+6+12$.

3. *Counting irreducible polynomials.* Let I_d be the number of monic irreducible polynomials of degree d over $\mathbb{F}_p$. We claim that $p^n = \sum_{d|n} dI_d$. By Theorem 9.6.2(2), $\mathbb{F}_{p^n}$ consists of the p^n roots of $x^{p^n} - x$, which are distinct. Each $\alpha \in \mathbb{F}_{p^n}$ has a minimal polynomial over $\mathbb{F}_p$ (Proposition 9.2.4), monic irreducible of some degree $d = [\mathbb{F}_p(\alpha) : \mathbb{F}_p]$, which divides n by the tower law (Theorem 9.2.2). Conversely, a monic irreducible f of degree $d \mid n$ has a root β in a field $\mathbb{F}_p(\beta) = \mathbb{F}_p[x]/(f)$ with p^d elements, so $\beta^{p^d} = \beta$ by Theorem 9.6.2(2), hence $\beta^{p^n} = \beta$ (apply $x \mapsto x^{p^d}$ n/d times), and f, being the minimal polynomial of β, divides $x^{p^n} - x$. As $x^{p^n} - x$ is the product of the $x - \alpha$ over the p^n distinct $\alpha \in \mathbb{F}_{p^n}$, f has exactly d distinct roots in $\mathbb{F}_{p^n}$, and these are exactly the elements with minimal polynomial f. Counting the elements of $\mathbb{F}_{p^n}$ according to their minimal polynomials gives the claim. Möbius inversion, applied to $g(n) = p^n$ and $f(d) = dI_d$, gives $nI_n = \sum_{d|n}\mu(d)p^{n/d}$. For $n = 2$: $I_2 = (p^2-p)/2$; for $p = 2$, $n = 4$: $I_4 = (16-4)/4 = 3$, namely x^4+x+1, x^4+x^3+1 and $x^4+x^3+x^2+x+1$. In particular $I_n > 0$ for all n: the term $d = 1$ of the sum is p^n, and the others have absolute value at most $p^{n/d} \le p^{n/2}$, so $nI_n \ge p^n - \sum_{e=0}^{\lfloor n/2\rfloor} p^e > p^n - p^{\lfloor n/2\rfloor+1} \ge 0$ for $n \ge 2$.

A number n is *perfect* if it is the sum of its divisors smaller than itself, that is, if $\sigma(n) = 2n$: for instance $6 = 1+2+3$, $28 = 1+2+4+7+14$, 496 and 8128. Euclid observed that $2^{k-1}(2^k-1)$ is perfect when $2^k - 1$ is prime; Euler proved the converse for even numbers.

Theorem 10.6.6 (Euclid, Euler)**.** *An even number n is perfect if and only if $n = 2^{k-1}(2^k-1)$ with $k \ge 2$ and $2^k - 1$ prime.*

Proof. If $q = 2^k - 1$ is prime, then by multiplicativity $\sigma(2^{k-1}q) = \sigma(2^{k-1})\sigma(q) = (2^k-1)(q+1) = (2^k-1)2^k = 2n$.

Conversely let n be even and perfect, and write $n = 2^{k-1}m$ with $k \ge 2$ and m odd. Then

$$2^k m = 2n = \sigma(n) = \sigma(2^{k-1})\sigma(m) = (2^k-1)\sigma(m).$$

Since $2^k - 1$ is odd, it is coprime to 2^k, so it divides m: $m = (2^k-1)M$, and then $\sigma(m) = 2^k M = m + M$. Now m and M are distinct divisors of m, as $2^k - 1 \ge 3$, and $\sigma(m) = m + M$ says that they are the only divisors of m. As 1 divides m, $M = 1$, and $m = 2^k - 1$ has only the divisors 1 and m: it is prime. □

Remark 10.6.7. Primes of the form $2^k - 1$ are called *Mersenne primes*; k must then be prime (Exercise 10.9.10), but this is not sufficient: $2^{11} - 1 = 2047 = 23\cdot 89$. It is unknown whether there are infinitely many Mersenne primes, and whether any odd perfect number exists.

10.7 Gaussian and Eisenstein integers

In Section 10.5 the Gaussian integers were a tool for proving Fermat's theorem on sums of two squares. Here we study the ring $\mathbb{Z}[i]$ for its own sake: we determine all its primes, which describes how each rational prime factors there, and we use the factorisation to count the

representations of an integer as a sum of two squares. The same method applied to the ring $\mathbb{Z}[\omega]$ of Eisenstein integers answers the analogous question for $x^2 + xy + y^2$. Finally, the ring $\mathbb{Z}[\sqrt{-5}]$ shows that unique factorisation, on which everything here rests, can fail; measuring this failure is one of the origins of algebraic number theory.

Recall that $\mathbb{Z}[i]$ is a Euclidean domain, hence a UFD, with multiplicative norm $N(a+bi) = a^2 + b^2$ and units ± 1, $\pm i$ (Section 10.5). Two elements are *associates* if they differ by a unit factor; in a UFD every nonzero nonunit is a product of primes, unique up to order and associates (Theorem 8.5.4), and irreducible elements are prime. An element whose norm is a rational prime is irreducible: if $z = uv$, then $N(u)N(v)$ is prime, so $N(u) = 1$ or $N(v) = 1$.

Theorem 10.7.1 (Gaussian primes)**.** *Up to associates, the primes of $\mathbb{Z}[i]$ are:*

1. $1 + i$, *with* $2 = -i(1+i)^2$;
2. *the rational primes* $q \equiv 3 \pmod 4$;
3. *for each rational prime* $p \equiv 1 \pmod 4$, *written* $p = a^2 + b^2$, *the two elements* $a + bi$ *and* $a - bi$, *which are not associates, with* $p = (a+bi)(a-bi)$.

Proof. The elements listed are prime. $N(1+i) = 2$ and $N(a \pm bi) = p$ are rational primes, so these elements are irreducible, hence prime. A rational prime $q \equiv 3 \pmod 4$ is irreducible in $\mathbb{Z}[i]$: if $q = zw$ with nonunits, then $q^2 = N(z)N(w)$ forces $N(z) = q$, so q would be a sum of two squares, contradicting Theorem 10.5.1. The associates of $a + bi$ are $a + bi$, $-a - bi$, $-b + ai$ and $b - ai$; if $a - bi$ were one of them, then $b = 0$, or $a = 0$, or $a = \pm b$, and $p = a^2 + b^2$ would be a square or even, which it is not.

Every prime is associate to one of them. Let π be a prime of $\mathbb{Z}[i]$. Then π divides $N(\pi) = \pi\bar{\pi}$, a positive integer greater than 1; factoring it into rational primes, π divides one of them, say p. Then $N(\pi)$ divides $N(p) = p^2$, so $N(\pi) = p$ or p^2. If $N(\pi) = p^2$, then p/π has norm 1, so π is associate to p, and p is prime in $\mathbb{Z}[i]$; this excludes $p = 2 = -i(1+i)^2$ and $p \equiv 1 \pmod 4$, which are products of two nonunits, so $p \equiv 3 \pmod 4$. If $N(\pi) = p$, then p is a sum of two squares, so $p = 2$ or $p \equiv 1 \pmod 4$. For $p = 2$, $\pi = x + yi$ with $x^2 + y^2 = 2$, so $x, y = \pm 1$ and π is associate to $1 + i$. For $p \equiv 1 \pmod 4$, π divides $p = (a+bi)(a-bi)$, hence divides one of the two factors, which has the same norm; so π is associate to $a + bi$ or to $a - bi$. □

So a rational prime p behaves in one of three ways in $\mathbb{Z}[i]$: it *ramifies* ($p = 2$ becomes a unit times the square of a prime), it stays *inert* ($p \equiv 3 \pmod 4$ remains prime), or it *splits* into two non-associate primes ($p \equiv 1 \pmod 4$). Which case occurs is decided by p modulo 4, that is, by the Legendre symbol $(\frac{-1}{p})$ (Corollary 10.4.3); this is the simplest instance of a *reciprocity law*, describing the factorisation of primes in an extension by congruence conditions.

Example 10.7.2. To factor $z = 7 + i$, factor its norm: $N(z) = 50 = 2 \cdot 5^2$. So z is divisible by $1 + i$ and by two primes of norm 5, each associate to $2 + i$ or $2 - i$. Indeed $(7+i)/(1+i) = (7+i)(1-i)/2 = 4 - 3i$, and $4 - 3i = -i(3+4i) = -i(2+i)^2$, so

$$7 + i = -i(1+i)(2+i)^2.$$

Note that $2 - i$ does not divide $7 + i$, although it divides $N(7+i)$: the two primes above 5 must be kept apart. As an application, $7 + i$ is not a square times a unit, although its norm 50 is twice a square.

The factorisation counts the representations of an integer as a sum of two squares, refining Theorem 10.5.3. Let $r_2(n)$ be the number of pairs $(x, y) \in \mathbb{Z}^2$ with $x^2 + y^2 = n$, signs and order counted; and let χ be the function on positive integers with $\chi(d) = 0$ for even d, $\chi(d) = 1$ for $d \equiv 1 \pmod 4$ and $\chi(d) = -1$ for $d \equiv 3 \pmod 4$. It is completely multiplicative, since the product of two odd numbers is $\equiv 1 \pmod 4$ exactly when both or neither are $\equiv 3 \pmod 4$.

Theorem 10.7.3 (Jacobi's two squares theorem)**.** *For every $n \geq 1$,*

$$r_2(n) = 4 \sum_{d \mid n} \chi(d) = 4\big(d_1(n) - d_3(n)\big),$$

where $d_1(n)$ and $d_3(n)$ are the numbers of positive divisors of n congruent to 1 and to 3 modulo 4.

Proof. $r_2(n)$ is the number of $z \in \mathbb{Z}[i]$ with $N(z) = n$. Write $n = 2^e \prod_j p_j^{a_j} \prod_k q_k^{b_k}$ with distinct primes $p_j \equiv 1$ and $q_k \equiv 3 \pmod 4$, and choose primes π_j with $p_j = \pi_j \bar{\pi}_j$ (Theorem 10.7.1). By unique factorisation, every nonzero z is uniquely

$$z = u(1+i)^{e'} \prod_j \pi_j^{s_j} \bar{\pi}_j^{t_j} \prod_k q_k^{c_k} \cdot w,$$

with u a unit and w a product of primes not dividing n, and then $N(z) = 2^{e'} \prod_j p_j^{s_j+t_j} \prod_k q_k^{2c_k} N(w)$. So $N(z) = n$ if and only if $w = 1$, $e' = e$, $s_j + t_j = a_j$ and $2c_k = b_k$. If some b_k is odd there is no solution; otherwise there are 4 choices of u and $a_j + 1$ choices of (s_j, t_j) for each j, so $r_2(n) = 4 \prod_j (a_j + 1)$.

On the other side, $\chi * \mathbf{1}$, $n \mapsto \sum_{d \mid n} \chi(d)$, is multiplicative (Proposition 10.6.2(3)), and on prime powers it takes the values $\sum_{i=0}^{e} \chi(2^i) = 1$, $\sum_{i=0}^{a} \chi(p^i) = a + 1$ for $p \equiv 1 \pmod 4$, and $\sum_{i=0}^{b} (-1)^i$, which is 1 for even b and 0 for odd b, for $q \equiv 3 \pmod 4$. The product of these values is $\prod_j (a_j + 1)$ if all b_k are even and 0 otherwise. □

Example 10.7.4. $r_2(5) = 4(2 - 0) = 8$: $(\pm 1, \pm 2)$, $(\pm 2, \pm 1)$. $r_2(25) = 4 \cdot 3 = 12$: $(0, \pm 5)$, $(\pm 5, 0)$, $(\pm 3, \pm 4)$, $(\pm 4, \pm 3)$. $r_2(9) = 4(2 - 1) = 4$: only $(\pm 3, 0)$ and $(0, \pm 3)$, as $9 = 3^2$ with 3 inert. $r_2(3) = 4(1 - 1) = 0$. A pretty consequence, which uses areas and is only sketched here: $\sum_{n \leq N} r_2(n)$ counts the points of $\mathbb{Z}^2$ in the disc of radius $\sqrt{N}$, about πN of them, while by the theorem it equals $4 \sum_{d \leq N} \chi(d) \lfloor N/d \rfloor$, which is about $4N(1 - \frac{1}{3} + \frac{1}{5} - \cdots)$; this is how Gauss's circle problem yields Leibniz's series $1 - \frac{1}{3} + \frac{1}{5} - \cdots = \frac{\pi}{4}$.

10.7.1 Eisenstein integers

Let $\omega = e^{2\pi i/3} = \frac{-1+\sqrt{-3}}{2}$, a root of $x^2 + x + 1$, so that $\omega^2 = -1 - \omega = \bar{\omega}$. The ring of *Eisenstein integers* is $\mathbb{Z}[\omega] = \{a + b\omega : a, b \in \mathbb{Z}\}$; it is closed under multiplication because $\omega^2 = -1 - \omega$. Its elements form the triangular lattice in $\mathbb{C}$, and the norm is

$$N(a + b\omega) = |a + b\omega|^2 = (a + b\omega)(a + b\bar{\omega}) = a^2 - ab + b^2,$$

using $\omega + \bar{\omega} = -1$ and $\omega\bar{\omega} = 1$. It is multiplicative, with values in $\mathbb{N}$. Note that $\sqrt{-3} = 1 + 2\omega \in \mathbb{Z}[\omega]$.

Proposition 10.7.5. *1. $\mathbb{Z}[\omega]$ is a Euclidean domain for N, hence a UFD.*

2. Its units are the six elements ± 1, $\pm\omega$, $\pm\omega^2$ of norm 1, the sixth roots of unity.

3. Up to associates its primes are: $1 - \omega$, with $3 = -\omega^2(1 - \omega)^2$; the rational primes $q \equiv 2 \pmod 3$; and for each rational prime $p \equiv 1 \pmod 3$ two non-associate primes π, $\bar{\pi}$ with $p = \pi\bar{\pi}$.

Proof. (1) Let $a, b \in \mathbb{Z}[\omega]$ with $b \neq 0$, and write $a/b = u + v\omega$ with $u, v \in \mathbb{R}$ (possible since 1 and ω are a basis of $\mathbb{C}$ over $\mathbb{R}$). Choose integers m, n with $|u - m|, |v - n| \leq \frac{1}{2}$, and put $q = m + n\omega$, $r = a - qb$. With $s = u - m$ and $t = v - n$, $|a/b - q|^2 = s^2 - st + t^2 \leq \frac{1}{4} + \frac{1}{4} + \frac{1}{4} < 1$, so $N(r) < N(b)$. A Euclidean domain is a UFD (Theorem 8.5.4).

(2) As for $\mathbb{Z}[i]$, the units are the elements of norm 1. From $4(a^2-ab+b^2) = (2a-b)^2+3b^2 = 4$ we get $b \in \{0, \pm 1\}$, and the solutions are ± 1, $\pm\omega$ and $\pm(1+\omega) = \mp\omega^2$.

(3) Since $1-\omega$ has norm $1+1+1 = 3$, it is prime, and $(1-\omega)^2 = 1-2\omega+\omega^2 = -3\omega$, so $3 = -\omega^2(1-\omega)^2$. The values of the norm modulo 3: $4N(a+b\omega) = (2a-b)^2+3b^2 \equiv (2a-b)^2 \pmod 3$, which is 0 or 1; as $4 \equiv 1$, no norm is $\equiv 2 \pmod 3$. Hence a rational prime $q \equiv 2 \pmod 3$ is prime in $\mathbb{Z}[\omega]$, by the argument used for $\mathbb{Z}[i]$. Let $p \equiv 1 \pmod 3$. By quadratic reciprocity (Theorem 10.4.9) and Corollary 10.4.3,

$$\left(\frac{-3}{p}\right) = \left(\frac{-1}{p}\right)\left(\frac{3}{p}\right) = (-1)^{\frac{p-1}{2}} \cdot (-1)^{\frac{p-1}{2}} \left(\frac{p}{3}\right) = \left(\frac{p}{3}\right) = \left(\frac{1}{3}\right) = 1,$$

using that the Legendre symbol is multiplicative (Proposition 10.4.2). So there is x with $p \mid x^2+3 = (x+\sqrt{-3})(x-\sqrt{-3})$. Now p divides neither factor: $(x \pm \sqrt{-3})/p = (x \pm 1)/p \pm (2/p)\omega$ does not lie in $\mathbb{Z}[\omega]$, as p is odd. So p is not prime, $p = \pi\pi'$ with nonunits, and $N(\pi) = p$, so π is prime and $p = \pi\bar{\pi}$.

$\pi = a+b\omega$ and $\bar{\pi}$ are not associates. Otherwise π divides $\bar{\pi}$, hence the integer $\pi+\bar{\pi} = 2a-b$ and the element $\pi - \bar{\pi} = b(\omega - \bar{\omega}) = b\sqrt{-3}$. If π divides an element z, then $p = N(\pi)$ divides $N(z)$; so $p \mid (2a-b)^2$ and $p \mid 3b^2$, hence $p \mid b$ (as $p \neq 3$), then $p \mid 2a$ and $p \mid a$. But then $p^2 \mid a^2 - ab + b^2 = p$, which is absurd.

Finally let π be any prime. As in Theorem 10.7.1, π divides a rational prime p, and $N(\pi) = p$ or p^2. If $N(\pi) = p^2$, then π is associate to p, so p is prime in $\mathbb{Z}[\omega]$; this excludes $p = 3$ and $p \equiv 1 \pmod 3$, which are products of two nonunits, so $p \equiv 2 \pmod 3$. If $N(\pi) = p$, then $p \not\equiv 2 \pmod 3$; for $p = 3$, π divides $(1-\omega)^2$, hence is associate to $1-\omega$, and for $p \equiv 1 \pmod 3$, π divides one of the two primes of norm p found above and is associate to it. □

Corollary 10.7.6. *A prime p can be written as $p = x^2+xy+y^2$ with $x, y \in \mathbb{Z}$ if and only if $p = 3$ or $p \equiv 1 \pmod 3$; and as $p = x^2+3y^2$ if and only if $p = 3$ or $p \equiv 1 \pmod 3$.*

Proof. $a^2 - ab + b^2 = x^2 + xy + y^2$ with $x = a$, $y = -b$, so the primes of the first form are the norms of elements of $\mathbb{Z}[\omega]$, which by the proposition are 3 and the $p \equiv 1 \pmod 3$. For the second form: $3 = 0^2+3\cdot 1^2$, and $x^2+3y^2 = N(x+y\sqrt{-3})$ is a norm, so the condition is necessary. Conversely let $p \equiv 1 \pmod 3$ and $p = N(a+b\omega)$. Among the six associates $\varepsilon(a+b\omega)$ choose one, $c+d\omega$, with d even: multiplying by ω sends $a+b\omega$ to $a\omega+b\omega^2 = -b+(a-b)\omega$, so the second coordinates of $a+b\omega$, $\omega(a+b\omega)$, $\omega^2(a+b\omega)$ are b, $a-b$, $-a$, and one of b, $a-b$, a is even. Then $c+d\omega = (c-d/2)+(d/2)\sqrt{-3}$, and $p = (c-d/2)^2+3(d/2)^2$. □

For example $7 = 2^2+2+1 = 2^2+3\cdot 1^2$, $13 = 3^2+3+1 = 1^2+3\cdot 2^2$, $31 = 5^2+5+1 = 2^2+3\cdot 3^2$, while 5, 11, 17 are of neither form. The ring $\mathbb{Z}[\omega]$ is the setting of Euler's proof of Fermat's last theorem for exponent 3, and its sixfold symmetry is that of the hexagonal lattice and of the elliptic curve $\mathbb{C}/\mathbb{Z}[\omega]$ (Chapter 61).

10.7.2 Failure of unique factorisation

Example 10.7.7. In $\mathbb{Z}[\sqrt{-5}] = \{a+b\sqrt{-5} : a, b \in \mathbb{Z}\}$, with multiplicative norm $N(a+b\sqrt{-5}) = a^2+5b^2$,

$$6 = 2\cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$$

are two factorisations into irreducible elements that do not correspond to each other. The norms of 2, 3, $1 \pm \sqrt{-5}$ are 4, 9, 6, 6. The units are ± 1, the only elements of norm 1. A proper factor of one of these four elements would have norm 2 or 3, but a^2+5b^2 never equals 2 or 3 (if $b \neq 0$ it is at least 5). So all four are irreducible, and 2 is not associate to $1 \pm \sqrt{-5}$, having a different norm. Hence $\mathbb{Z}[\sqrt{-5}]$ is not a UFD, and 2 is irreducible but not prime: it divides $(1+\sqrt{-5})(1-\sqrt{-5})$ but neither factor.

Kummer and Dedekind restored unique factorisation by passing from elements to *ideals*: in $\mathbb{Z}[\sqrt{-5}]$ the ideals $\mathfrak{p} = (2, 1+\sqrt{-5})$, $\mathfrak{q} = (3, 1+\sqrt{-5})$ and $\bar{\mathfrak{q}} = (3, 1-\sqrt{-5})$ are prime, and $(6) = \mathfrak{p}^2\mathfrak{q}\bar{\mathfrak{q}}$, with $(2) = \mathfrak{p}^2$, $(3) = \mathfrak{q}\bar{\mathfrak{q}}$ and $(1 \pm \sqrt{-5}) = \mathfrak{p}\mathfrak{q}$ or $\mathfrak{p}\bar{\mathfrak{q}}$; the two factorisations of 6 are two groupings of the same four prime ideals. The failure of unique factorisation of elements is measured by the *class group*, the group of ideals modulo principal ideals, which is finite; its order, the *class number*, is 2 for $\mathbb{Z}[\sqrt{-5}]$. We do not develop ideal theory here and only state these facts [IR90]; ideals of rings are studied in Chapter 14. The next section computes class numbers in the equivalent language of quadratic forms, which is how Gauss found them.

10.8 Binary quadratic forms

Fermat's theorem says which primes are $x^2 + y^2$, and Corollary 10.7.6 which are $x^2 + xy + y^2$ and $x^2 + 3y^2$. What about $x^2 + 5y^2$? The primes $29 = 3^2 + 5 \cdot 2^2$ and $41 = 6^2 + 5 \cdot 1^2$ are of this form, but 3 and 7 are not, although -20 is a square modulo 3 and 7. They are represented instead by the form $2x^2 + 2xy + 3y^2$, at $(x, y) = (0, 1)$ and $(1, 1)$. Lagrange and Gauss understood that one should study all forms of a given discriminant at once, up to changes of variables. This theory, reduction of forms and the class number, explains the examples, and leads to Euler's famous prime-producing polynomial $n^2 + n + 41$ and to the Heegner numbers.

Definition 10.8.1. A *binary quadratic form* is $f(x, y) = ax^2 + bxy + cy^2$ with $a, b, c \in \mathbb{Z}$, written $f = (a, b, c)$. Its *discriminant* is $D = b^2 - 4ac$. The form is *positive definite* if $f(x, y) > 0$ for all $(x, y) \in \mathbb{R}^2 \setminus \{0\}$. An integer m is *represented* by f if $m = f(x, y)$ with $x, y \in \mathbb{Z}$, and *properly* represented if moreover $\gcd(x, y) = 1$. Two forms f and g are *equivalent* if $g(x, y) = f(px + qy, rx + sy)$ for some integers p, q, r, s with $ps - qr = 1$, that is, for a matrix in $\mathrm{SL}_2(\mathbb{Z})$.

The discriminant satisfies $D \equiv b^2 \equiv 0$ or $1 \pmod 4$. Completing the square, $4a f(x, y) = (2ax + by)^2 - Dy^2$; so f is positive definite if and only if $D < 0$ and $a > 0$, and then $c > 0$ as well. Equivalence is an equivalence relation, because $\mathrm{SL}_2(\mathbb{Z})$ is a group; it preserves the discriminant, and equivalent forms represent the same integers, properly or not, since a matrix in $\mathrm{SL}_2(\mathbb{Z})$ permutes $\mathbb{Z}^2$ and the primitive vectors. In matrix terms, $f(x, y) = (x\ y)\, M_f\, (x\ y)^T$ with $M_f = \left(\begin{smallmatrix} a & b/2 \\ b/2 & c \end{smallmatrix}\right)$, $D = -4 \det M_f$, and substituting $(x, y)^T \mapsto P(x, y)^T$ replaces M_f by $P^T M_f P$, which has the same determinant. Two substitutions are used constantly:

$$(a, b, c) \sim (a, b+2at, at^2+bt+c) \quad \big(x \mapsto x+ty\big), \qquad (a, b, c) \sim (c, -b, a) \quad \big((x, y) \mapsto (-y, x)\big).$$

Definition 10.8.2. A positive definite form (a, b, c) is *reduced* if $|b| \le a \le c$, and $b \ge 0$ whenever $|b| = a$ or $a = c$.

Theorem 10.8.3 (Lagrange, Gauss)**.** *Every positive definite form is equivalent to exactly one reduced form. If (a, b, c) is reduced of discriminant D, then $a \le \sqrt{|D|/3}$; hence there are only finitely many reduced forms of a given discriminant.*

Proof. Existence. Let $f = (a, b, c)$ be positive definite. Using the first substitution with a suitable t we can achieve $|b| \le a$, since $b + 2at$ runs through a residue class modulo $2a$. If then $a > c$, the second substitution replaces a by the smaller positive integer c. Alternate these two steps; since a decreases strictly at each use of the second step, after finitely many steps $|b| \le a \le c$. Finally, if $b = -a$, the first substitution with $t = 1$ gives (a, a, c) (as $a - a + c = c$); and if $a = c$ and $b < 0$, the second gives $(a, -b, a)$. The result is reduced.

The bound. If $|b| \le a \le c$, then $|D| = 4ac - b^2 \ge 4a^2 - a^2 = 3a^2$.

Uniqueness. Let $f = (a, b, c)$ satisfy $|b| \le a \le c$. For integers x, y: if $|x| \ge |y|$, then $f(x, y) \ge ax^2 - |b||x||y| + cy^2 \ge (a - |b|)x^2 + cy^2$, and if $|y| \ge |x|$, similarly $f(x, y) \ge ax^2 + (c - |b|)y^2$. Hence $f(x, y) \ge a$ if $(x, y) \ne 0$, $f(x, y) \ge c$ if $y \ne 0$ (for $x = 0$ this is $cy^2 \ge c$, and for $xy \ne 0$ both bounds give at least $a - |b| + c \ge c$), and, when $|b| < a < c$, $f(x, y) > a$ for all $(x, y) \ne (\pm 1, 0)$, the bound for $xy \ne 0$ then being $a - |b| + c > c > a$.

Consequently a is the smallest nonzero value of f on $\mathbb{Z}^2$, and c is the smallest value $f(w)$ for w linearly independent of a vector v with $f(v) = a$. (For $v = (1, 0)$ the vectors w independent of v have $y \ne 0$, so $f(w) \ge c = f(0, 1)$. If $f(v) = a$ with $v = (x, y)$, $y \ne 0$, then $a = f(v) \ge c$, so $a = c$, every w has $f(w) \ge a = c$, and $w = (1, 0)$ is independent of v with $f(w) = c$.) These two numbers are unchanged by an equivalence, which maps $\mathbb{Z}^2$ bijectively to itself and preserves linear independence. So equivalent reduced forms have the same a and c, hence the same $|b| = \sqrt{D + 4ac}$.

It remains to exclude that (a, b, c) and $(a, -b, c)$, with $b > 0$, are both reduced and equivalent. If $(a, -b, c)$ is reduced, then $|b| < a < c$ by the sign condition. Suppose $(a, b, c)(x, y) = g(px + qy, rx + sy)$ with $g = (a, -b, c)$ and $ps - qr = 1$. Taking $(x, y) = (1, 0)$ gives $g(p, r) = a$, so $(p, r) = \pm(1, 0)$ by the strict inequality above, applied to g. Then $ps = 1$ gives $s = p = \pm 1$, and the substitution is $\pm(x + q'y, y)$ with $q' = \pm q$; as $g(-v) = g(v)$, (a, b, c) is obtained from g by the first substitution with $t = q'$, so $b = -b + 2aq'$. Then $2|b| = 2a|q'|$ with $0 < |b| < a$, which is impossible. □

The number of reduced forms of discriminant D is called the *class number* $h(D)$ (often one counts only *primitive* forms, with $\gcd(a, b, c) = 1$; for the discriminants below the two counts agree unless noted). The reduced forms are found by a finite search: $b \equiv D \pmod 2$, $|b| \le a \le \sqrt{|D|/3}$, and $c = (b^2 - D)/4a$ must be an integer with $c \ge a$.

Example 10.8.4.

1. $D = -4$: $a \le 1$, so $(a, b, c) = (1, 0, 1)$, and $h(-4) = 1$. $D = -3$: $(1, 1, 1)$. $D = -8$: $a \le 1$, $b = 0$, $(1, 0, 2)$. $D = -7$: $(1, 1, 2)$. So each of these discriminants has the single reduced form $x^2 + y^2$, $x^2 + xy + y^2$, $x^2 + 2y^2$, $x^2 + xy + 2y^2$ respectively.

2. $D = -12$: $a \le 2$; $a = 1$ gives $(1, 0, 3)$; $a = 2$ requires $b \in \{0, 2\}$ and $c = (b^2 + 12)/8$, which gives $(2, 2, 2)$. This form is not primitive and represents only even numbers; the primitive class number is $h(-12) = 1$.

3. $D = -20$: $a \le 2$; $(1, 0, 5)$, and for $a = 2$, $b \in \{0, 2\}$ with $c = (b^2 + 20)/8$, giving $(2, 2, 3)$. So $h(-20) = 2$, with the forms $x^2 + 5y^2$ and $2x^2 + 2xy + 3y^2$, matching the class number 2 of $\mathbb{Z}[\sqrt{-5}]$ in Example 10.7.7.

4. $D = -23$: $a \le 2$, b odd; $b = \pm 1$, $ac = 6$: $(1, 1, 6)$, $(2, 1, 3)$, $(2, -1, 3)$, all reduced (for $a = 2$ we have $|b| < a < c$, so both signs are allowed). So $h(-23) = 3$: the forms $2x^2 \pm xy + 3y^2$ are *improperly* equivalent (by $(x, y) \mapsto (x, -y)$) but not equivalent under $\mathrm{SL}_2(\mathbb{Z})$.

To connect forms with primes we need to know which forms represent a given number.

Lemma 10.8.5. *Let $D < 0$ and $m \ge 1$. Then m is properly represented by some form of discriminant D if and only if $D \equiv b^2 \pmod{4m}$ for some integer b. More precisely, if $D = b^2 - 4mc$, then m is properly represented by (m, b, c); and if $f(x_0, y_0) = m$ with $\gcd(x_0, y_0) = 1$, then f is equivalent to a form (m, b, c).*

Proof. If $D = b^2 - 4mc$, then (m, b, c) has discriminant D and $m = f(1, 0)$. Conversely let $f(x_0, y_0) = m$ with $\gcd(x_0, y_0) = 1$. By Bézout's identity choose q, s with $x_0 s - q y_0 = 1$; the substitution $(x, y) \mapsto (x_0 x + qy, y_0 x + sy)$ lies in $\mathrm{SL}_2(\mathbb{Z})$ and transforms f into a form g with $g(1, 0) = f(x_0, y_0) = m$, that is, $g = (m, b, c)$, and $D = b^2 - 4mc \equiv b^2 \pmod{4m}$. □

Corollary 10.8.6. *Let $D < 0$ be a discriminant such that the only reduced form of discriminant D is f_0. Then a prime p is represented by f_0 if and only if D is a square modulo $4p$. In particular:*

1. *(Fermat) an odd prime p is $x^2 + y^2$ if and only if $p \equiv 1 \pmod 4$;*
2. *an odd prime p is $x^2 + 2y^2$ if and only if $p \equiv 1, 3 \pmod 8$;*
3. *a prime $p \neq 7$ is $x^2 + xy + 2y^2$, equivalently $x^2 + 7y^2$ when p is odd, if and only if $(\frac{p}{7}) = 1$, that is, $p \equiv 1, 2, 4 \pmod 7$.*

Proof. A prime is properly represented whenever it is represented, since $f(x, y) = p$ forces $\gcd(x, y)^2 \mid p$. So by Lemma 10.8.5, p is represented by some form of discriminant D if and only if D is a square modulo $4p$; and every such form is equivalent to its reduced form f_0 (Theorem 10.8.3), which represents the same numbers.

For odd p, $D \equiv b^2 \pmod{4p}$ has a solution if and only if D is a square modulo p: given $D \equiv b^2 \pmod p$ we may change b by p to make $b \equiv D \pmod 2$, and then $b^2 \equiv D \pmod 4$ as well (both sides are $\equiv 0$ or $\equiv 1 \pmod 4$ according to their parity), so $b^2 \equiv D \pmod{4p}$ by the Chinese remainder theorem. Now (1) is $D = -4$, where -4 is a square modulo p if and only if -1 is (Corollary 10.4.3). For (2), $D = -8$ and $(\frac{-2}{p}) = (\frac{-1}{p})(\frac{2}{p})$ equals 1 exactly for $p \equiv 1, 3 \pmod 8$, by Corollary 10.4.3 and Proposition 10.4.7. For (3), $D = -7$; for odd $p \neq 7$, reciprocity gives $(\frac{-7}{p}) = (-1)^{\frac{p-1}{2}}(\frac{7}{p}) = (-1)^{\frac{p-1}{2}}(-1)^{\frac{p-1}{2}\cdot 3}(\frac{p}{7}) = (\frac{p}{7})$, and the squares modulo 7 are $1, 2, 4$. For $p = 2$, $-7 \equiv 1 = 1^2 \pmod 8$ and $2 = x^2 + xy + 2y^2$ with $(x, y) = (0, 1)$, consistent with $2 \equiv 2 \pmod 7$. Finally, for odd values, $4(x^2 + xy + 2y^2) = (2x + y)^2 + 7y^2$, and $p = x^2 + xy + 2y^2$ odd forces y even (if y were odd, $x^2 + xy = x(x + y)$ would be even and the value even), so $p = (x + y/2)^2 + 7(y/2)^2$; conversely $x^2 + 7y^2 = (x - y)^2 + (x - y)(2y) + 2(2y)^2$. □

When $h(D) > 1$ the corollary only says that p is represented by *one of* the reduced forms. For $D = -20$, an odd prime $p \neq 5$ is represented by $x^2 + 5y^2$ or by $2x^2 + 2xy + 3y^2$ exactly when $(\frac{-5}{p}) = 1$, that is (by reciprocity) when $p \equiv 1, 3, 7, 9 \pmod{20}$. Congruences separate the two forms: $x^2 + 5y^2$ takes odd prime values only $\equiv 1, 9 \pmod{20}$, and $2x^2 + 2xy + 3y^2$ only $\equiv 3, 7 \pmod{20}$ (Exercise 10.9.15). So $p = x^2 + 5y^2$ if and only if $p \equiv 1, 9 \pmod{20}$, as Euler conjectured. For $D = -23$ no such congruence description exists for $x^2 + xy + 6y^2$; the answer requires class field theory [Cox89].

10.8.1 Euler's polynomial and the Heegner numbers

Euler observed in 1772 that $n^2 + n + 41$ is prime for $n = 0, 1, \ldots, 39$: the values are $41, 43, 47, 53, 61, 71, \ldots, 1601$. (For $n = 40$ the value is 41^2.) The explanation is that -163, the discriminant of $x^2 + xy + 41y^2$, has class number one.

Theorem 10.8.7 (Rabinowitsch)**.** *Let p be a prime and $D = 1 - 4p$. The following are equivalent:*

1. *the only reduced form of discriminant D is $x^2 + xy + py^2$;*
2. *$n^2 + n + p$ is prime for $n = 0, 1, \ldots, p - 2$.*

Proof. Note $4(n^2 + n + p) = (2n + 1)^2 - D$.

(1) $\Rightarrow$ (2). Let $0 \leq n \leq p - 2$ and $N = n^2 + n + p$, and suppose N is not prime. Then it has a prime factor $q \leq \sqrt{N}$, and $N \leq (p - 2)^2 + (p - 2) + p = p^2 - 2p + 2 < p^2$, so $q < p$. Since $q \mid N$, $(2n + 1)^2 - D = 4N$ is divisible by $4q$, and $(q, 2n + 1, N/q)$ is a form of discriminant D representing q. By (1) and Theorem 10.8.3 it is equivalent to $x^2 + xy + py^2$, so $q = x^2 + xy + py^2$ for some integers x, y. If $y = 0$, $q = x^2$ is not prime. If $y \neq 0$,

$$q = \left(x + \frac{y}{2}\right)^2 + \frac{4p - 1}{4}y^2 \geq \frac{4p - 1}{4} > p - 1,$$

so $q \geq p$, a contradiction.

(2) $\Rightarrow$ (1). Let (a, b, c) be reduced of discriminant D. Then b is odd, $b = \pm(2n+1)$ with $n \geq 0$, and $ac = (b^2 - D)/4 = n^2 + n + p$. By Theorem 10.8.3, $2n + 1 = |b| \leq a \leq \sqrt{(4p-1)/3}$, so $n < \sqrt{p/3} \leq p - 2$ for $p \geq 3$, while for $p = 2$ the bound gives $n = 0$. So ac is prime by (2), and $a \leq c$ forces $a = 1$, hence $|b| \leq 1$, $b = 1$ (the sign condition for $|b| = a$), and $c = p$. □

Corollary 10.8.8. *$n^2 + n + 41$ is prime for $n = 0, 1, \ldots, 39$.*

Proof. We check condition (1) of Theorem 10.8.7 for $D = -163$. A reduced form (a, b, c) has b odd, $|b| \leq a \leq \sqrt{163/3} < 8$, and $ac = (b^2 + 163)/4$. For $b = \pm 1, \pm 3, \pm 5, \pm 7$ this is 41, 43, 47, 53, all prime; as $a \leq c$, $a = 1$, and then $|b| \leq 1$ and $b = 1$. So $(1, 1, 41)$ is the only reduced form. □

Forty values were checked by an argument involving eight. The same computation applies to $p = 2, 3, 5, 11, 17, 41$, with $D = -7, -11, -19, -43, -67, -163$ (Exercise 10.9.17).

Remark 10.8.9.

1. *The Heegner numbers.* The negative discriminants D for which every primitive positive definite form is equivalent to the principal one, $x^2 - \frac{D}{4}y^2$ or $x^2 + xy + \frac{1-D}{4}y^2$, are exactly

$$D = -3, -4, -7, -8, -11, -12, -16, -19, -27, -28, -43, -67, -163.$$

Equivalently, the imaginary quadratic fields $\mathbb{Q}(\sqrt{-d})$, $d > 0$ squarefree, whose ring of integers is a UFD are those with $d \in \{1, 2, 3, 7, 11, 19, 43, 67, 163\}$, the *Heegner numbers*. Gauss conjectured that the list is complete; it was proved by Heegner in 1952, whose argument was long considered incomplete, and by Baker and Stark in 1966–1967 [Cox89]. Combined with Theorem 10.8.7, it determines the primes p for which $n^2 + n + p$ is prime for $0 \leq n \leq p - 2$: $1 - 4p$ must be one of the odd discriminants in the list, which gives $p \in \{2, 3, 5, 7, 11, 17, 41\}$, and $p = 7$ fails because of the non-primitive reduced form $(3, 3, 3)$ of discriminant -27 (indeed $1 + 1 + 7 = 9$). So the primes are $2, 3, 5, 11, 17, 41$, and Euler's 41 is the largest.

2. *An almost integer.* The number $e^{\pi\sqrt{163}} = 262537412640768743.99999999999925\ldots$ is extraordinarily close to the integer $640320^3 + 744$. The reason is again $h(-163) = 1$: the j-invariant of the elliptic curve $\mathbb{C}/\mathbb{Z}[\frac{1+\sqrt{-163}}{2}]$ is then an integer, equal to -640320^3, and the expansion $j(\tau) = e^{-2\pi i\tau} + 744 + 196884e^{2\pi i\tau} + \cdots$ at $\tau = \frac{1+\sqrt{-163}}{2}$, where $e^{2\pi i\tau} = -e^{-\pi\sqrt{163}}$ is tiny, gives $-e^{\pi\sqrt{163}} + 744 \approx -640320^3$ [Cox89]. This is the theory of complex multiplication, which connects class numbers with elliptic curves (Chapter 61).

3. *Class numbers grow.* Although $h(D) = 1$ only finitely often, $h(D) \to \infty$ as $D \to -\infty$ (Heilbronn, 1934); roughly, $h(D)$ is of size $\sqrt{|D|}$. The class number is also given by Dirichlet's *class number formula*, which for $D < -4$ fundamental reads $h(D) = -\frac{1}{|D|}\sum_{m=1}^{|D|}\left(\frac{D}{m}\right)m$ with the Kronecker symbol [Cox89]; for $D = -23$ it gives 3.

10.9 Exercises

Exercise 10.9.1. Show that there are infinitely many primes $p \equiv 3 \pmod 4$. (Consider $N = 4p_1 \cdots p_k - 1$.)

Solution. Let $p_1, \ldots, p_k$ be primes $\equiv 3 \pmod 4$ and $N = 4p_1 \cdots p_k - 1 \equiv 3 \pmod 4$. N is odd, so its prime factors are $\equiv 1$ or $3 \pmod 4$; if all were $\equiv 1$, their product N would be $\equiv 1 \pmod 4$. So some prime $q \equiv 3 \pmod 4$ divides N, and $q \neq p_i$, since $p_i \mid N + 1$. □

Exercise 10.9.2. Show that an integer $n \geq 2$ is prime if and only if $(n-1)! \equiv -1 \pmod{n}$.

Solution. If n is prime this is Wilson's theorem (Corollary 7.3.5). If $n = ab$ with $1 < a < n$, then a divides $(n-1)!$, so if $n \mid (n-1)! + 1$, then a divides $(n-1)! + 1$ and hence 1, which is absurd. □

Exercise 10.9.3. Let $p \equiv 1 \pmod{4}$ be prime. Show that $x = \left(\frac{p-1}{2}\right)!$ satisfies $x^2 \equiv -1 \pmod{p}$.

Solution. Let $h = \frac{p-1}{2}$. Pairing k with $p - k \equiv -k$, Wilson's theorem gives $-1 \equiv (p-1)! = \prod_{k=1}^{h} k(p-k) \equiv \prod_{k=1}^{h}(-k^2) = (-1)^h (h!)^2 \pmod{p}$. As h is even, $(h!)^2 \equiv -1$. □

Exercise 10.9.4. Show that $\varphi(n)$ is even for $n \geq 3$, and that $\varphi(n) \geq \sqrt{n/2}$ for all $n \geq 1$.

Solution. For $n \geq 3$ the map $a \mapsto n - a$ is an involution of the set of $1 \leq a < n$ prime to n without fixed points: $a = n - a$ would mean $n = 2a$, and then $\gcd(a, n) = a = 1$ forces $n = 2$. So the set has an even number of elements. For the inequality, by multiplicativity it suffices to note that $\varphi(p^k) = p^{k-1}(p-1) \geq \sqrt{p^k}$ for odd p (as $p - 1 \geq \sqrt{p}$ for $p \geq 3$ and $p^{k-1} \geq p^{(k-1)/2}$), and $\varphi(2^k) = 2^{k-1} \geq \sqrt{2^k/2}$; multiplying over the prime powers in n, with the factor $1/\sqrt{2}$ appearing at most once, gives $\varphi(n) \geq \sqrt{n/2}$. □

Exercise 10.9.5. Give a second proof of Theorem 10.3.3: for $d \mid p-1$ let $\psi(d)$ be the number of elements of order d in U_p. Show that $\psi(d) \leq \varphi(d)$, using that $x^d - 1$ has at most d roots in $\mathbb{F}_p$, and deduce from Proposition 10.2.8(4) that $\psi(d) = \varphi(d)$, in particular $\psi(p-1) \geq 1$.

Solution. If there is an element x of order d, its powers $1, x, \ldots, x^{d-1}$ are d distinct roots of $x^d - 1$, hence all of its roots (Corollary 8.6.7); so every element of order d is a power of x, and those of order d are the x^k with $\gcd(k, d) = 1$ (Lemma 10.3.2(2)), $\varphi(d)$ in number. So $\psi(d) \in \{0, \varphi(d)\}$. Every element has an order dividing $p-1$, so $\sum_{d \mid p-1} \psi(d) = p - 1 = \sum_{d \mid p-1} \varphi(d)$. As $\psi(d) \leq \varphi(d)$ termwise, equality holds termwise. □

Exercise 10.9.6. Check that 14 is a primitive root modulo 29 and that $14^{28} \equiv 1 \pmod{29^2}$. Which of 14 and 43 is a primitive root modulo 29^2?

Solution. $29 - 1 = 28 = 2^2 \cdot 7$, so by Example 10.3.4(3) it suffices to check $14^{14} \not\equiv 1$ and $14^4 \not\equiv 1 \pmod{29}$. Modulo 29: $14^2 = 196 \equiv 22 \equiv -7$, $14^4 \equiv 49 \equiv 20$, $14^7 = 14^4 \cdot 14^2 \cdot 14 \equiv 20 \cdot (-7) \cdot 14 = -1960 \equiv -1960 + 68 \cdot 29 = 12$, and $14^{14} \equiv 144 \equiv -1$. So 14 is a primitive root. Modulo $841 = 29^2$: $14^2 = 196$, $14^4 = 38416 = 45 \cdot 841 + 571$, so $14^4 \equiv 571$; $14^7 = 14^4 \cdot 14^2 \cdot 14 \equiv 571 \cdot 196 \cdot 14$, and $571 \cdot 196 = 111916 = 133 \cdot 841 + 63$, so $14^7 \equiv 63 \cdot 14 = 882 \equiv 41$; $14^{14} \equiv 41^2 = 1681 = 2 \cdot 841 - 1 \equiv -1$, and $14^{28} \equiv 1 \pmod{841}$. So 14 is not a primitive root modulo 841, and by Theorem 10.3.7 $43 = 14 + 29$ is. □

Exercise 10.9.7. Show that for $k \geq 3$ the congruence $x^2 \equiv 1 \pmod{2^k}$ has exactly four solutions modulo 2^k, namely ± 1 and $\pm 1 + 2^{k-1}$, while for an odd prime p the congruence $x^2 \equiv 1 \pmod{p^k}$ has only the solutions ± 1. How many solutions does $x^2 \equiv 1 \pmod{n}$ have in general?

Solution. The solutions are the elements of order dividing 2 in U_{2^k}. By Theorem 10.3.9 this group is $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2^{k-2}\mathbb{Z}$, which has four such elements; and ± 1, $\pm 1 + 2^{k-1}$ are four distinct solutions, as $(\pm 1 + 2^{k-1})^2 = 1 \pm 2^k + 2^{2k-2} \equiv 1$ for $k \geq 2$, so they are all. For odd p, U_{p^k} is cyclic (Theorem 10.3.7) of even order, and has exactly two elements of order dividing 2 (Lemma 10.3.2(3)), namely ± 1. By the Chinese remainder theorem, if $n = 2^a p_1^{k_1} \cdots p_r^{k_r}$ with distinct odd primes p_i, the number of solutions is 2^r times 1, 2 or 4 according as $a \leq 1$, $a = 2$ or $a \geq 3$. □

Exercise 10.9.8. Show that for a prime $p > 3$, $\left(\frac{-3}{p}\right) = 1$ if and only if $p \equiv 1 \pmod 3$. Deduce that there are infinitely many primes $p \equiv 1 \pmod 3$ (consider $N = (2p_1 \cdots p_k)^2 + 3$).

Solution. By Euler's criterion, Corollary 10.4.3 and reciprocity, $(\frac{-3}{p}) = (\frac{-1}{p})(\frac{3}{p}) = (-1)^{\frac{p-1}{2}} \cdot (-1)^{\frac{p-1}{2}}(\frac{p}{3}) = (\frac{p}{3})$, which is 1 exactly when $p \equiv 1 \pmod 3$. Given primes $p_1, \ldots, p_k \equiv 1 \pmod 3$, let $N = (2p_1 \cdots p_k)^2 + 3$, which is odd and not divisible by 3 (it is $\equiv 1 \pmod 3$, as $p_i \neq 3$ and $4 \equiv 1$). A prime $q \mid N$ satisfies $q > 3$ and $x^2 \equiv -3 \pmod q$ with $x = 2p_1 \cdots p_k$, so $q \equiv 1 \pmod 3$; and $q \neq p_i$, as otherwise $q \mid 3$. □

Exercise 10.9.9. For an odd $n = p_1 \cdots p_r$ (primes not necessarily distinct) and any integer a, the *Jacobi symbol* is $(\frac{a}{n}) = \prod_i (\frac{a}{p_i})$. Show that it is multiplicative in a and in n, that $(\frac{-1}{n}) = (-1)^{(n-1)/2}$, $(\frac{2}{n}) = (-1)^{(n^2-1)/8}$, and $(\frac{m}{n})(\frac{n}{m}) = (-1)^{\frac{m-1}{2}\cdot\frac{n-1}{2}}$ for coprime odd positive m, n. Use it to compute $(\frac{1001}{9907})$ without factoring 1001, given that 9907 is prime. Show by an example that $(\frac{a}{n}) = 1$ does not imply that a is a square modulo n.

Solution. Multiplicativity in n is the definition, and in a follows from Proposition 10.4.2(3). The functions $u \mapsto (-1)^{(u-1)/2}$ and $u \mapsto (-1)^{(u^2-1)/8}$ are multiplicative on odd integers: for odd u, v, $\frac{uv-1}{2} - \frac{u-1}{2} - \frac{v-1}{2} = \frac{(u-1)(v-1)}{2} \equiv 0 \pmod 2$, and $\frac{u^2v^2-1}{8} - \frac{u^2-1}{8} - \frac{v^2-1}{8} = \frac{(u^2-1)(v^2-1)}{8} \equiv 0 \pmod 2$, as $8 \mid u^2 - 1$ (Example 10.2.2(2)). So the two supplementary laws pass from primes to products. Likewise $(m, n) \mapsto (-1)^{\frac{m-1}{2}\frac{n-1}{2}}$ is multiplicative in each variable, so reciprocity for the Jacobi symbol follows from the prime case by writing both m and n as products of primes. Now $1001 \equiv 1 \pmod 4$, so $(\frac{1001}{9907}) = (\frac{9907}{1001}) = (\frac{898}{1001}) = (\frac{2}{1001})(\frac{449}{1001})$. As $1001 \equiv 1 \pmod 8$, $(\frac{2}{1001}) = 1$, and $449 \equiv 1 \pmod 4$ gives $(\frac{449}{1001}) = (\frac{1001}{449}) = (\frac{103}{449}) = (\frac{449}{103}) = (\frac{37}{103}) = (\frac{103}{37}) = (\frac{29}{37}) = (\frac{37}{29}) = (\frac{8}{29}) = (\frac{2}{29})^3 = -1$, as $29 \equiv 5 \pmod 8$. So $(\frac{1001}{9907}) = -1$, and 1001 is not a square modulo 9907. Finally $(\frac{2}{15}) = (\frac{2}{3})(\frac{2}{5}) = (-1)(-1) = 1$, but 2 is not a square modulo 15, since it is not a square modulo 3. □

Exercise 10.9.10. Show that if $2^k - 1$ is prime, then k is prime. Show that every prime divisor q of $2^p - 1$, for p an odd prime, satisfies $q \equiv 1 \pmod{2p}$, and use this to show that $2^{11} - 1$ is composite and $2^{13} - 1 = 8191$ is prime.

Solution. If $k = ab$ with $1 < a < k$, then $2^a - 1$ divides $2^{ab} - 1 = (2^a - 1)(2^{a(b-1)} + \cdots + 2^a + 1)$, and $1 < 2^a - 1 < 2^k - 1$. If $q \mid 2^p - 1$, then $2^p \equiv 1 \pmod q$, so $\mathrm{ord}_q(2)$ divides the prime p and is not 1; so it is p, and $p \mid q - 1$ by Lemma 10.3.2. As q is odd, $q \equiv 1 \pmod{2p}$. For $p = 11$ the candidates are $23, 67, 89, \ldots$, and $2047 = 23 \cdot 89$. For $p = 13$ the candidates are the primes $q \equiv 1 \pmod{26}$ with $q \leq \sqrt{8191} < 91$, namely 53 and 79; neither divides 8191 ($8191 = 154 \cdot 53 + 29 = 103 \cdot 79 + 54$), so 8191 is prime. □

Exercise 10.9.11. Let $n = pq$ with $p \neq q$ prime. Show that p and q can be computed from n and $\varphi(n)$, as the roots of a quadratic equation. Find p and q for $n = 2021$ and $\varphi(n) = 1932$.

Solution. $\varphi(n) = (p-1)(q-1) = n - (p+q) + 1$ gives $p + q = n + 1 - \varphi(n)$, and $pq = n$; so p and q are the roots of $X^2 - (n + 1 - \varphi(n))X + n$. For $n = 2021$: $p + q = 90$ and $pq = 2021$, so $X^2 - 90X + 2021 = (X - 43)(X - 47)$, and $2021 = 43 \cdot 47$. □

Exercise 10.9.12. Show that $\sum_{d|n} \mu(d)\tau(n/d) = 1$ and $\sum_{d|n} \mu(d)\sigma(n/d) = n$ for all n, and that $\sum_{d|n} |\mu(d)| = 2^r$ if n has r distinct prime factors.

Solution. $\mu * \tau = \mu * \mathbf{1} * \mathbf{1} = \varepsilon * \mathbf{1} = \mathbf{1}$ and $\mu * \sigma = \mu * \mathbf{1} * \mathrm{N} = \mathrm{N}$, by Propositions 10.6.2 and 10.6.3. The function $|\mu| * \mathbf{1}$ is multiplicative and takes the value $1 + 1 = 2$ at every prime power p^k, $k \geq 1$; so its value at n is 2^r. □

Exercise 10.9.13. Factor $11+7i$ into Gaussian primes, and list all representations of 65 as a sum of two squares, checking the count against Theorem 10.7.3.

Solution. $N(11+7i) = 170 = 2\cdot 5\cdot 17$. Dividing by $1+i$: $(11+7i)(1-i)/2 = 9-2i$, of norm 85. Of the primes $2\pm i$ of norm 5, $2-i$ divides: $(9-2i)(2+i)/5 = 4+i$, of norm 17. So $11+7i = (1+i)(2-i)(4+i)$. For $65 = 5\cdot 13$, $r_2(65) = 4(d_1-d_3) = 4\cdot 4 = 16$, the divisors $1,5,13,65$ all being $\equiv 1 \pmod 4$; the representations are $(\pm1,\pm8)$, $(\pm8,\pm1)$, $(\pm4,\pm7)$, $(\pm7,\pm4)$, coming from $65 = 1+64 = 16+49$. □

Exercise 10.9.14. Show that $\mathbb{Z}[\sqrt{-2}]$ is a Euclidean domain for $N(a+b\sqrt{-2}) = a^2+2b^2$, and deduce again that an odd prime p is of the form x^2+2y^2 if and only if $p \equiv 1,3 \pmod 8$. Show that $\mathbb{Z}[\sqrt{-3}]$ is not a UFD.

Solution. For $a/b = u+v\sqrt{-2}$ choose integers m,n with $|u-m|, |v-n| \le \frac12$; then $N(a/b - (m+n\sqrt{-2})) \le \frac14+\frac24 < 1$. If $(\frac{-2}{p}) = 1$, which by Corollary 10.4.3 and Proposition 10.4.7 means $p \equiv 1,3 \pmod 8$, then $p \mid x^2+2 = (x+\sqrt{-2})(x-\sqrt{-2})$ without dividing either factor, so p is not prime in the UFD $\mathbb{Z}[\sqrt{-2}]$ and $p = N(\pi) = a^2+2b^2$ as in Theorem 10.5.1. Conversely, if $p = x^2+2y^2$ then $p \nmid y$ and $(xy^{-1})^2 \equiv -2 \pmod p$. In $\mathbb{Z}[\sqrt{-3}]$, $4 = 2\cdot 2 = (1+\sqrt{-3})(1-\sqrt{-3})$; all these factors have norm 4, no element has norm 2 ($a^2+3b^2 \neq 2$), so they are irreducible, and 2 is not associate to $1\pm\sqrt{-3}$ since the only units are ±1. (In the larger ring $\mathbb{Z}[\omega] \ni \frac{1+\sqrt{-3}}{2}$ the factorisations agree: $1+\sqrt{-3} = 2(1+\omega)$, and $1+\omega$ is a unit.) □

Exercise 10.9.15. Show that an odd prime $p \neq 5$ of the form x^2+5y^2 is $\equiv 1,9 \pmod{20}$, and one of the form $2x^2+2xy+3y^2$ is $\equiv 3,7 \pmod{20}$. Using Lemma 10.8.5, Example 10.8.4(3) and quadratic reciprocity, conclude that $p = x^2+5y^2$ if and only if $p \equiv 1,9 \pmod{20}$.

Solution. If $p = x^2+5y^2$, then $p \equiv x^2 \equiv \pm1 \pmod 5$, and since p is odd exactly one of x, y is odd, so $p \equiv x^2+y^2 \equiv 1 \pmod 4$; hence $p \equiv 1,9 \pmod{20}$. If $p = 2x^2+2xy+3y^2$, then $2p = (2x+y)^2+5y^2 \equiv (2x+y)^2 \pmod 5$, so $2p \equiv \pm1$ and $p \equiv \pm2 \pmod 5$; and y is odd (else p is even), so one of x, $x+y$ is even and $p = 2x(x+y)+3y^2 \equiv 3 \pmod 4$; hence $p \equiv 3,7 \pmod{20}$. Now if $p \equiv 1,9 \pmod{20}$, then $(\frac{-5}{p}) = (\frac{-1}{p})(\frac{p}{5}) = 1\cdot 1$, so -20 is a square modulo $4p$ (as in the proof of Corollary 10.8.6), and p is represented by one of the two reduced forms of discriminant -20; by the congruences it is not the second. □

Exercise 10.9.16. Find all reduced forms of discriminants -15, -24 and -56, and check that $h(-15) = 2$, $h(-24) = 2$ and $h(-56) = 4$.

Solution. $D=-15$: $a \le 2$, b odd; $b = \pm1$, $ac = 4$: $(1,1,4)$ and $(2,1,2)$ (for $a = c = 2$ only $b \ge 0$ is allowed). $D=-24$: $a \le 2$, b even; $b = 0$, $ac = 6$: $(1,0,6)$ and $(2,0,3)$; $b = \pm2$ would need $a = 2$ and $c = 28/8$. $D=-56$: $a \le 4$, b even; $b = 0$, $ac = 14$: $(1,0,14)$, $(2,0,7)$; $b = \pm2$, $ac = 15$, $a \ge 2$: $(3,\pm2,5)$; $b = \pm4$, $ac = 18$, $a = 4$: no. So the reduced forms are $(1,0,14)$, $(2,0,7)$, $(3,2,5)$, $(3,-2,5)$. □

Exercise 10.9.17. Verify condition (1) of Theorem 10.8.7 for $p = 11$ and $p = 17$, so that n^2+n+11 and n^2+n+17 are prime for $0 \le n \le 9$ and $0 \le n \le 15$. Show that n^2+n+13 is not always prime for $0 \le n \le 11$ and find the corresponding non-principal reduced form of discriminant -51.

Solution. $p = 11$, $D = -43$: $a \le \sqrt{43/3} < 4$, $b \in \{\pm1,\pm3\}$, $ac = 11$ or 13, both prime, so $a = 1$ and the form is $(1,1,11)$. $p = 17$, $D = -67$: $a < 5$, $b \in \{\pm1,\pm3\}$, $ac = 17$ or 19, prime, so only $(1,1,17)$. For $p = 13$: $1+1+13 = 15 = 3\cdot 5$; correspondingly $D = -51$ has the reduced form $(3,3,5)$ (with $b = 3$, $ac = (9+51)/4 = 15$). □

Exercise 10.9.18. Let f be a positive definite form. Show that $f(x, y) = f(-x, -y)$, so that every number represented by f is represented an even number of times; and show that $x^2 + y^2$ represents n properly if and only if n is not divisible by 4 nor by any prime $q \equiv 3 \pmod 4$.

Solution. The first statement is clear. By Lemma 10.8.5 and $h(-4) = 1$, n is properly represented by $x^2 + y^2$ if and only if $-4 \equiv b^2 \pmod{4n}$ for some b, that is, $b = 2b'$ with $b'^2 \equiv -1 \pmod n$. This congruence is solvable modulo $q \equiv 3 \pmod 4$ never, modulo 4 never, modulo 2 always, and modulo powers p^k of primes $p \equiv 1 \pmod 4$ always: the unit group U_{p^k} is cyclic of order $p^{k-1}(p-1)$ (Theorem 10.3.7), which is divisible by 4, so it has an element x of order 4, and x^2 is the unique element of order 2, namely -1. By the Chinese remainder theorem (Theorem 10.2.6) it is solvable modulo n exactly under the stated condition. □

Chapter 11

Linear Algebra

11.1 Introduction

This chapter develops linear algebra over a field: linear maps and matrices, duality, determinants, linear systems (Gaussian elimination, the Rouché–Capelli theorem, Cramer's rule, and the computation of the rank by minors with Kronecker's bordered minors theorem), eigenvalues and canonical forms, bilinear forms, inner product spaces and the spectral theorem, and complex structures on real vector spaces, with the "two out of three" property of compatible inner products, symplectic forms and complex structures. The last topic is the linear algebra underlying Hodge theory: the decomposition $V_{\mathbb{C}} = V^{1,0} \oplus V^{0,1}$ of a real vector space with a complex structure is the pointwise version of the decomposition of forms on a complex manifold (Chapter 44) and of the Hodge decomposition (Chapter 48).

Bases and dimension were introduced in Section 8.8. References are [Hal74], [Axl15] and [Lan02, Chapters XIII–XV].

Prerequisites. Chapter 7 (Groups), Chapter 8 (Rings and Modules) and Chapter 9 (Fields and Galois Theory).

On the way to the Hodge conjecture. Needed: dimension, matrices, duality, determinants, eigenvalues, inner product spaces and the spectral theorem, and above all complex structures (Section 11.11), which are the linear algebra behind the Hodge decomposition. Gaussian elimination and canonical forms are background.

Throughout, k is a field and vector spaces are k-vector spaces, unless stated otherwise.

11.2 Linear maps and dimension

Definition 11.2.1. A *vector space* over a field k is a set V with an addition $V \times V \to V$, $(v, w) \mapsto v + w$, making V an abelian group with neutral element 0, and a scalar multiplication $k \times V \to V$, $(a, v) \mapsto av$, such that $a(v + w) = av + aw$, $(a + b)v = av + bv$, $(ab)v = a(bv)$ and $1v = v$; that is, a module over the ring k (Chapter 8). A *linear map* is a homomorphism of modules: $f(v + w) = f(v) + f(w)$ and $f(av) = af(v)$. A *subspace* is a subset containing 0 and closed under addition and scalar multiplication.

From the axioms, $0v = 0$ (as $0v = (0 + 0)v = 0v + 0v$), $a0 = 0$, and $(-1)v = -v$. Bases and dimension are those of free modules (Section 8.8): every vector space has a basis, and all bases have the same cardinality, the dimension.

Example 11.2.2.

1. k^n, with the standard basis $e_1, \dots, e_n$; the matrices $M_{m\times n}(k)$, of dimension mn.

2. *Polynomials.* The polynomial ring $k[x]$ (Definition 8.6.1) is a vector space under addition of polynomials and multiplication by constants, and the monomials $1, x, x^2, \ldots$ form a basis. This is Lemma 8.6.2 in the language of linear algebra. A polynomial *is* the sequence of its coefficients, x^i is the sequence with 1 in position i and 0 elsewhere, and a constant c multiplies a sequence termwise, $c(a_0, a_1, \ldots) = (ca_0, ca_1, \ldots)$; hence $\sum_{i=0}^{n} a_i x^i = (a_0, \ldots, a_n, 0, 0, \ldots)$. The monomials *span*: a polynomial has only finitely many nonzero coefficients $a_0, \ldots, a_n$, and it equals the finite combination $\sum_{i=0}^{n} a_i x^i$. They are *linearly independent*: if a finite combination $\sum_{i=0}^{n} a_i x^i$ is the zero polynomial, then the sequence $(a_0, \ldots, a_n, 0, \ldots)$ is zero, so every $a_i = 0$. In other words, $k[x]$ is the space $k^{(\mathbb{N})}$ of finitely supported sequences of the next item, and the monomials are its standard basis vectors e_n. Its dimension is infinite and countable, the basis being indexed by $\mathbb{N}$.

   The polynomials of degree at most d, together with 0, form a subspace $k[x]_{\le d}$, as the coefficients of $f + g$ and cf in degrees above d vanish when those of f and g do. The same argument shows that $1, x, \ldots, x^d$ is a basis of it, so $\dim k[x]_{\le d} = d + 1$. Here is a second basis. For distinct $a_0, \ldots, a_d \in k$, the *Lagrange polynomials*

$$L_i = \prod_{j \neq i} \frac{x - a_j}{a_i - a_j}, \qquad i = 0, \ldots, d,$$

   have degree d and satisfy $L_i(a_l) = 1$ if $l = i$ and $L_i(a_l) = 0$ if $l \neq i$: for $l \neq i$ the factor with $j = l$ vanishes at a_l, and at a_i every factor equals 1. They are independent: evaluating $\sum_i c_i L_i = 0$ at a_l gives $c_l = 0$. They span: for $p \in k[x]_{\le d}$, the polynomial $q = p - \sum_i p(a_i) L_i$ lies in $k[x]_{\le d}$ and vanishes at the $d + 1$ points $a_0, \ldots, a_d$, so $q = 0$, as a nonzero polynomial of degree at most d has at most d roots (Corollary 8.6.7). So $p = \sum_i p(a_i) L_i$: the coordinates of p in this basis are its values $p(a_i)$. Equivalently (*Lagrange interpolation*), for any $b_0, \ldots, b_d \in k$ there is exactly one polynomial of degree at most d with $p(a_i) = b_i$ for all i, namely $\sum_i b_i L_i$. For instance, through the points $(0, 1)$, $(1, 3)$, $(2, 7)$ passes exactly one polynomial of degree at most 2, namely $\frac{1}{2}(x-1)(x-2) - 3x(x-2) + \frac{7}{2}x(x-1) = x^2 + x + 1$.

3. *Function spaces.* For a set S, the functions $S \to k$ form a vector space k^S under pointwise operations; for S finite it is $k^{|S|}$, and for S infinite it has infinite dimension, since the indicator functions of points are independent. The continuous functions $C([0, 1])$ form an infinite-dimensional real vector space: the monomials x^n are linearly independent, since a nonzero polynomial has finitely many roots. So do the sequences $k^{\mathbb{N}}$, which contain the subspace $k^{(\mathbb{N})}$ of finitely supported sequences, with basis the e_n; a basis of $k^{\mathbb{N}}$ itself exists by Zorn's lemma but cannot be written down.

4. $\mathbb{R}$ is a vector space over $\mathbb{Q}$ of uncountable dimension, since a countable-dimensional $\mathbb{Q}$-vector space is countable; $\mathbb{C}$ is a real vector space of dimension 2, with basis $1, i$.

5. The solutions of a homogeneous linear system $Ax = 0$, or of a homogeneous linear differential equation $y'' + y = 0$ (basis cos, sin), form vector spaces; the solutions of $Ax = b$ with $b \neq 0$ do not, as they do not contain 0.

Subspaces behave well under linear maps. The following facts are used constantly, usually without comment.

Lemma 11.2.3. *Let $f : V \to W$ be a linear map.*

1. *If $U \subseteq V$ is a subspace, its image $f(U) = \{f(u) : u \in U\}$ is a subspace of W. In particular the image* $\operatorname{im} f = f(V)$ *is a subspace.*

2. *If $U' \subseteq W$ is a subspace, its preimage $f^{-1}(U') = \{v \in V : f(v) \in U'\}$ is a subspace of V containing* $\ker f = f^{-1}(0)$.

3. *f maps the span of a set $S \subseteq V$ onto the span of $f(S)$. Hence* $\dim f(U) \leq \dim U$*; if f is injective, it maps linearly independent sets to linearly independent sets and* $\dim f(U) = \dim U$.

4. *Intersections of subspaces are subspaces, and $U_1 + U_2 = \{u_1 + u_2 : u_i \in U_i\}$ is the smallest subspace containing the subspaces U_1 and U_2. A union $U_1 \cup U_2$ is a subspace only if $U_1 \subseteq U_2$ or $U_2 \subseteq U_1$.*

Proof. (1) $0 = f(0) \in f(U)$; and $f(u_1)+f(u_2) = f(u_1+u_2)$ and $af(u) = f(au)$ lie in $f(U)$, since $u_1 + u_2, au \in U$. (2) $f(0) = 0 \in U'$; if $f(v_1), f(v_2) \in U'$, then $f(v_1 + v_2) = f(v_1) + f(v_2) \in U'$ and $f(av_1) = af(v_1) \in U'$. Since $0 \in U'$, $\ker f \subseteq f^{-1}(U')$. (3) $f(\sum a_i s_i) = \sum a_i f(s_i)$, so f maps the combinations of elements of S exactly onto the combinations of elements of $f(S)$. A basis B of U spans U, so $f(B)$ spans $f(U)$, and $f(U)$ has a basis contained in $f(B)$ (Theorem 8.8.4), of cardinality at most $|B|$. If f is injective and $\sum a_i f(s_i) = 0$ for distinct $s_i \in S$, then $f(\sum a_i s_i) = 0$, so $\sum a_i s_i = 0$; if S is independent, all $a_i = 0$. Then $f(B)$ is a basis of $f(U)$, of the same cardinality as B. (4) The conditions defining a subspace are preserved by intersections. $U_1 + U_2$ is the image of the linear map $U_1 \times U_2 \to V$, $(u_1, u_2) \mapsto u_1 + u_2$, so a subspace by (1), and every subspace containing U_1 and U_2 contains all sums $u_1 + u_2$. If neither U_i contains the other, pick $u_1 \in U_1 \setminus U_2$ and $u_2 \in U_2 \setminus U_1$. Then $u_1 + u_2 \notin U_1$, since otherwise $u_2 = (u_1 + u_2) - u_1 \in U_1$, and similarly $u_1 + u_2 \notin U_2$; so $U_1 \cup U_2$ is not closed under addition. □

Example 11.2.4. Let $f : \mathbb{R}^3 \to \mathbb{R}^2$, $f(x, y, z) = (x + z, y)$. The plane $U = \{z = 0\}$ is mapped onto all of $\mathbb{R}^2$, and the line $L = \mathbb{R}(1, 0, -1)$ to 0: it is $\ker f$. The preimage of the line $\mathbb{R}(1, 0)$ is $\{y = 0\}$, a plane containing $\ker f$. Images of intersections can be smaller than intersections of images: for $U_1 = \mathbb{R}(1, 0, 0)$ and $U_2 = \mathbb{R}(0, 0, 1)$, $U_1 \cap U_2 = 0$, but $f(U_1) = f(U_2) = \mathbb{R}(1, 0)$. The coordinate axes of $\mathbb{R}^2$ are subspaces whose union is not: $(1, 0) + (0, 1) = (1, 1)$ lies on neither axis.

Proposition 11.2.5. *Let V be a vector space and $W \subseteq V$ a subspace.*

1. *W has a* complement*: a subspace U with $V = W \oplus U$ (that is, $W + U = V$ and $W \cap U = 0$). Then $U \cong V/W$ and* $\dim V = \dim W + \dim V/W$.

2. $\dim W \leq \dim V$*, and if* $\dim V$ *is finite and* $\dim W = \dim V$ *then $W = V$.*

3. *If $U, W \subseteq V$ are finite-dimensional,* $\dim(U + W) + \dim(U \cap W) = \dim U + \dim W$.

Proof. (1) Extend a basis B_W of W to a basis B of V (Theorem 8.8.4) and let U be spanned by $B \setminus B_W$. The projection $V \to V/W$ restricts to an isomorphism $U \to V/W$, and $B = B_W \sqcup (B \setminus B_W)$ gives the formula (as cardinals). (2) The first claim follows from (1). If $\dim W = \dim V < \infty$, a basis of W has $\dim V$ elements and extends to a basis of V, which by Theorem 8.8.5 has no further elements. (3) Extend a basis of $U \cap W$ to bases of U and of W; the union of these bases is a basis of $U + W$. □

Theorem 11.2.6 (Rank–nullity)**.** *For a linear map $f : V \to W$, $V/\ker f \cong \operatorname{im} f$, so* $\dim V = \dim \ker f + \dim \operatorname{im} f$*. If* $\dim V = \dim W < \infty$*, then f is injective if and only if it is surjective.*

Proof. The isomorphism is the first isomorphism theorem (Proposition 8.7.3); combine with Proposition 11.2.5(1). If $\dim V = \dim W = n$, then f is injective iff $\dim \operatorname{im} f = n$ iff $\operatorname{im} f = W$ by Proposition 11.2.5(2). □

Counterexample 11.2.7. The last statement fails in infinite dimension. On $V = k^{(\mathbb{N})}$ the *shift* $e_n \mapsto e_{n+1}$ is injective but not surjective, and $e_0 \mapsto 0$, $e_{n+1} \mapsto e_n$ is surjective but not injective.

11.3 Matrices

Definition 11.3.1. Let V and W have ordered bases $\mathcal{B} = (v_1, \dots, v_n)$ and $C = (w_1, \dots, w_m)$. The *matrix* of a linear map $f : V \to W$ is the $m \times n$ matrix $[f]_{C,\mathcal{B}} = (a_{ij})$ with $f(v_j) = \sum_i a_{ij} w_i$: its j-th column contains the coordinates of $f(v_j)$.

Example 11.3.2. 1. *Differentiation.* On the space $k[x]_{\le 3}$ of polynomials of degree at most 3, with basis $(1, x, x^2, x^3)$, the derivative D sends $1 \mapsto 0$, $x \mapsto 1$, $x^2 \mapsto 2x$, $x^3 \mapsto 3x^2$; writing the coordinates of these images as columns,

$$[D] = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Since the fourth derivative of a cubic is zero, $[D]^4 = 0$, as one checks by multiplying.

2. *Projection and reflection in* $\mathbb{R}^2$. The orthogonal projection onto the line spanned by $(1,1)$ sends $e_1 \mapsto \frac{1}{2}(1,1)$ and $e_2 \mapsto \frac{1}{2}(1,1)$, so its matrix is $\frac{1}{2}\left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$; the reflection in the same line exchanges e_1 and e_2, with matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. In the basis $(1,1)$, $(1,-1)$ adapted to the line the two matrices become $\operatorname{diag}(1,0)$ and $\operatorname{diag}(1,-1)$: a good basis makes the matrix simple, which is the theme of the rest of the chapter.

3. *Rotations.* With the trigonometric functions (Chapter 27), the rotation of $\mathbb{R}^2$ by the angle θ has matrix $R_\theta = \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$, its columns being the images of e_1 and e_2. Composition corresponds to multiplication, and $R_\alpha R_\beta = R_{\alpha+\beta}$, read entry by entry, is the pair of addition formulas for $\cos(\alpha+\beta)$ and $\sin(\alpha+\beta)$.

Proposition 11.3.3. *The map $f \mapsto [f]_{C,\mathcal{B}}$ is an isomorphism of vector spaces $\operatorname{Hom}_k(V,W) \to M_{m\times n}(k)$, so $\dim \operatorname{Hom}_k(V,W) = mn$. Composition corresponds to matrix multiplication: $[g \circ f]_{\mathcal{D},\mathcal{B}} = [g]_{\mathcal{D},C}[f]_{C,\mathcal{B}}$. If $\mathcal{B}', C'$ are other bases and $P = [\mathrm{id}]_{\mathcal{B},\mathcal{B}'}$, $Q = [\mathrm{id}]_{C,C'}$, then $[f]_{C',\mathcal{B}'} = Q^{-1}[f]_{C,\mathcal{B}}P$. In particular the matrices of an endomorphism in different bases are* similar*: $A' = P^{-1}AP$.*

Proof. A linear map is determined by the images of a basis, which can be arbitrary (Proposition 8.7.5); this gives bijectivity, and linearity is clear. If $f(v_j) = \sum_i a_{ij} w_i$ and $g(w_i) = \sum_l b_{li} u_l$, then $g(f(v_j)) = \sum_l (\sum_i b_{li} a_{ij}) u_l$. The change of basis formula follows by writing $f = \mathrm{id}_W \circ f \circ \mathrm{id}_V$ and using that $[\mathrm{id}]_{C',C} = Q^{-1}$. □

Remark 11.3.4. *Change of basis, change of coordinates, change of variables.* Let $\mathcal{B} = (v_1, \dots, v_n)$ and $\mathcal{B}' = (v'_1, \dots, v'_n)$ be bases of V, and $P = [\mathrm{id}]_{\mathcal{B},\mathcal{B}'}$, whose j-th column contains the coordinates of v'_j in $\mathcal{B}$: $v'_j = \sum_i p_{ij} v_i$. If a vector v has coordinate columns x in $\mathcal{B}$ and x' in $\mathcal{B}'$, then

$$x = Px', \qquad x' = P^{-1}x,$$

since $v = \sum_j x'_j v'_j = \sum_i (\sum_j p_{ij} x'_j) v_i$. So the basis vectors change with P and the coordinates with P^{-1}, the "contravariant" behaviour of coordinates. This is a *passive* transformation: the vector stays where it is and only its description changes. An *active* transformation moves the vectors, for instance by the linear map f with $f(v_j) = v'_j$, whose matrix in $\mathcal{B}$ is P; it sends the vector with coordinates x to the vector with coordinates Px. The passive change by P and the active transformation by P act on coordinate columns by inverse matrices.

In linear algebra, a *change of variables* is the substitution $x = Px'$ in a formula, which is the same operation read from the side of the formula; the result depends on what kind of object the formula describes:

1. coordinates of vectors: $x' = P^{-1}x$;
2. linear forms $\varphi(v) = ax$, with a a row: $a' = aP$;
3. endomorphisms, $y = Ax$: $A' = P^{-1}AP$ (*similarity*, Proposition 11.3.3);
4. bilinear forms $B(v, w) = x^T Gy$, with Gram matrix G (Section 11.9): $G' = P^T GP$ (*congruence*); for a quadratic form $q(x) = x^T Gx$ this is the familiar substitution.

The rules (3) and (4) agree exactly when $P^{-1} = P^T$, that is, when P is orthogonal; this is why the spectral theorem (Theorem 11.10.6), which diagonalises a real symmetric matrix by an orthogonal P, diagonalises it as an endomorphism and as a quadratic form at the same time. In general the invariants differ: similar matrices have the same eigenvalues, congruent symmetric real matrices the same signature (Theorem 11.9.5) but not the same eigenvalues, as $\operatorname{diag}(1, 4)$ and $I = P^T \operatorname{diag}(1, 4)P$ with $P = \operatorname{diag}(1, \frac{1}{2})$ show.

Outside linear algebra, a change of variables is a substitution $x = \varphi(y)$ with φ a diffeomorphism, as in integrals, where the factor $|\det D\varphi|$ appears (Chapter 28), and a change of coordinates on a manifold is a transition map between charts (Chapter 33). Their derivatives at a point are linear changes of coordinates as above: components of tangent vectors transform like coordinates of vectors, with the Jacobian matrix in the role of P^{-1}, and differentials of functions like linear forms.

Definition 11.3.5. The *rank* of a linear map is $\dim \operatorname{im} f$. The *column rank* of a matrix $A \in M_{m\times n}(k)$ is the dimension of the span of its columns in k^m, that is, the rank of the map $k^n \to k^m$ it defines, and its *row rank* is the column rank of the transpose A^T.

11.4 Duality

Definition 11.4.1. The *dual* of V is $V^* = \operatorname{Hom}_k(V, k)$. For $f\colon V \to W$, the *transpose* is $f^*\colon W^* \to V^*$, $\varphi \mapsto \varphi \circ f$. For a subspace $W \subseteq V$, the *annihilator* is $W^\perp = \{\varphi \in V^* : \varphi|_W = 0\}$. If $(v_1, \dots, v_n)$ is a basis of V, the *dual basis* $(v_1^*, \dots, v_n^*)$ is given by $v_i^*(v_j) = \delta_{ij}$.

Proposition 11.4.2. *Let V, W be finite-dimensional.*

1. *The dual basis is a basis of V^*; so* $\dim V^* = \dim V$.
2. *The map* $\operatorname{ev}\colon V \to V^{**}$ *of Example 6.5.5 is an isomorphism.*
3. *In dual bases, the matrix of f^* is the transpose of the matrix of f.*
4. $\dim W^\perp = \dim V - \dim W$ *for $W \subseteq V$, and* $(\operatorname{im} f)^\perp = \ker f^*$.
5. $\operatorname{rank} f^* = \operatorname{rank} f$. *Hence row rank equals column rank for every matrix.*

Proof. (1) $\varphi = \sum_i \varphi(v_i)v_i^*$ for $\varphi \in V^*$, and the coefficients are determined by evaluating on the v_j. (2) ev is injective: if $v \neq 0$, extend v to a basis and take the corresponding dual basis element. Both sides have dimension n; apply Theorem 11.2.6. (3) If $f(v_j) = \sum_i a_{ij}w_i$ then $f^*(w_i^*)(v_j) = a_{ij}$, so $f^*(w_i^*) = \sum_j a_{ij}v_j^*$. (4) Extend a basis $v_1, \dots, v_r$ of W to a basis of V; then $W^\perp$ has basis $v_{r+1}^*, \dots, v_n^*$. And $\varphi \in \ker f^*$ iff $\varphi \circ f = 0$ iff φ vanishes on $\operatorname{im} f$. (5) By (4) and rank–nullity for f^*, $\operatorname{rank} f^* = \dim W - \dim \ker f^* = \dim W - \dim(\operatorname{im} f)^\perp = \dim \operatorname{im} f$. Apply (3). □

Counterexample 11.4.3. In infinite dimension $\operatorname{ev}\colon V \to V^{**}$ is injective (by the same argument) but not surjective. Let $k = \mathbb{Q}$ and $V = \mathbb{Q}^{(\mathbb{N})}$, which is countable. Then $V^* \cong \mathbb{Q}^{\mathbb{N}}$, which is uncountable (it contains the sequences with values in $\{0, 1\}$). Choosing a basis of V^* gives an injection $V^* \to V^{**}$ (send the basis to its dual family), so V^{**} is uncountable, and cannot be the image of the countable set V.

11.5 Determinants

In this section R is a commutative ring. For $A \in M_n(R)$ we write $A = (a_1|\cdots|a_n)$ with columns $a_j \in R^n$.

Definition 11.5.1. A map $D\colon (R^n)^n \to R$ is *multilinear* if it is R-linear in each argument, and *alternating* if $D(a_1,\dots,a_n) = 0$ whenever $a_i = a_j$ for some $i \neq j$. The *determinant* of $A \in M_n(R)$ is

$$\det A = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma)\, a_{\sigma(1)1} a_{\sigma(2)2} \cdots a_{\sigma(n)n},$$

where sgn is the sign of Proposition 7.8.3.

Theorem 11.5.2. *The determinant, as a function of the columns, is multilinear and alternating with* $\det I = 1$. *Every multilinear alternating* $D\colon (R^n)^n \to R$ *satisfies* $D(a_1,\dots,a_n) = \det(a_1|\cdots|a_n)\cdot D(e_1,\dots,e_n)$.

Proof. Multilinearity is clear, and $\det I = 1$ since only $\sigma = \mathrm{id}$ contributes. If $a_i = a_j$ with $i \neq j$, let $\tau = (i\ j)$. The map $\sigma \mapsto \sigma\tau$ is a bijection from even to odd permutations, and the terms for σ and $\sigma\tau$ have the same product of entries (as columns i and j agree) and opposite signs; so the sum vanishes.

Let D be multilinear and alternating. First, D changes sign when two arguments are exchanged: expand $0 = D(\dots, a+b, \dots, a+b, \dots)$. Hence $D(e_{\sigma(1)},\dots,e_{\sigma(n)}) = \operatorname{sgn}(\sigma) D(e_1,\dots,e_n)$ for $\sigma \in S_n$, writing σ as a product of transpositions. Writing $a_j = \sum_i a_{ij} e_i$ and expanding by multilinearity, $D(a_1,\dots,a_n) = \sum_\phi a_{\phi(1)1}\cdots a_{\phi(n)n} D(e_{\phi(1)},\dots,e_{\phi(n)})$ over all maps $\phi\colon \{1,\dots,n\} \to \{1,\dots,n\}$. The terms with ϕ not injective vanish, and the others give $\det(a_1|\cdots|a_n) D(e_1,\dots,e_n)$. □

Proposition 11.5.3. *For* $A, B \in M_n(R)$*:*

1. $\det(AB) = \det A \det B$*;*
2. $\det A^T = \det A$*, so* det *is also multilinear and alternating in the rows;*
3. *(Laplace expansion) for each* j, $\det A = \sum_i (-1)^{i+j} a_{ij} \det A_{ij}$*, where* A_{ij} *is obtained by deleting row* i *and column* j*;*
4. *the* adjugate $\operatorname{adj} A$*, with* (i,j) *entry* $(-1)^{i+j} \det A_{ji}$*, satisfies* $A \operatorname{adj} A = \operatorname{adj} A\, A = \det(A) I$*;*
5. A *is invertible in* $M_n(R)$ *if and only if* $\det A \in R^\times$.

Proof. (1) The map $(b_1,\dots,b_n) \mapsto \det(Ab_1|\cdots|Ab_n)$ is multilinear and alternating, with value $\det A$ on $(e_1,\dots,e_n)$; apply Theorem 11.5.2. (2) Reindex the sum by $\sigma \mapsto \sigma^{-1}$, using $\operatorname{sgn}(\sigma^{-1}) = \operatorname{sgn}(\sigma)$. (3) Both sides are multilinear and alternating in the columns other than j, and linear in column j. Writing $a_j = \sum_i a_{ij} e_i$, it suffices to treat $a_j = e_i$. Moving row i to the top and column j to the front by $i-1$ and $j-1$ adjacent exchanges changes the determinant by $(-1)^{i+j}$ and gives a matrix with first column e_1, whose determinant is $\det A_{ij}$ by the Leibniz formula (only permutations fixing 1 contribute). (4) The (j,j') entry of $\operatorname{adj}(A)A$ is $\sum_i (-1)^{i+j} \det A_{ij} a_{ij'}$, which by (3) is the determinant of A with column j replaced by column j': this is $\det A$ if $j = j'$ and 0 otherwise. The other product is handled with (2). (5) If $AB = I$ then $\det A \det B = 1$. Conversely $(\det A)^{-1} \operatorname{adj} A$ is an inverse by (4). □

Example 11.5.4. 1. *A* 3×3 *determinant.* For $A = \left(\begin{smallmatrix} 2 & 1 & 3 \\ 0 & -1 & 4 \\ 1 & 2 & 0 \end{smallmatrix}\right)$, the Laplace expansion along the first column has two nonzero terms: $\det A = 2\det\left(\begin{smallmatrix} -1 & 4 \\ 2 & 0 \end{smallmatrix}\right) + (-1)^{3+1}\cdot 1 \cdot \det\left(\begin{smallmatrix} 1 & 3 \\ -1 & 4 \end{smallmatrix}\right) = 2(-8) + 7 = -9$. Alternatively, subtracting $\frac{1}{2}$ of the first row from the third (which does

not change the determinant, by multilinearity and the alternating property in the rows) gives the row $(0, \frac{3}{2}, -\frac{3}{2})$, and then adding $\frac{3}{2}$ times the second row gives $(0, 0, \frac{9}{2})$; the matrix is now upper triangular, and $\det A = 2 \cdot (-1) \cdot \frac{9}{2} = -9$.

2. *Triangular matrices.* The determinant of an upper triangular matrix is the product of its diagonal entries. In the Leibniz formula, a permutation with $\sigma(j) \le j$ for all j is the identity ($\sigma(1) = 1$, then $\sigma(2) = 2$, and so on); so every $\sigma \neq \mathrm{id}$ has some j with $\sigma(j) > j$, and its term contains the entry $a_{\sigma(j)j}$, whose row index exceeds its column index: an entry below the diagonal, which is zero.

3. *The Vandermonde determinant.* For $x_1, \dots, x_n \in R$,

$$\det \begin{pmatrix} 1 & x_1 & \cdots & x_1^{n-1} \\ \vdots & & & \vdots \\ 1 & x_n & \cdots & x_n^{n-1} \end{pmatrix} = \prod_{i<j} (x_j - x_i).$$

   By induction on n: subtract x_1 times column $j-1$ from column j, for $j = n, n-1, \dots, 2$ in this order. Row i becomes $(1, x_i - x_1, x_i(x_i - x_1), \dots, x_i^{n-2}(x_i - x_1))$, and the first row becomes $(1, 0, \dots, 0)$. Expanding along the first row and taking the factor $x_i - x_1$ out of row i for $i \ge 2$ leaves $\prod_{i \ge 2}(x_i - x_1)$ times the Vandermonde determinant of $x_2, \dots, x_n$. Over a field it is nonzero exactly when the x_i are distinct; this is why a polynomial of degree less than n is determined by its values at n distinct points.

4. *Geometric meaning.* Over $\mathbb{R}$, $|\det(a_1 | \cdots | a_n)|$ is the volume of the parallelepiped spanned by the columns (made precise with Lebesgue measure in Chapter 28), and the sign records whether the columns are positively oriented. For $n = 2$, $\det \left(\begin{smallmatrix} a & c \\ b & d \end{smallmatrix}\right) = ad - bc$ is the signed area of the parallelogram spanned by (a, b) and (c, d).

Definition 11.5.5. The determinant of an endomorphism f of a finite-dimensional vector space (or of a finitely generated free module over R) is the determinant of its matrix in any basis; it is well defined since $\det(P^{-1}AP) = \det A$. The group $\mathrm{GL}(V)$ of invertible endomorphisms contains $\mathrm{SL}(V) = \{f : \det f = 1\}$, and $\mathrm{GL}_n(R) = M_n(R)^\times$.

11.6 Linear systems, Gaussian elimination and the rank

A system of m linear equations in n unknowns $x_1, \dots, x_n$,

$$a_{i1}x_1 + \cdots + a_{in}x_n = b_i \qquad (1 \le i \le m),$$

is the single equation $Ax = b$ for the matrix $A = (a_{ij}) \in M_{m \times n}(k)$, the column $b \in k^m$ and the unknown column $x \in k^n$. Its theory is the theory of the linear map $x \mapsto Ax$: the system is solvable if and only if b lies in the image, and the solutions, when they exist, form a translate of the kernel. In practice one needs a procedure that decides solvability, finds the solutions and computes ranks; this is *Gaussian elimination*. For matrices depending on parameters it is often more convenient to compute the rank with determinants of square submatrices, the *minors*, and Kronecker's *bordered minors theorem* reduces the number of minors to be examined. In this section k is a field.

Definition 11.6.1. The *elementary row operations* on a matrix are: (i) exchanging two rows; (ii) multiplying a row by a nonzero scalar c; (iii) adding c times one row to another row, for $c \in k$. The *elementary matrices* are the matrices obtained from the identity matrix I_m by one elementary row operation.

Performing an elementary row operation on $A \in M_{m\times n}(k)$ is the same as multiplying A on the left by the corresponding elementary matrix E: row i of EA is (row i of E) times A, that is, the combination of the rows of A with the coefficients in row i of E. Every elementary matrix is invertible, its inverse being the elementary matrix of the inverse operation (exchange the same rows again; multiply by c^{-1}; add $-c$ times the row). Column operations are defined in the same way and correspond to multiplication on the right.

Lemma 11.6.2. *Let $B = PA$ with $P \in \mathrm{GL}_m(k)$, for instance a product of elementary matrices. Then A and B have the same kernel, the same row space and the same rank, and the columns of A and of B satisfy the same linear relations: $\sum_j x_j a_j = 0$ if and only if $\sum_j x_j b_j = 0$, where a_j and b_j are the j-th columns. In particular, a set of columns of A is linearly independent, or is a basis of the column space, if and only if the columns of B with the same indices are.*

Proof. $Ax = 0$ if and only if $PAx = 0$, since P is invertible; and $\sum_j x_j a_j = Ax$. The rows of B are combinations of the rows of A and, since $A = P^{-1}B$, conversely; so the row spaces agree. The rank is the dimension of the column space, which by rank–nullity (Theorem 11.2.6) is $n - \dim\ker A$. A set S of columns is independent if and only if no nontrivial relation with coefficients supported in S holds, and it is a basis of the column space if moreover every column is a combination of the columns in S, which again is a statement about relations. □

Definition 11.6.3. A matrix is in *row echelon form* if its nonzero rows come before its zero rows and the first nonzero entry of each nonzero row, its *pivot*, lies strictly to the right of the pivot of the row above. It is in *reduced* row echelon form if moreover every pivot is 1 and is the only nonzero entry of its column. The columns containing pivots are the *pivot columns*.

For instance

$$\begin{pmatrix} 1 & 2 & 0 & 1 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

is in reduced row echelon form, with pivots in columns 1 and 3.

Theorem 11.6.4 (Gaussian elimination)**.** *Every $A \in M_{m\times n}(k)$ can be transformed by elementary row operations into a matrix R in reduced row echelon form; so $R = PA$ with P a product of elementary matrices. If R has r nonzero rows, then*

1. $\operatorname{rank} A = r$;
2. *the nonzero rows of R form a basis of the row space of A;*
3. *the columns of A with the indices of the pivot columns of R form a basis of the column space of A.*

Proof. Existence, by induction on the number m of rows. If $A = 0$ there is nothing to do. Otherwise let j be the first column with a nonzero entry. Exchange rows to bring a nonzero entry of column j to row 1, multiply row 1 by the inverse of this entry, and subtract suitable multiples of row 1 from the other rows; now column j is e_1, and the columns before it are zero. Apply the induction hypothesis to the matrix formed by rows $2, \dots, m$; operations on these rows do not change row 1, and keep the first j columns zero in these rows, so the result is in row echelon form with pivots equal to 1. Finally, for each pivot, from the last one to the first, subtract multiples of its row from the rows above to make the other entries of its column zero; this does not change the entries to the left of the pivot in those rows, since the row of the pivot is zero there.

Properties. Let the pivots of R be in columns $j_1 < \cdots < j_r$. Column j_s of R is the standard vector e_s, and every column of R has zeros below row r; so the pivot columns of

R are independent and span the column space of R, which therefore has dimension r. By Lemma 11.6.2, (3) holds and $\operatorname{rank} A = \operatorname{rank} R = r$. The nonzero rows of R are independent, since a combination $\sum_s c_s(\text{row } s)$ has entry c_s in column j_s; they span the row space of R, which is that of A. □

Since the row rank of A is the dimension of its row space, (1) and (2) give another proof that row rank equals column rank (Proposition 11.4.2(5)). The proof is an algorithm, and the reduced row echelon form is unique (Exercise 11.12.8). To compute only the rank, a row echelon form, not necessarily reduced, suffices: its number of nonzero rows is the rank, by the same argument.

Theorem 11.6.5 (Rouché–Capelli)**.** *Let $A \in M_{m\times n}(k)$ and $b \in k^m$. The system $Ax = b$ has a solution if and only if* $\operatorname{rank} A = \operatorname{rank}(A \mid b)$*, where $(A \mid b)$ is the* augmented *matrix obtained by adding the column b. In that case, if x_0 is one solution, the set of all solutions is*

$$x_0 + \ker A = \{x_0 + y : Ay = 0\},$$

an affine subspace of dimension $n - \operatorname{rank} A$.

Proof. $Ax = \sum_j x_j a_j$, so the system is solvable if and only if b lies in the span of the columns of A, that is, if and only if adding b does not enlarge the column space; as the column space of $(A \mid b)$ contains that of A, this happens exactly when the dimensions agree. If $Ax_0 = b$, then $Ax = b$ if and only if $A(x - x_0) = 0$. Finally $\dim \ker A = n - \operatorname{rank} A$ by Theorem 11.2.6. □

To solve a system in practice, bring $(A \mid b)$ to reduced row echelon form $(R \mid c)$; the systems $Ax = b$ and $Rx = c$ have the same solutions, as $(R \mid c) = P(A \mid b)$ with P invertible. If the last column is a pivot column, some row reads $0 = 1$ and there is no solution; this is the case $\operatorname{rank}(A \mid b) > \operatorname{rank} A$. Otherwise the unknowns of the non-pivot columns, the *free variables*, can be chosen arbitrarily, and each equation of $Rx = c$ expresses one pivot unknown in terms of them.

Example 11.6.6. Consider the system

$$\begin{aligned} x_1 + 2x_2 + x_3 &= 1,\\ 2x_1 + 4x_2 \qquad + 2x_4 &= 2,\\ 3x_1 + 6x_2 + x_3 + 2x_4 &= 3. \end{aligned}$$

Subtracting 2 times the first row from the second and 3 times the first row from the third, then the new second row from the third, gives

$$\left(\begin{array}{cccc|c} 1 & 2 & 1 & 0 & 1\\ 2 & 4 & 0 & 2 & 2\\ 3 & 6 & 1 & 2 & 3 \end{array}\right) \to \left(\begin{array}{cccc|c} 1 & 2 & 1 & 0 & 1\\ 0 & 0 & -2 & 2 & 0\\ 0 & 0 & -2 & 2 & 0 \end{array}\right) \to \left(\begin{array}{cccc|c} 1 & 2 & 0 & 1 & 1\\ 0 & 0 & 1 & -1 & 0\\ 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

where the last step multiplies the second row by $-\frac{1}{2}$ and subtracts it from the first. The rank of A and of $(A \mid b)$ is 2, the pivot columns are the first and the third, and the free variables are $x_2 = s$ and $x_4 = t$. The equations $x_1 + 2x_2 + x_4 = 1$ and $x_3 - x_4 = 0$ give the solutions

$$x = (1, 0, 0, 0) + s(-2, 1, 0, 0) + t(-1, 0, 1, 1), \qquad s, t \in k,$$

a plane in k^4, of dimension $4 - 2$. By Theorem 11.6.4(3), the first and third columns of A form a basis of its column space: indeed the second column is twice the first, and the fourth is the first minus the third, as the coefficients in the reduced form show. With right-hand side $(1, 2, 4)$ instead, the same operations produce the row $(0\ 0\ 0\ 0 \mid 1)$, and there is no solution: the third equation contradicts the sum of the first two.

For square systems with invertible matrix the solution has a closed formula in terms of determinants.

Proposition 11.6.7 (Cramer's rule)**.** *Let $A \in M_n(k)$ with $\det A \neq 0$ and $b \in k^n$. The unique solution of $Ax = b$ is given by*

$$x_i = \frac{\det A_i}{\det A} \qquad (1 \leq i \leq n),$$

where A_i is obtained from A by replacing its i-th column with b.

Proof. A is invertible with $A^{-1} = (\det A)^{-1} \operatorname{adj} A$ (Proposition 11.5.3(4)), so $x = A^{-1}b$ is the unique solution and $x_i = (\det A)^{-1} \sum_j (-1)^{i+j} \det(A_{ji})\, b_j$. Since A_i and A agree outside column i, deleting row j and column i from A_i gives A_{ji}, so the sum is the Laplace expansion of $\det A_i$ along its i-th column (Proposition 11.5.3(3)). □

For example, $2x + y = 3$, $x - y = 0$ has $\det A = -3$, $x = \det\left(\begin{smallmatrix} 3 & 1 \\ 0 & -1 \end{smallmatrix}\right)/(-3) = 1$ and $y = \det\left(\begin{smallmatrix} 2 & 3 \\ 1 & 0 \end{smallmatrix}\right)/(-3) = 1$. Cramer's rule is useful in theory, for instance to see that the solution depends rationally on the entries of A and b; for computations with large n, Gaussian elimination, with about n^3 operations, is far cheaper than evaluating $n + 1$ determinants of size n.

11.6.1 Rank and minors

Definition 11.6.8. Let $A \in M_{m\times n}(k)$. For sets $I \subseteq \{1, \ldots, m\}$ and $J \subseteq \{1, \ldots, n\}$ with $|I| = |J| = p$, the $p \times p$ matrix $A_{I,J} = (a_{ij})_{i\in I, j\in J}$, rows and columns in increasing order, is a *submatrix* of A, and $\det A_{I,J}$ is a *minor of order p*. If $M = \det A_{I,J}$, the minors $\det A_{I\cup\{i\},J\cup\{j\}}$ with $i \notin I$ and $j \notin J$ are the minors of order $p + 1$ *bordering* M.

Proposition 11.6.9. *The rank of $A \in M_{m\times n}(k)$ is the largest p such that A has a nonzero minor of order p (and 0 if $A = 0$).*

Proof. If $\det A_{I,J} \neq 0$, the columns of $A_{I,J}$ are independent, and then so are the columns of A with indices in J: a relation among them would restrict, in the rows I, to a relation among the columns of $A_{I,J}$. So $\operatorname{rank} A \geq p$. Conversely, let $r = \operatorname{rank} A$ and choose r independent columns, with index set J. The $m \times r$ matrix they form has column rank r, hence row rank r (Proposition 11.4.2(5)): some r of its rows, with index set I, are independent. Then $A_{I,J}$ is an $r \times r$ matrix of rank r, hence invertible, and $\det A_{I,J} \neq 0$ (Proposition 11.5.3(5)). □

Read literally, the proposition requires checking all minors of order $p + 1$ to show that the rank is at most p; a 4×5 matrix has $\binom{4}{3}\binom{5}{3} = 40$ minors of order 3. The next theorem shows that it suffices to check the minors bordering one nonzero minor of order p: there are $(m - p)(n - p)$ of them, 6 in this example if $p = 2$.

Theorem 11.6.10 (Kronecker's bordered minors theorem)**.** *Let $A \in M_{m\times n}(k)$ and let $M = \det A_{I,J}$ be a nonzero minor of order p. If all the minors of order $p + 1$ bordering M vanish, then $\operatorname{rank} A = p$, and the columns of A with indices in J form a basis of its column space (and the rows with indices in I a basis of its row space).*

Proof. As in the proof of Proposition 11.6.9, the columns a_l, $l \in J$, are independent. We show that every other column a_j, $j \notin J$, is a combination of them; then they form a basis of the column space, and $\operatorname{rank} A = p$. Fix $j \notin J$, and for each row index i consider the $(p+1)\times(p+1)$ matrix

$$N_i = \begin{pmatrix} A_{I,J} & (a_{i'j})_{i'\in I} \\ (a_{il})_{l\in J} & a_{ij} \end{pmatrix},$$

formed by the rows I followed by row i, and the columns J followed by column j; this ordering changes $\det N_i$ at most by a sign compared with the minor $\det A_{I\cup\{i\},J\cup\{j\}}$. We claim $\det N_i = 0$ for every i. If $i \notin I$, it is a bordering minor up to sign, and vanishes by hypothesis. If $i \in I$, the last row of N_i repeats one of the first p rows, and the determinant of a matrix with two equal rows is 0 (Proposition 11.5.3(2)).

Expand $\det N_i$ along its last row (the Laplace expansion along a row, which follows from Proposition 11.5.3(2) and (3)):

$$0 = \det N_i = \sum_{l\in J} c_l a_{il} + M a_{ij},$$

where $M = \det A_{I,J}$ is the cofactor of the corner entry a_{ij} and c_l is, up to sign, the determinant of the $p \times p$ matrix obtained by deleting the last row and the column of l. These cofactors only involve the rows I of A, so they *do not depend on* i. Since $M \neq 0$, $a_{ij} = -\sum_{l\in J}(c_l/M)a_{il}$ for every i, that is,

$$a_j = -\sum_{l\in J} \frac{c_l}{M}\, a_l.$$

The statement about rows follows by applying this to the transpose, whose minors are those of A (Proposition 11.5.3(2)): the transposes of the bordering minors are the bordering minors of M in A^T. □

This gives a procedure for computing the rank: find a nonzero entry (a nonzero minor of order 1); compute the minors bordering it; if all vanish the rank is 1, otherwise a nonzero one is a minor of order 2, whose bordering minors are computed next, and so on. The procedure stops at the rank, and at each step only the bordering minors of the current minor are needed.

Example 11.6.11. 1. The matrix of Example 11.6.6,

$$A = \begin{pmatrix} 1 & 2 & 1 & 0 \\ 2 & 4 & 0 & 2 \\ 3 & 6 & 1 & 2 \end{pmatrix},$$

has the nonzero minor $M = \det\left(\begin{smallmatrix} 1 & 1 \\ 2 & 0 \end{smallmatrix}\right) = -2$ in rows 1, 2 and columns 1, 3. The bordering minors use row 3 and column 2 or 4:

$$\det\begin{pmatrix} 1 & 2 & 1 \\ 2 & 4 & 0 \\ 3 & 6 & 1 \end{pmatrix} = 0, \qquad \det\begin{pmatrix} 1 & 1 & 0 \\ 2 & 0 & 2 \\ 3 & 1 & 2 \end{pmatrix} = 1\cdot(0-2) - 1\cdot(4-6) + 0 = 0,$$

the first because its second column is twice the first. So $\operatorname{rank} A = 2$ after computing two determinants of order 3, instead of all four.

2. *A rank depending on a parameter.* Let $t \in \mathbb{R}$ and

$$A_t = \begin{pmatrix} 1 & t & 1 \\ t & 1 & 1 \\ 1 & 1 & t \end{pmatrix}.$$

Expanding along the first row, $\det A_t = (t-1) - t(t^2-1) + (t-1) = (t-1)(2-t-t^2) = -(t-1)^2(t+2)$. So $\operatorname{rank} A_t = 3$ for $t \neq 1, -2$. For $t = 1$ all entries equal 1, all minors of order 2 vanish, and the rank is 1. For $t = -2$ the minor $\det\left(\begin{smallmatrix} 1 & -2 \\ -2 & 1 \end{smallmatrix}\right) = -3$ is nonzero and the only bordering minor is $\det A_{-2} = 0$, so the rank is 2. Gaussian elimination would require dividing by expressions in t and keeping track of when they vanish; the minors give the answer directly.

Remark 11.6.12. Proposition 11.6.9 has consequences that are not obvious from the definition of the rank.

1. *The rank does not depend on the field.* If $k \subseteq L$ is a field extension and A has entries in k, its minors are the same whether computed in k or in L; so the rank of A over L equals its rank over k. For instance a real matrix has the same rank over $\mathbb{C}$, and a system with rational coefficients that has a real solution has a rational one (Theorem 11.6.5).

2. *The rank is lower semicontinuous.* For $k = \mathbb{R}$ or $\mathbb{C}$ the minors are polynomial, hence continuous, functions of the entries. So the set of matrices of rank at least r, where some minor of order r is nonzero, is open in $M_{m\times n}(k)$, and a small perturbation can only increase the rank; the set of matrices of rank at most r is closed, the common zero set of the minors of order $r+1$. These zero sets are the *determinantal varieties*, a basic family of examples in algebraic geometry.

11.7 Eigenvalues

In this section V is a vector space of finite dimension n and $f : V \to V$ is linear.

Definition 11.7.1. A scalar $\lambda \in k$ is an *eigenvalue* of f if $\ker(f - \lambda) \neq 0$; the nonzero elements of the *eigenspace* $V_\lambda = \ker(f - \lambda)$ are *eigenvectors*. The *characteristic polynomial* is $\chi_f(x) = \det(xI - A) \in k[x]$ for the matrix A of f in any basis; it is monic of degree n and independent of the basis. The *trace* of f is $\operatorname{tr} f = \sum_i a_{ii}$. The map f is *diagonalisable* if V has a basis of eigenvectors.

Proposition 11.7.2. 1. *The eigenvalues of f are the roots of χ_f in k.*

2. *$\chi_f(x) = x^n - (\operatorname{tr} f)x^{n-1} + \cdots + (-1)^n \det f$; in particular the trace is independent of the basis.*

3. *Eigenvectors with pairwise distinct eigenvalues are linearly independent.*

Proof. (1) λ is an eigenvalue iff $\lambda - f$ is not injective iff $\det(\lambda I - A) = 0$, by Theorem 11.2.6 and Proposition 11.5.3(5). (2) In the Leibniz expansion of $\det(xI - A)$ only $\sigma = \mathrm{id}$ contributes to the coefficients of x^n and x^{n-1}, since any other permutation moves at least two indices; evaluate at $x = 0$ for the constant term. (3) Suppose $\sum_{i=1}^m c_i v_i = 0$ with m minimal and all $c_i \neq 0$. Applying $f - \lambda_m$ gives $\sum_{i<m} c_i(\lambda_i - \lambda_m)v_i = 0$, a shorter relation with nonzero coefficients. □

Theorem 11.7.3 (Cayley–Hamilton)**.** $\chi_f(f) = 0$.

Proof. Let A be the matrix of f. By Proposition 11.5.3(4) over $R = k[x]$, $(xI - A)\operatorname{adj}(xI - A) = \chi_f(x)I$. The entries of $\operatorname{adj}(xI - A)$ have degree $< n$, so we can write $\operatorname{adj}(xI - A) = \sum_{i=0}^{n-1} B_i x^i$ with $B_i \in M_n(k)$; write $\chi_f = \sum_{i=0}^n c_i x^i$. Comparing coefficients of x^i: $B_{i-1} - AB_i = c_i I$ for $0 \le i \le n$, with $B_{-1} = B_n = 0$. Multiplying the i-th equation by A^i on the left and summing, the left sides telescope to 0, so $\sum_i c_i A^i = 0$. □

Definition 11.7.4. The *minimal polynomial* m_f is the monic generator of the ideal $\{p \in k[x] : p(f) = 0\}$, which is nonzero by Theorem 11.7.3. So $m_f \mid \chi_f$.

Lemma 11.7.5 (Kernel lemma)**.** *If $p, q \in k[x]$ are coprime, then* $\ker(pq)(f) = \ker p(f) \oplus \ker q(f)$.

Proof. Write $1 = ap + bq$. For $v \in \ker(pq)(f)$, $v = a(f)p(f)v + b(f)q(f)v$, where the first term lies in $\ker q(f)$ (since $q(f)a(f)p(f)v = a(f)(pq)(f)v = 0$) and the second in $\ker p(f)$. If $v \in \ker p(f) \cap \ker q(f)$ then $v = a(f)p(f)v + b(f)q(f)v = 0$. □

Theorem 11.7.6. *f is diagonalisable if and only if m_f is a product of distinct monic linear factors. In that case $V = \bigoplus_\lambda V_\lambda$ over the eigenvalues. Commuting diagonalisable endomorphisms are simultaneously diagonalisable.*

Proof. If V has a basis of eigenvectors with distinct eigenvalues $\lambda_1, \dots, \lambda_r$, then $\prod_i (f - \lambda_i) = 0$, so m_f divides $\prod_i (x - \lambda_i)$. Conversely if $m_f = \prod_i (x - \lambda_i)$ with distinct λ_i, the kernel lemma gives $V = \ker m_f(f) = \bigoplus_i \ker(f - \lambda_i)$. If g commutes with f, it preserves each V_λ, and its restriction to V_λ has minimal polynomial dividing m_g, hence is diagonalisable; choose eigenbases of these restrictions. □

Example 11.7.7. *Diagonalising a matrix, and what it is good for.* Let $A = \left(\begin{smallmatrix} 4 & 1 \\ 2 & 3 \end{smallmatrix}\right)$.

1. The characteristic polynomial is $\det(xI - A) = (x-4)(x-3) - 2 = x^2 - 7x + 10 = (x-2)(x-5)$, so the eigenvalues are 2 and 5; note $2 + 5 = 7 = \operatorname{tr} A$ and $2 \cdot 5 = 10 = \det A$, as Proposition 11.7.2(2) predicts.

2. Eigenvectors: $A - 2I = \left(\begin{smallmatrix} 2 & 1 \\ 2 & 1 \end{smallmatrix}\right)$ has kernel spanned by $(1, -2)$, and $A - 5I = \left(\begin{smallmatrix} -1 & 1 \\ 2 & -2 \end{smallmatrix}\right)$ by $(1, 1)$. They are independent (distinct eigenvalues), so with $P = \left(\begin{smallmatrix} 1 & 1 \\ -2 & 1 \end{smallmatrix}\right)$, whose columns are the eigenvectors, $P^{-1}AP = \operatorname{diag}(2, 5)$ by Proposition 11.3.3.

3. Powers become easy: $A^n = P \operatorname{diag}(2^n, 5^n) P^{-1}$, and with $P^{-1} = \frac{1}{3}\left(\begin{smallmatrix} 1 & -1 \\ 2 & 1 \end{smallmatrix}\right)$,

$$A^n = \frac{1}{3} \begin{pmatrix} 2^n + 2 \cdot 5^n & 5^n - 2^n \\ 2 \cdot 5^n - 2^{n+1} & 2^{n+1} + 5^n \end{pmatrix},$$

   which for $n = 1$ gives back A. For large n, $A^n \approx \frac{5^n}{3}\left(\begin{smallmatrix} 2 & 1 \\ 2 & 1 \end{smallmatrix}\right)$: the largest eigenvalue dominates.

4. *Fibonacci numbers.* $F_0 = 0$, $F_1 = 1$, $F_{n+1} = F_n + F_{n-1}$ means $(F_{n+1}, F_n)^T = M(F_n, F_{n-1})^T$ with $M = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. Its characteristic polynomial $x^2 - x - 1$ has the real roots $\varphi = \frac{1+\sqrt{5}}{2}$ and $\psi = \frac{1-\sqrt{5}}{2}$, so M is diagonalisable over $\mathbb{R}$ and $F_n = a\varphi^n + b\psi^n$ for constants determined by F_0 and F_1: $a + b = 0$, $a\varphi + b\psi = 1$, so $a = -b = 1/\sqrt{5}$ and $F_n = (\varphi^n - \psi^n)/\sqrt{5}$ (Binet's formula). As $|\psi| < 1$, F_n is the integer closest to $\varphi^n/\sqrt{5}$.

5. *Cayley–Hamilton for 2×2 matrices* says $A^2 - (\operatorname{tr} A)A + (\det A)I = 0$; here $A^2 = \left(\begin{smallmatrix} 18 & 7 \\ 14 & 11 \end{smallmatrix}\right) = 7A - 10I$. If $\det A \neq 0$ it gives the inverse: $A^{-1} = \frac{1}{\det A}((\operatorname{tr} A)I - A) = \frac{1}{10}\left(\begin{smallmatrix} 3 & -1 \\ -2 & 4 \end{smallmatrix}\right)$, which is the adjugate formula.

Example 11.7.8. A *projection* is an endomorphism with $p^2 = p$. Its minimal polynomial divides $x^2 - x = x(x-1)$, a product of distinct linear factors, so by Theorem 11.7.6 p is diagonalisable with eigenvalues in $\{0, 1\}$, and $V = \ker p \oplus \operatorname{im} p$, with p the identity on $\operatorname{im} p = \ker(p - 1)$. So a projection is the same as a decomposition $V = U \oplus W$, p being the projection onto U along W. Similarly an *involution*, $s^2 = 1$, in characteristic $\neq 2$ is diagonalisable with eigenvalues ± 1, $V = \ker(s - 1) \oplus \ker(s + 1)$: a reflection in the first summand along the second.

Counterexample 11.7.9. The rotation $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ has characteristic polynomial $x^2 + 1$ and no eigenvalue over $\mathbb{R}$, although it is diagonalisable over $\mathbb{C}$. The matrix $N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has $m_N = x^2$ and is not diagonalisable over any field: its only eigenvalue is 0 and $\ker N$ is one-dimensional.

11.8 Canonical forms

Let $f : V \to V$ be as in the previous section. By Example 8.7.2, V is a $k[x]$-module V_f with x acting as f; it is finitely generated and torsion, being annihilated by χ_f.

Definition 11.8.1. The *companion matrix* of a monic $g = x^d + c_{d-1}x^{d-1} + \cdots + c_0$ is the $d \times d$ matrix $C(g)$ with 1's below the diagonal, last column $(-c_0, \ldots, -c_{d-1})^T$ and zeros elsewhere; it is the matrix of multiplication by x on $k[x]/(g)$ in the basis $1, x, \ldots, x^{d-1}$. The *Jordan block* $J_e(\lambda)$ is the $e \times e$ matrix with λ on the diagonal, 1 directly above the diagonal and zeros elsewhere.

Lemma 11.8.2. *The minimal and characteristic polynomials of $C(g)$ both equal g. The minimal and characteristic polynomials of $J_e(\lambda)$ both equal $(x-\lambda)^e$.*

Proof. On $k[x]/(g)$ a polynomial p acts as zero iff $p \cdot 1 = p$ lies in (g), so the minimal polynomial is g. The characteristic polynomial is monic of degree d and divisible by g (Definition 11.7.4), hence equal to g. The matrix $J_e(\lambda)$ is the matrix of x on $k[x]/((x-\lambda)^e)$ in the basis $(x-\lambda)^{e-1}, \ldots, (x-\lambda), 1$, and the same argument applies. □

Theorem 11.8.3 (Rational canonical form)**.** *There are unique monic polynomials $f_1 \mid f_2 \mid \cdots \mid f_s$ of positive degree such that f has, in a suitable basis, the block diagonal matrix $C(f_1) \oplus \cdots \oplus C(f_s)$. Moreover $m_f = f_s$ and $\chi_f = f_1 \cdots f_s$. Two endomorphisms (or matrices) are similar if and only if they have the same f_i, the* invariant factors*.*

Proof. By Theorem 8.11.3, $V_f \cong \bigoplus_i k[x]/(f_i)$ with $f_1 \mid \cdots \mid f_s$ monic of positive degree (there is no free part since V_f is torsion), uniquely determined. Bases of the summands as in Definition 11.8.1 give the block form. An isomorphism $V_f \cong V_g$ of $k[x]$-modules is the same as a linear isomorphism h with $hf = gh$, so similarity corresponds to isomorphism of modules. The polynomial f_s kills every summand and is the minimal polynomial of the last one, so $m_f = f_s$; the characteristic polynomial of a block matrix is the product of those of the blocks, which gives χ_f by Lemma 11.8.2. □

Theorem 11.8.4 (Jordan normal form)**.** *Suppose χ_f splits into linear factors over k (for instance, k algebraically closed). Then f has, in a suitable basis, a block diagonal matrix $J_{e_1}(\lambda_1) \oplus \cdots \oplus J_{e_r}(\lambda_r)$, and the multiset of pairs (λ_i, e_i) is uniquely determined by f.*

Proof. By Corollary 8.11.4, $V_f \cong \bigoplus_i k[x]/(p_i^{e_i})$ with p_i monic irreducible, uniquely. Each p_i divides χ_f, hence is $x - \lambda_i$. Use the bases of Lemma 11.8.2. □

Example 11.8.5. A nilpotent endomorphism ($f^m = 0$ for some m) over any field has $\chi_f = x^n$ (its only possible eigenvalue is 0, and $m_f \mid x^m$), so it is similar to a direct sum of blocks $J_e(0)$; the sizes of the blocks form a partition of n, and they classify nilpotent endomorphisms up to similarity. Such nilpotent operators, and their Jordan decompositions, organise the limiting behaviour of variations of Hodge structure (Chapter 70).

Example 11.8.6. *Computing a Jordan basis.* The proof is not constructive as written, but the form is computed as follows. For each eigenvalue λ, the generalised eigenspace $V^{(\lambda)} = \ker(f-\lambda)^n$ is invariant, and $V = \bigoplus_\lambda V^{(\lambda)}$ (Lemma 11.7.5); on it $N = f - \lambda$ is nilpotent, and the number of Jordan blocks of size at least j is $\dim \ker N^j - \dim \ker N^{j-1}$ (Exercise 11.12.2). A block of size e corresponds to a *chain* $v, Nv, \ldots, N^{e-1}v$ with $N^e v = 0$, where $v \in \ker N^e \setminus \ker N^{e-1}$; in the basis $N^{e-1}v, \ldots, Nv, v$ the matrix of f is $J_e(\lambda)$. For example let

$$A = \begin{pmatrix} 2 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 2 \end{pmatrix}, \qquad N = A - 2I = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \qquad N^2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

and $N^3 = 0$. Here $\dim\ker N = 1$, $\dim\ker N^2 = 2$, $\dim\ker N^3 = 3$, so there is a single block $J_3(2)$. Take $v_3 = e_3 \notin \ker N^2$, $v_2 = Nv_3 = (1,1,0)$, $v_1 = Nv_2 = (1,0,0)$. Then $Av_1 = 2v_1$, $Av_2 = 2v_2 + v_1$, $Av_3 = 2v_3 + v_2$, so with $P = (v_1\ v_2\ v_3)$, $P^{-1}AP = J_3(2)$. By contrast $B = \operatorname{diag}(J_2(2), 2)$ has $\dim\ker(B-2) = 2$, two blocks, and the same characteristic polynomial $(x-2)^3$ as A; the dimensions of the kernels of the powers distinguish them.

Counterexample 11.8.7. The hypothesis that χ_f splits cannot be dropped. Over $\mathbb{R}$, the rotation matrix $A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ is not similar to any block diagonal matrix of Jordan blocks. Such a matrix is upper triangular, and the determinant of an upper triangular matrix is the product of its diagonal entries (in the Leibniz expansion every other permutation meets an entry below the diagonal), so its characteristic polynomial is $\prod_i (x - a_{ii})$, which splits over $\mathbb{R}$. But similar matrices have the same characteristic polynomial, and $\chi_A = x^2 + 1$ has no real root. The rational canonical form (Theorem 11.8.3) of A over $\mathbb{R}$ is the companion matrix $C(x^2+1)$, which is A itself; over $\mathbb{C}$, where $x^2 + 1 = (x-i)(x+i)$, A is similar to $J_1(i) \oplus J_1(-i)$.

Proposition 11.8.8. *An endomorphism f has a block diagonal matrix of Jordan blocks in some basis if and only if χ_f splits into linear factors over k. Every square matrix over k is similar to such a matrix if and only if k is algebraically closed.*

Proof. If χ_f splits, use Theorem 11.8.4. Conversely, a block diagonal matrix of Jordan blocks $J_{e_i}(\lambda_i)$ is upper triangular, so its characteristic polynomial is $\prod_i (x - \lambda_i)^{e_i}$, as in Counterexample 11.8.7; and χ_f is the characteristic polynomial of any matrix of f. For the second statement, if k is algebraically closed every χ_f splits. If k is not, some monic polynomial g of degree $d \geq 1$ does not split, and the companion matrix $C(g)$ has characteristic polynomial g (Lemma 11.8.2), so it is not similar to a matrix of Jordan blocks. □

When χ_f does not split, the primary decomposition still gives a canonical form. By Corollary 8.11.4, $V_f \cong \bigoplus_i k[x]/(p_i^{e_i})$ with p_i monic irreducible, uniquely, so f is similar to the block diagonal matrix $C(p_1^{e_1}) \oplus \cdots \oplus C(p_r^{e_r})$, the *primary rational canonical form*; for $p_i = x - \lambda_i$ one may use $J_{e_i}(\lambda_i)$ instead of $C(p_i^{e_i})$. Over $\mathbb{R}$ there is a convenient replacement for $C(p^e)$ as well.

Proposition 11.8.9 (Real Jordan form)**.** *For $a \in \mathbb{R}$ and $b > 0$ let $R = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ and let the* real Jordan block *$J_e(a,b)$ be the $2e \times 2e$ block matrix with R on the diagonal, the 2×2 identity matrix directly above the diagonal, and zeros elsewhere. Then $J_e(a,b)$ is similar to $C(p^e)$, where $p = (x-a)^2 + b^2$. Consequently every real square matrix is similar to a block diagonal matrix of blocks $J_e(\lambda)$ with $\lambda \in \mathbb{R}$ and $J_e(a,b)$ with $b > 0$, and the multiset of these blocks is uniquely determined.*

Proof. Write $M = J_e(a,b) = D + N$, where D is block diagonal with blocks R and N has the identity blocks above the diagonal. The matrices D and N commute, since both are built from 2×2 blocks that commute with each other; $N^e = 0$ and $N^{e-1} \neq 0$. The characteristic polynomial of R is p, so $p(R) = 0$ by Theorem 11.7.3 and $p(D) = 0$. Hence

$$p(M) = (D - aI + N)^2 + b^2 I = p(D) + 2(D - aI)N + N^2 = N\big(2(D - aI) + N\big).$$

The matrix $D - aI$ is block diagonal with invertible blocks $\left(\begin{smallmatrix} 0 & -b \\ b & 0 \end{smallmatrix}\right)$, and it commutes with the nilpotent matrix N; so $U = 2(D-aI)+N$ is invertible, with inverse $\sum_{j\geq 0}(-1)^j(2(D-aI))^{-j-1}N^j$, a finite sum. As N and U commute, $p(M)^j = N^j U^j$, which vanishes if and only if $j \geq e$. The minimal polynomial of M divides a power of the irreducible p, so it is p^e; the characteristic polynomial is $\chi_R^e = p^e$, since M is block upper triangular. By Theorem 11.8.3, the invariant factors of M have product p^e and the last one equals p^e, so there is only one, and M is similar

to $C(p^e)$. The monic irreducible real polynomials are the $x-\lambda$ and the $(x-a)^2+b^2$ with $b>0$ (Theorem 9.7.3: a nonreal root $a+ib$ comes with its conjugate), so the last statement follows from the primary rational canonical form. □

For example, the rotation of Counterexample 11.8.7 is the real Jordan block $J_1(0,1)$.

We turn to a decomposition that makes sense without any splitting. An endomorphism s is called *semisimple* if its minimal polynomial is separable (Definition 9.4.1), that is, has no repeated roots in a splitting field. We need that the minimal polynomial does not change under extension of the field.

Lemma 11.8.10. *Let L/k be a field extension and $A \in M_n(k)$. The minimal polynomial of A over L equals its minimal polynomial over k. In particular A is semisimple over k if and only if it is semisimple over L, and A is semisimple if and only if it is diagonalisable over a splitting field of m_A.*

Proof. Let d be the least integer such that $I, A, \dots, A^d$ are linearly dependent over k. Linear dependence of finitely many vectors of k^{n^2} over k or over L means that the matrix having them as columns has rank less than the number of vectors, that is, that all its maximal minors vanish; this does not depend on the field. So d is the same over k and over L, and the relation $A^d = -\sum_{j<d} c_j A^j$ is unique over L, because $I, \dots, A^{d-1}$ are independent over L; as it exists with $c_j \in k$, the minimal polynomials agree. The last statement follows from Theorem 11.7.6, applied over the splitting field. □

Theorem 11.8.11 (Jordan–Chevalley decomposition)**.** *Let k be a perfect field (Definition 9.4.3) and f an endomorphism of V. There are unique endomorphisms s and n of V with $f = s+n$, s semisimple, n nilpotent, and $sn = ns$. Moreover s and n are polynomials in f with coefficients in k.*

Proof. Step 1: existence when χ_f splits, over any field. Let $\chi_f = \prod_i (x-\lambda_i)^{e_i}$ with distinct λ_i. By the kernel lemma (Lemma 11.7.5), $V = \bigoplus_i V_i$ with $V_i = \ker(f-\lambda_i)^{e_i}$, since $\chi_f(f) = 0$. The ideals $((x-\lambda_i)^{e_i})$ are pairwise coprime, so by the Chinese remainder theorem (Theorem 8.3.3) there is $q \in k[x]$ with $q \equiv \lambda_i \bmod (x-\lambda_i)^{e_i}$ for all i. Then $s = q(f)$ acts on V_i as λ_i, so it is diagonalisable, hence semisimple, and $n = f - s$ acts on V_i as $f-\lambda_i$, which is nilpotent there; so n is nilpotent. Both are polynomials in f, so they commute.

Step 2: uniqueness, over any field, for decompositions as in Step 1. Let $f = s'+n'$ be another decomposition. Then s' and n' commute with $f = s'+n'$, hence with the polynomials s and n in f. Now $s - s' = n' - n$. The right side is nilpotent: n and n' commute, so $(n'-n)^{2m}$ is a sum of terms $n'^j n^{2m-j}$ which vanish for m large. The left side is semisimple: over a splitting field L of $m_s m_{s'}$, the commuting endomorphisms s and s' are diagonalisable (Lemma 11.8.10), hence simultaneously diagonalisable (Theorem 11.7.6), so $s-s'$ is diagonalisable over L. A diagonalisable nilpotent endomorphism is 0, as its eigenvalues are 0. So $s = s'$ and $n = n'$.

Step 3: k perfect. Let g be the product of the distinct monic irreducible factors of χ_f. Each is separable because k is perfect (Proposition 9.4.4), and distinct monic irreducible polynomials have no common root, so g is separable. Let L be a splitting field of g; then χ_f splits over L, and L/k is Galois with group G and $L^G = k$ (Theorem 9.5.3). Let $A \in M_n(k)$ be the matrix of f in a basis. By Steps 1 and 2 over L, $A = S+N$ uniquely, with $S = q(A)$ for some $q \in L[x]$. For $\sigma \in G$, applying σ to all entries is a ring automorphism of $M_n(L)$ fixing A, so $A = \sigma(S) + \sigma(N)$, with $\sigma(N)$ nilpotent, $\sigma(S)\sigma(N) = \sigma(N)\sigma(S)$, and $\sigma(S)$ semisimple: its minimal polynomial is $\sigma(m_S)$, which is separable since $am_S + bm_S' = 1$ implies $\sigma(a)\sigma(m_S) + \sigma(b)\sigma(m_S)' = 1$ (Proposition 9.4.2). By uniqueness $\sigma(S) = S$, so the entries of S lie in $L^G = k$. Then S and $N = A - S$ have entries in k, and S is semisimple over k by Lemma 11.8.10. Any decomposition over k is one over L, so uniqueness over k follows from Step 2. Finally, with $d = \deg m_A$, the matrices $I, A, \dots, A^{d-1}$ form a basis of $L[A]$ over L (by the lemma, over L too the minimal polynomial has degree d); writing $S = \sum_j c_j A^j$ and applying σ shows $\sigma(c_j) = c_j$, so the c_j lie in k. □

Counterexample 11.8.12. Perfectness cannot be dropped. Let $k = \mathbb{F}_p(t)$ and f the endomorphism of k^p with matrix $C(x^p - t)$, whose minimal polynomial is $x^p - t$ (Lemma 11.8.2), irreducible but inseparable (Counterexample 9.4.5). As a $k[x]$-module, $V_f \cong k[x]/(x^p - t)$ is a field, so f has no invariant subspaces other than 0 and V: it is "irreducible", the opposite of nilpotent. Yet f is not semisimple, and it has no decomposition $f = s + n$ as in Theorem 11.8.11 with s and n defined over k. Indeed, over $L = k(\beta)$ with $\beta^p = t$ we have $x^p - t = (x - \beta)^p$, so χ_f splits and $f - \beta$ is nilpotent. A decomposition over k would be one over L, where by uniqueness (Steps 1 and 2 of the proof) $s = \beta I$; but $\beta \notin k$. So over imperfect fields "irreducible" and "semisimple" diverge, and the semisimple part of f exists only after an inseparable extension.

11.9 Bilinear forms

Definition 11.9.1. A *bilinear form* on V is a bilinear map $B\colon V \times V \to k$. It is *symmetric* if $B(v, w) = B(w, v)$, *alternating* if $B(v, v) = 0$ for all v, and *nondegenerate* if $v \mapsto B(v, -)$ is an isomorphism $V \to V^*$ (for V finite-dimensional: if $B(v, w) = 0$ for all w implies $v = 0$). Its *Gram matrix* in a basis (v_i) is $(B(v_i, v_j))$. For a subspace W, $W^{\perp_B} = \{v : B(v, w) = 0 \text{ for all } w \in W\}$. A *quadratic form* is $q(v) = B(v, v)$ for a symmetric B.

In coordinates every bilinear form is given by a matrix: if $v = \sum_i x_i v_i$ and $w = \sum_j y_j v_j$, then $B(v, w) = \sum_{i,j} x_i y_j B(v_i, v_j) = x^T G y$, with G the Gram matrix. Conversely every $G \in M_n(k)$ defines the bilinear form $(x, y) \mapsto x^T G y$ on k^n; it is symmetric if and only if $G^T = G$, alternating (in characteristic $\neq 2$) if and only if $G^T = -G$, and nondegenerate if and only if $\det G \neq 0$, since $v \mapsto B(v, -)$ has matrix G^T in the basis (v_i) and the dual basis. Under a change of basis with matrix P the Gram matrix becomes $P^T G P$.

Lemma 11.9.2. *Let B be symmetric or alternating on a finite-dimensional V, and $W \subseteq V$ a subspace on which B is nondegenerate. Then $V = W \oplus W^{\perp_B}$. An alternating form B satisfies $B(v, w) = -B(w, v)$.*

Proof. $W \cap W^{\perp_B} = 0$ by nondegeneracy on W. Given $v \in V$, the functional $B(v, -)|_W$ equals $B(w, -)|_W$ for a unique $w \in W$, and then $v - w \in W^{\perp_B}$ (for alternating forms use $B(-, w) = -B(w, -)$). The last statement follows from expanding $B(v + w, v + w) = 0$. □

Theorem 11.9.3. *Let* $\operatorname{char} k \neq 2$ *and B symmetric on a finite-dimensional V. Then V has a basis (v_i) with $B(v_i, v_j) = 0$ for $i \neq j$.*

Proof. By induction on $\dim V$. If $B = 0$ any basis works. Otherwise some $q(v) \neq 0$: if $B(v, w) \neq 0$ then by the polarisation identity $2B(v, w) = q(v + w) - q(v) - q(w)$ one of $q(v + w)$, $q(v)$, $q(w)$ is nonzero. Then B is nondegenerate on kv, so $V = kv \oplus (kv)^{\perp_B}$ by Lemma 11.9.2; apply induction to $(kv)^{\perp_B}$. □

Counterexample 11.9.4. The hypothesis $\operatorname{char} k \neq 2$ is needed. On $\mathbb{F}_2^2$ the form $B((a, b), (c, d)) = ad + bc$ is symmetric and nondegenerate, but alternating ($B(v, v) = 2ab = 0$). A basis with $B(v_i, v_j) = 0$ for $i \neq j$ would make B zero.

Theorem 11.9.5 (Sylvester's law of inertia)**.** *Let B be a symmetric bilinear form on a real vector space V of dimension n. There is a basis in which the Gram matrix is diagonal with p entries* 1, *q entries* -1 *and $n - p - q$ entries* 0, *and the numbers p and q do not depend on the basis. The pair (p, q) is the* signature *of B.*

Proof. Take an orthogonal basis (Theorem 11.9.3) and rescale each v_i with $q(v_i) \neq 0$ by $|q(v_i)|^{-1/2}$ (Proposition 4.7.4). For uniqueness, p is the largest dimension of a subspace on

which q is positive definite: q is positive definite on the span P of the v_i with $q(v_i) = 1$, and if U is a subspace on which q is positive definite, then U meets the span N of the other basis vectors, on which $q \le 0$, only in 0; so $\dim U \le n - \dim N = p$. Similarly for q. □

Theorem 11.9.6. *Let ω be a nondegenerate alternating form on a finite-dimensional V. Then* $\dim V = 2m$ *is even, and V has a* symplectic basis $e_1, \dots, e_m, f_1, \dots, f_m$ *with $\omega(e_i, f_j) = \delta_{ij}$ and $\omega(e_i, e_j) = \omega(f_i, f_j) = 0$.*

Proof. If $V \neq 0$, choose $e_1 \neq 0$, and f_1 with $\omega(e_1, f_1) = 1$ by nondegeneracy. Then e_1, f_1 are independent (as $\omega(e_1, e_1) = 0$), and ω is nondegenerate on their span W, whose Gram matrix is $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. By Lemma 11.9.2, $V = W \oplus W^{\perp_\omega}$, and ω is nondegenerate on $W^{\perp_\omega}$. Apply induction. □

11.10 Inner product spaces and the spectral theorem

Definition 11.10.1. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. An *inner product* on a $\mathbb{K}$-vector space V is a map $\langle -, - \rangle \colon V \times V \to \mathbb{K}$, linear in the first variable, with $\langle w, v \rangle = \overline{\langle v, w \rangle}$ and $\langle v, v \rangle > 0$ for $v \neq 0$. (Over $\mathbb{C}$ it is then conjugate-linear in the second variable; such a form is also called a *Hermitian inner product*.) We write $\|v\| = \sqrt{\langle v, v \rangle}$. A family is *orthonormal* if $\langle v_i, v_j \rangle = \delta_{ij}$.

Proposition 11.10.2. $|\langle v, w \rangle| \le \|v\|\|w\|$, *and* $\|v + w\| \le \|v\| + \|w\|$.

Proof. If $w = 0$ this is clear. Otherwise let $u = v - \frac{\langle v, w \rangle}{\|w\|^2} w$; then $\langle u, w \rangle = 0$ and $0 \le \|u\|^2 = \|v\|^2 - |\langle v, w \rangle|^2 / \|w\|^2$. For the triangle inequality, $\|v+w\|^2 = \|v\|^2 + 2\,\mathrm{Re}\langle v, w \rangle + \|w\|^2 \le (\|v\| + \|w\|)^2$. □

Theorem 11.10.3 (Gram–Schmidt)**.** *If $v_1, v_2, \dots$ is a finite or countable linearly independent family, there is an orthonormal family $u_1, u_2, \dots$ with* $\mathrm{span}(u_1, \dots, u_j) = \mathrm{span}(v_1, \dots, v_j)$ *for all j. Every finite-dimensional inner product space has an orthonormal basis, and for every finite-dimensional subspace W, $V = W \oplus W^\perp$, where $W^\perp = \{v : \langle v, w \rangle = 0$ for all $w \in W\}$.*

Proof. Define recursively $u'_j = v_j - \sum_{i<j} \langle v_j, u_i \rangle u_i$, which is nonzero since $v_j \notin \mathrm{span}(u_1, \dots, u_{j-1})$, and $u_j = u'_j / \|u'_j\|$. For the last claim, with an orthonormal basis (u_i) of W, write $v = \sum_i \langle v, u_i \rangle u_i + (v - \sum_i \langle v, u_i \rangle u_i)$; the second term lies in $W^\perp$, and $W \cap W^\perp = 0$ by positivity. □

Definition 11.10.4. Let V be a finite-dimensional inner product space and $f \colon V \to V$ linear. The *adjoint* $f^\dagger$ is the unique linear map with $\langle f(v), w \rangle = \langle v, f^\dagger(w) \rangle$ for all v, w. The map f is *self-adjoint* if $f^\dagger = f$, *normal* if $f f^\dagger = f^\dagger f$, and *unitary* (or *orthogonal*, if $\mathbb{K} = \mathbb{R}$) if $f^\dagger f = \mathrm{id}$. The unitary operators of $\mathbb{C}^n$ form the *unitary group* $\mathrm{U}(n)$, and the orthogonal operators of $\mathbb{R}^n$ the *orthogonal group* $\mathrm{O}(n)$.

Lemma 11.10.5. *The adjoint exists and is unique. In an orthonormal basis its matrix is the conjugate transpose of the matrix of f. If W is f-invariant then $W^\perp$ is $f^\dagger$-invariant.*

Proof. With an orthonormal basis (u_i), the map $f^\dagger(w) = \sum_i \langle w, f(u_i) \rangle u_i$ works, and a linear map is determined by the values $\langle v, f^\dagger(w) \rangle$. Its matrix entries are $\langle f^\dagger(u_j), u_i \rangle = \overline{\langle f(u_i), u_j \rangle}$. If $f(W) \subseteq W$ and $v \in W^\perp$, then $\langle f^\dagger(v), w \rangle = \langle v, f(w) \rangle = 0$ for $w \in W$. □

Theorem 11.10.6 (Spectral theorem)**.** *Let V be a finite-dimensional inner product space.*

1. *If $\mathbb{K} = \mathbb{C}$ and f is normal, then V has an orthonormal basis of eigenvectors of f.*
2. *If f is self-adjoint (over $\mathbb{R}$ or $\mathbb{C}$), then all its eigenvalues are real and V has an orthonormal basis of eigenvectors of f.*

Proof. For self-adjoint f and an eigenvector v with eigenvalue λ, $\lambda\|v\|^2 = \langle fv, v\rangle = \langle v, fv\rangle = \bar\lambda\|v\|^2$, so $\lambda \in \mathbb{R}$.

(1) By induction on $\dim V$. By Theorem 9.7.3, χ_f has a root, so f has an eigenvector v. Since f and $f^\dagger$ commute, $f^\dagger$ preserves the eigenspace V_λ, and its restriction there has an eigenvector u; then u is an eigenvector of both f and $f^\dagger$. Then $W = \mathbb{C}u$ is invariant under both, so $W^\perp$ is invariant under $f^\dagger$ and $(f^\dagger)^\dagger = f$ (Lemma 11.10.5), and the restriction of f to $W^\perp$ is normal. Apply induction and normalise u.

(2) Over $\mathbb{C}$ this follows from (1). Over $\mathbb{R}$, choose an orthonormal basis and let A be the real symmetric matrix of f. As a complex matrix acting on $\mathbb{C}^n$ with the standard inner product, A is self-adjoint, so it has an eigenvalue, which is real, and hence a real root λ of χ_f; so f has an eigenvector $u \in V$. The line $\mathbb{R}u$ and its orthogonal complement are invariant under $f = f^\dagger$, and we conclude by induction. □

In matrix form: a real symmetric matrix A can be written $A = QDQ^T$ with Q orthogonal ($Q^TQ = I$) and D diagonal, the columns of Q being an orthonormal basis of eigenvectors and the diagonal of D the eigenvalues; so A is diagonalised by an orthonormal change of basis, for which $Q^{-1} = Q^T$ (Remark 11.3.4). Likewise a Hermitian or normal complex matrix is UDU^* with U unitary. For example $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ has $\chi_A = (x-1)(x-3)$, with unit eigenvectors $(1,-1)/\sqrt{2}$ and $(1,1)/\sqrt{2}$, and $A = QDQ^T$ with $Q = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix}\right)$ and $D = \operatorname{diag}(1,3)$. Eigenvectors for distinct eigenvalues of a self-adjoint map are automatically orthogonal: $\lambda\langle v, w\rangle = \langle fv, w\rangle = \langle v, fw\rangle = \mu\langle v, w\rangle$.

Counterexample 11.10.7. Normality is necessary in (1): the matrix N of Counterexample 11.7.9 is not diagonalisable at all. Over $\mathbb{R}$, normal is not enough: the rotation of that counterexample is orthogonal, hence normal, but has no real eigenvector.

Corollary 11.10.8. *A real symmetric (or complex Hermitian) matrix A defines an inner product $\langle v, w\rangle = w^*Av$ if and only if all its eigenvalues are positive. Every inner product on $\mathbb{R}^n$ (or $\mathbb{C}^n$) is of this form.*

Proof. Diagonalise $A = UDU^*$ with U unitary (Theorem 11.10.6); then $w^*Av = (U^*w)^*D(U^*v)$, which is positive definite iff all diagonal entries of D are positive. The matrix of an inner product in the standard basis is Hermitian. □

Proposition 11.10.9 (Singular value decomposition)**.** *Let $f : V \to W$ be a linear map between finite-dimensional inner product spaces over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$, of rank r. There are orthonormal bases $(v_1, \dots, v_n)$ of V and $(w_1, \dots, w_m)$ of W and real numbers $\sigma_1 \geq \cdots \geq \sigma_r > 0$ with $f(v_i) = \sigma_i w_i$ for $i \leq r$ and $f(v_i) = 0$ for $i > r$. The σ_i^2 are the nonzero eigenvalues of $f^\dagger f$, so the* singular values *σ_i are determined by f; the largest one is the operator norm $\|f\| = \sup_{\|v\|=1} \|f(v)\|$.*

Proof. The endomorphism $f^\dagger f$ of V is self-adjoint and $\langle f^\dagger fv, v\rangle = \|f(v)\|^2 \geq 0$, so by Theorem 11.10.6 there is an orthonormal basis (v_i) of V with $f^\dagger f v_i = \lambda_i v_i$ and $\lambda_i \geq 0$; order it so that $\lambda_1 \geq \lambda_2 \geq \cdots$. Then $\langle f(v_i), f(v_j)\rangle = \langle f^\dagger f v_i, v_j\rangle = \lambda_i\delta_{ij}$, so the $f(v_i)$ are pairwise orthogonal, $f(v_i) = 0$ exactly when $\lambda_i = 0$, and the number of i with $\lambda_i > 0$ is the rank r. Put $\sigma_i = \sqrt{\lambda_i}$ and $w_i = f(v_i)/\sigma_i$ for $i \leq r$; these are orthonormal, and we extend them to an orthonormal basis of W (Theorem 11.10.3). For $v = \sum_i c_i v_i$ of norm one, $\|f(v)\|^2 = \sum_{i\leq r} \sigma_i^2 |c_i|^2 \leq \sigma_1^2$, with equality at $v = v_1$. □

Example 11.10.10. For $f(x, y) = (x + y, 0)$ on $\mathbb{R}^2$, $f^\dagger f$ has matrix $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ with eigenvalues 2 and 0 and eigenvectors $(1,1)/\sqrt{2}$ and $(1,-1)/\sqrt{2}$. So $\sigma_1 = \sqrt{2}$, $w_1 = (1, 0)$, and $\|f\| = \sqrt{2}$, although the eigenvalues of f itself are 1 and 0: for non-normal maps the operator norm is not the largest absolute value of an eigenvalue.

11.11 Complex structures

Definition 11.11.1. Let V be a real vector space. Its *complexification* is $V_{\mathbb{C}} = V \otimes_{\mathbb{R}} \mathbb{C}$, a complex vector space with the *complex conjugation* $\overline{v \otimes z} = v \otimes \bar{z}$, which is $\mathbb{R}$-linear and conjugate-linear over $\mathbb{C}$. A *complex structure* on V is an $\mathbb{R}$-linear map $J\colon V \to V$ with $J^2 = -\mathrm{id}$.

Proposition 11.11.2. *Let J be a complex structure on a finite-dimensional real vector space V.*

1. *V becomes a complex vector space with $(a+bi)v = av + bJv$; hence $\dim_{\mathbb{R}} V = 2\dim_{\mathbb{C}} V$ is even.*
2. *Extend J $\mathbb{C}$-linearly to $V_{\mathbb{C}}$. Then $V_{\mathbb{C}} = V^{1,0} \oplus V^{0,1}$, where $V^{1,0} = \ker(J - i)$ and $V^{0,1} = \ker(J + i)$, and $\overline{V^{1,0}} = V^{0,1}$.*
3. *The map $V \to V^{1,0}$, $v \mapsto \frac{1}{2}(v - iJv)$, is an isomorphism of complex vector spaces from (V, J) to $V^{1,0}$, and $v \mapsto \frac{1}{2}(v + iJv)$ is a conjugate-linear isomorphism $V \to V^{0,1}$.*

Proof. (1) The axioms of a module over $\mathbb{C} = \mathbb{R}[x]/(x^2+1)$ follow from $J^2 = -1$ (Example 8.7.2 and Exercise 8.12.2); a complex basis (v_j) gives the real basis (v_j, Jv_j). (2) The polynomial $x^2 + 1 = (x - i)(x + i)$ kills J on $V_{\mathbb{C}}$, and the kernel lemma (Lemma 11.7.5) gives the decomposition. Conjugation commutes with J (which is real), so it exchanges the $\pm i$-eigenspaces. (3) $J(v - iJv) = Jv + iv = i(v - iJv)$, so the image lies in $V^{1,0}$, and J on V corresponds to multiplication by i. The map is injective because v is recovered as twice the real part, and both sides have complex dimension $\frac{1}{2}\dim_{\mathbb{R}} V$. The second map is the conjugate of the first. □

Proposition 11.11.3. *Let J be a complex structure on a real inner product space (V, g) with $g(Jv, Jw) = g(v, w)$. Put $\omega(v, w) = g(Jv, w)$ and $h = g - i\omega$. Then ω is a nondegenerate alternating form with $\omega(Jv, Jw) = \omega(v, w)$, and h is a Hermitian inner product on the complex vector space (V, J), whose real part is g. Conversely, g and J determine ω, and ω and J determine $g(v, w) = \omega(v, Jw)$.*

Proof. From J-invariance, $g(Jv, w) = g(J^2 v, Jw) = -g(v, Jw)$. Hence $\omega(w, v) = g(Jw, v) = -g(w, Jv) = -\omega(v, w)$, so ω is alternating; $\omega(Jv, Jw) = g(J(Jv), Jw) = g(Jv, w) = \omega(v, w)$ by J-invariance of g; and ω is nondegenerate because $\omega(v, Jv) = g(Jv, Jv) > 0$ for $v \neq 0$. For h: $h(v, w) = g(v, w) + ig(v, Jw)$. Then $h(Jv, w) = g(Jv, w) + ig(Jv, Jw) = -g(v, Jw) + ig(v, w) = ih(v, w)$, so h is complex linear in the first variable; $h(w, v) = g(v, w) - ig(v, Jw) = \overline{h(v, w)}$; and $h(v, v) = g(v, v) > 0$ for $v \neq 0$ since $g(v, Jv) = -g(Jv, v) = -g(v, Jv)$ vanishes. Finally $\omega(v, Jw) = g(Jv, Jw) = g(v, w)$. □

Example 11.11.4. On $\mathbb{R}^{2n}$ with coordinates $(x_1, y_1, \ldots, x_n, y_n)$, the standard complex structure is $J(\partial_{x_j}) = \partial_{y_j}$, $J(\partial_{y_j}) = -\partial_{x_j}$ (writing ∂_{x_j}, ∂_{y_j} for the standard basis vectors), which identifies $(\mathbb{R}^{2n}, J)$ with $\mathbb{C}^n$ via $x + iy$. The standard inner product is J-invariant, the associated form satisfies $\omega(\partial_{x_j}, \partial_{y_j}) = g(\partial_{y_j}, \partial_{y_j}) = 1$, so the ∂_{x_j}, ∂_{y_j} form a symplectic basis, and h is the standard Hermitian inner product of $\mathbb{C}^n$. The vectors $\partial_{z_j} = \frac{1}{2}(\partial_{x_j} - i\partial_{y_j})$ span $V^{1,0}$. These formulas reappear as the local model of Kähler manifolds (Chapter 47).

Proposition 11.11.3 relates three structures on V: an inner product g, a nondegenerate alternating form ω and a complex structure J. We call a triple (g, ω, J) of such structures *compatible* if $g(Jv, Jw) = g(v, w)$ and $\omega(v, w) = g(Jv, w)$ for all v, w. The next proposition says that any two members of a compatible triple determine the third, and says exactly which pairs occur. This "two out of three" property is the linear algebra behind Hermitian and Kähler manifolds (Chapter 47) and behind the compatible complex structures of symplectic geometry (Chapter 41).

Proposition 11.11.5 (Two out of three)**.** *Let V be a finite-dimensional real vector space.*

1. *In a compatible triple (g, ω, J) each member is determined by the other two:*

$$\omega(v,w) = g(Jv,w), \qquad g(v,w) = \omega(v,Jw), \qquad J \text{ is the unique endomorphism with } \omega(v,w) = g(Jv,w).$$

2. *A pair extends to a compatible triple exactly in the following cases.*
   (a) *An inner product g and a complex structure J: if and only if $g(Jv,Jw) = g(v,w)$.*
   (b) *A nondegenerate alternating form ω and a complex structure J: if and only if $\omega(Jv,Jw) = \omega(v,w)$ and $\omega(v,Jv) > 0$ for all $v \neq 0$.*
   (c) *An inner product g and a nondegenerate alternating form ω: let A be the endomorphism with $\omega(v,w) = g(Av,w)$; the pair extends if and only if $A^2 = -1$, equivalently, if and only if A is orthogonal for g; and then $J = A$.*

3. *Let (g, ω, J) be compatible, and $h = g - i\omega$ the Hermitian inner product of Proposition 11.11.3. An automorphism of V preserving two of g, ω, J (preserving J meaning $TJ = JT$) preserves the third. So the three groups $\mathrm{O}(V,g)$, $\mathrm{Sp}(V,\omega)$ and $\mathrm{GL}(V,J)$ of automorphisms preserving g, ω and J satisfy*

$$\mathrm{O}(V,g) \cap \mathrm{Sp}(V,\omega) = \mathrm{O}(V,g) \cap \mathrm{GL}(V,J) = \mathrm{Sp}(V,\omega) \cap \mathrm{GL}(V,J) = \mathrm{U}(V,h),$$

the unitary group of h on the complex vector space (V,J). For $\mathbb{R}^{2n} = \mathbb{C}^n$ with its standard structures this reads $\mathrm{O}(2n) \cap \mathrm{Sp}_{2n}(\mathbb{R}) = \mathrm{O}(2n) \cap \mathrm{GL}_n(\mathbb{C}) = \mathrm{Sp}_{2n}(\mathbb{R}) \cap \mathrm{GL}_n(\mathbb{C}) = \mathrm{U}(n)$.

Proof. (1) The first two formulas are in Proposition 11.11.3. If $g(Jv,w) = g(J'v,w)$ for all w, then $Jv = J'v$, as g is nondegenerate.

(2)(a) is Proposition 11.11.3. For (b), if the triple is compatible, ω is J-invariant by that proposition and $\omega(v,Jv) = g(Jv,Jv) > 0$ for $v \neq 0$. Conversely, define $g(v,w) = \omega(v,Jw)$. Using J-invariance of ω and $J^2 = -1$,

$$g(w,v) = \omega(w,Jv) = \omega(Jw,J^2v) = -\omega(Jw,v) = \omega(v,Jw) = g(v,w),$$

so g is symmetric; it is positive definite by hypothesis; $g(Jv,Jw) = \omega(Jv,J^2w) = -\omega(Jv,w) = \omega(w,Jv) = g(w,v) = g(v,w)$; and $g(Jv,w) = \omega(Jv,Jw) = \omega(v,w)$. So (g,ω,J) is compatible. For (c), $v \mapsto \omega(v,\cdot)$ is a linear form, represented through g by a unique vector Av (Proposition 11.4.2(1) and nondegeneracy of g), and A is linear. It is skew-adjoint: $g(Av,w) = \omega(v,w) = -\omega(w,v) = -g(Aw,v) = -g(v,Aw)$. If the pair extends, $J = A$ by (1), so $A^2 = -1$. Conversely, if $A^2 = -1$, then $J = A$ is a complex structure, $g(Jv,Jw) = -g(v,J^2w) = g(v,w)$ by skew-adjointness, and $\omega(v,w) = g(Jv,w)$ by definition. Finally, the adjoint of A is $-A$, so A is orthogonal, $A^*A = 1$, if and only if $-A^2 = 1$.

(3) Let T be an automorphism. If T preserves g and commutes with J, then $\omega(Tv,Tw) = g(JTv,Tw) = g(TJv,Tw) = g(Jv,w) = \omega(v,w)$. If T preserves ω and commutes with J, then $g(Tv,Tw) = \omega(Tv,JTw) = \omega(Tv,TJw) = \omega(v,Jw) = g(v,w)$. If T preserves g and ω, then for all v, w

$$g(JTv,Tw) = \omega(Tv,Tw) = \omega(v,w) = g(Jv,w) = g(TJv,Tw),$$

and since Tw runs through all of V, $JTv = TJv$. This proves the equality of the three intersections. An element of $\mathrm{GL}(V,J)$ is a complex linear automorphism of (V,J); it preserves g and ω if and only if it preserves $h = g - i\omega$, that is, if and only if it is unitary. For the standard structures on $\mathbb{R}^{2n}$, $\mathrm{GL}(V,J) = \mathrm{GL}_n(\mathbb{C})$ and $\mathrm{U}(V,h) = \mathrm{U}(n)$ (Example 11.11.4). □

Example 11.11.6. 1. On $\mathbb{R}^2$ with the standard inner product g and $\omega = c\,dx \wedge dy$, $c > 0$, the endomorphism A of (2)(c) is c times the rotation by $\pi/2$: $\omega(e_1, e_2) = c = g(Ae_1, e_2)$. So $A^2 = -c^2$, and the pair (g, ω) is compatible only for $c = 1$. For $c \neq 1$, rescaling g by c makes it compatible with ω and $J = A/c$. Similarly (ω, J) with $\omega = dx \wedge dy$ and J the rotation by $-\pi/2$ satisfies $\omega(Jv, Jw) = \omega(v, w)$ but $\omega(v, Jv) < 0$: the condition of positivity in (2)(b) singles out one of the two orientations.

2. *A pair that is not compatible.* On $\mathbb{R}^4$ with the standard inner product, let $\omega = dx^1 \wedge dy^1 + 2\,dx^2 \wedge dy^2$. Then A is the rotation by $\pi/2$ in the first plane and twice the rotation by $\pi/2$ in the second, $A^2 = \operatorname{diag}(-1, -1, -4, -4)$, and no complex structure is compatible with both g and ω.

Remark 11.11.7. An incompatible pair (g, ω) can be repaired canonically. With A as in (2)(c), $-A^2 = A^*A$ is self-adjoint and positive definite, so by the spectral theorem (Theorem 11.10.6) it has a unique positive definite square root P, which acts on each eigenspace of $-A^2$ as the positive square root of the eigenvalue; being a polynomial in A^2, P commutes with A. Put $J = AP^{-1}$ (the polar decomposition of A). Then $J^2 = A^2P^{-2} = -1$; using that P is self-adjoint, that A is skew-adjoint and that $AP = PA$,

$$\omega(Jv, Jw) = g(A^2P^{-1}v, AP^{-1}w) = -g(Pv, AP^{-1}w) = -g(v, Aw) = \omega(v, w), \qquad \omega(v, Jv) = g(Av, AP^{-1}v) = g($$

So J is compatible with ω in the sense of (2)(b), with the new inner product $\omega(v, Jw) = g(Pv, w)$, and $J = A$ when (g, ω) was already compatible. Since J depends only on g and ω, and continuously so, this produces compatible complex structures on every symplectic vector space, and indeed compatible almost complex structures on every symplectic manifold, from any Riemannian metric [MS17]. In Example 11.11.6(2), $P = \operatorname{diag}(1, 1, 2, 2)$ and J is the standard complex structure.

11.12 Exercises

Exercise 11.12.1. Show that $\operatorname{tr}(AB) = \operatorname{tr}(BA)$ for $A \in M_{m\times n}(k)$, $B \in M_{n\times m}(k)$, and deduce that similar matrices have the same trace. Show that if $\chi_f = \prod_i (x - \lambda_i)$ then $\operatorname{tr} f = \sum \lambda_i$ and $\det f = \prod \lambda_i$.

Exercise 11.12.2. Suppose χ_f splits. Show that the number of Jordan blocks $J_e(\lambda)$ with $e \geq j$ in the Jordan form of f is $\dim \ker(f - \lambda)^j - \dim \ker(f - \lambda)^{j-1}$.

Exercise 11.12.3. Let V be a finite-dimensional complex vector space and $\mathcal{F}$ a set of pairwise commuting endomorphisms. Show that there is a basis in which all elements of $\mathcal{F}$ are upper triangular.

Exercise 11.12.4. Show that every invertible complex matrix is uniquely $A = UP$ with U unitary and P Hermitian with positive eigenvalues.

Exercise 11.12.5. Let ω be a nondegenerate alternating form on V of dimension $2m$ and $\operatorname{Sp}(V, \omega)$ the group of $f \in \operatorname{GL}(V)$ with $\omega(fv, fw) = \omega(v, w)$. Show that $\det f = \pm 1$ for $f \in \operatorname{Sp}(V, \omega)$. (It is in fact always 1; this can be shown using the Pfaffian, Chapter 12.)

Exercise 11.12.6. Show that the set of complex structures J on $\mathbb{R}^2$ compatible with the standard inner product and with $\omega(e_1, e_2) > 0$ has exactly one element.

Exercise 11.12.7. Let $q(x_1, x_2) = x_1^2 + 4x_1x_2 + x_2^2$ on $\mathbb{R}^2$, with Gram matrix $G = \left(\begin{smallmatrix} 1 & 2 \\ 2 & 1 \end{smallmatrix}\right)$.

1. Complete the square to find a change of variables $x = Py$ with $q = y_1^2 - 3y_2^2$, and check that $P^TGP = \operatorname{diag}(1,-3)$ but that $P^{-1}GP$ is not diagonal.

2. Find an orthogonal Q with $Q^TGQ = Q^{-1}GQ$ diagonal.

3. Compare the two diagonal forms with Sylvester's law of inertia, and explain why they are congruent but not similar.

Solution. (1) $q = (x_1 + 2x_2)^2 - 3x_2^2$, so $y_1 = x_1 + 2x_2$, $y_2 = x_2$, that is, $x = Py$ with $P = \left(\begin{smallmatrix} 1 & -2 \\ 0 & 1 \end{smallmatrix}\right)$. Then $GP = \left(\begin{smallmatrix} 1 & 0 \\ 2 & -3 \end{smallmatrix}\right)$, $P^TGP = \operatorname{diag}(1,-3)$, while $P^{-1} = \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right)$ gives $P^{-1}GP = \left(\begin{smallmatrix} 5 & -6 \\ 2 & -3 \end{smallmatrix}\right)$. (2) The eigenvalues of G are 3 and -1, with unit eigenvectors $(1,1)/\sqrt{2}$ and $(1,-1)/\sqrt{2}$; with these as columns, Q is orthogonal and $Q^TGQ = Q^{-1}GQ = \operatorname{diag}(3,-1)$. (3) Both diagonal matrices have one positive and one negative entry, signature $(1,1)$, so they are congruent, as Sylvester's law requires; they are not similar, since their eigenvalues $\{1,-3\}$ and $\{3,-1\}$ differ. The matrix $P^{-1}GP$ of (1), similar to G, has eigenvalues 3 and -1, as it must. □

Exercise 11.12.8. Show that the reduced row echelon form R of a matrix A in Theorem 11.6.4 is unique: it depends only on A, not on the row operations used.

Solution. By Lemma 11.6.2 the columns of R satisfy the same linear relations as the columns of A. Column j of R is a pivot column exactly when it is not a combination of the columns before it (a pivot column e_s is not a combination of earlier columns, which vanish in row s; a non-pivot column has zeros below the row of the last pivot to its left, so it is a combination of the earlier pivot columns $e_1, \dots, e_s$). So the pivot positions are determined by A. A non-pivot column j of R equals $\sum_s c_s e_s$, the sum over the pivot columns e_s before it, and the coefficients c_s are the unique coefficients expressing column j of A as a combination of the pivot columns of A before it. So every column of R is determined by A. □

Exercise 11.12.9. For which $a \in \mathbb{R}$ does the system $x + y + z = 1$, $x + ay + z = 1$, $x + y + az = 2$ have solutions? Find them.

Solution. The matrix of the system has determinant $(a-1)^2$: subtracting the first row from the others gives rows $(0, a-1, 0)$ and $(0, 0, a-1)$. For $a \neq 1$ the solution is unique: the differences of the equations give $(a-1)y = 0$ and $(a-1)z = 1$, so $y = 0$, $z = 1/(a-1)$ and $x = 1 - 1/(a-1) = (a-2)/(a-1)$, as Cramer's rule also gives. For $a = 1$ the matrix has rank 1 and the augmented matrix has rank 2 (the minor $\det\left(\begin{smallmatrix} 1 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ from the first and third rows, first and last columns, is 1), so by Theorem 11.6.5 there is no solution: the equations $x + y + z = 1$ and $x + y + z = 2$ contradict each other. □

Exercise 11.12.10. Compute the rank of

$$A = \begin{pmatrix} 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & -1 & 0 \\ 2 & 1 & 1 & 2 \end{pmatrix}$$

with the bordered minors theorem, and find a basis of its column space.

Solution. The minor $M = \det\left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right) = -1$ in rows 1, 2 and columns 1, 2 is nonzero. Its four bordering minors use row 3 or 4 and column 3 or 4; they all vanish, because row 3 is row 1 minus row 2 and row 4 is row 1 plus row 2, so each bordering 3×3 matrix has dependent rows. So $\operatorname{rank} A = 2$, and the first two columns form a basis of the column space (indeed column 3 is column 1 minus column 2, and column 4 equals column 1). □

Exercise 11.12.11. Show that $\operatorname{rank}(AB) \le \min(\operatorname{rank} A, \operatorname{rank} B)$ and $\operatorname{rank}(A+B) \le \operatorname{rank} A + \operatorname{rank} B$ for matrices of compatible sizes, and that $\operatorname{rank}(PAQ) = \operatorname{rank} A$ for invertible P and Q. Deduce that every matrix of rank r can be written as $P\left(\begin{smallmatrix} I_r & 0 \\ 0 & 0 \end{smallmatrix}\right)Q$ with P, Q invertible.

Solution. The image of AB is contained in the image of A, and it is the image under A of the image of B, whose dimension is at most $\operatorname{rank} B$. The image of $A+B$ is contained in $\operatorname{im} A + \operatorname{im} B$. If P and Q are invertible, $\operatorname{rank}(PAQ) \le \operatorname{rank} A = \operatorname{rank}(P^{-1}(PAQ)Q^{-1}) \le \operatorname{rank}(PAQ)$. For the normal form, bring A to reduced row echelon form by row operations, then use column operations (multiplication on the right) to move the pivot columns to the front and to clear the remaining entries of the first r rows, which are multiples of the pivot columns $e_1, \dots, e_r$. □

Exercise 11.12.12. Find the polynomial $p \in \mathbb{Q}[x]$ of degree at most 3 with $p(-1) = 2$, $p(0) = 1$, $p(1) = 2$ and $p(2) = 11$, first with the Lagrange polynomials of Example 11.2.2(2), then by solving the linear system for the coefficients. Why is there exactly one?

Solution. With $a_0, a_1, a_2, a_3 = -1, 0, 1, 2$:

$$L_0 = -\tfrac{1}{6}x(x-1)(x-2), \quad L_1 = \tfrac{1}{2}(x+1)(x-1)(x-2), \quad L_2 = -\tfrac{1}{2}(x+1)x(x-2), \quad L_3 = \tfrac{1}{6}(x+1)x(x-1),$$

and $p = 2L_0 + L_1 + 2L_2 + 11L_3$. Expanding, the coefficients of x^3 are $-\frac{1}{3} + \frac{1}{2} - 1 + \frac{11}{6} = 1$, of x^2 are $1 - 1 + 1 + 0 = 1$, of x are $-\frac{2}{3} - \frac{1}{2} + 2 - \frac{11}{6} = -1$, and the constant term is $L_1(0) = 1$; so $p = x^3 + x^2 - x + 1$. Directly, $p = c_0 + c_1x + c_2x^2 + c_3x^3$ must satisfy $c_0 = 1$, $c_0 + c_1 + c_2 + c_3 = 2$, $c_0 - c_1 + c_2 - c_3 = 2$ and $c_0 + 2c_1 + 4c_2 + 8c_3 = 11$; the second and third equations give $c_2 = 1$ and $c_1 + c_3 = 0$, and the last then gives $2c_1 + 8c_3 = 6$, so $c_3 = 1$ and $c_1 = -1$. There is exactly one solution because the Lagrange polynomials form a basis of $\mathbb{Q}[x]_{\le 3}$, in which the coordinates of p are its four prescribed values. □

Exercise 11.12.13. Let $a_0, \dots, a_d \in k$ be distinct and $\operatorname{ev}\colon k[x]_{\le d} \to k^{d+1}, p \mapsto (p(a_0), \dots, p(a_d))$.

1. Show that ev is linear and that its matrix with respect to the bases $1, x, \dots, x^d$ and $e_0, \dots, e_d$ is the Vandermonde matrix $V = (a_i^j)_{0 \le i,j \le d}$.
2. Deduce from the Vandermonde determinant (Example 11.5.4) that ev is an isomorphism, which gives a second proof that interpolation is always possible and unique.
3. Show that $\operatorname{ev}^{-1}(e_i) = L_i$, so that the columns of V^{-1} are the coefficient vectors of the Lagrange polynomials.
4. What happens if two of the a_i coincide?

Solution. (1) $(p+q)(a) = p(a) + q(a)$ and $(cp)(a) = cp(a)$. The j-th basis vector x^j is sent to $(a_0^j, \dots, a_d^j)$, which is the j-th column of V. (2) $\det V = \prod_{i<j}(a_j - a_i) \neq 0$ because the a_i are distinct, so V is invertible, and ev is a linear map between spaces of dimension $d+1$ with invertible matrix. So for each $(b_0, \dots, b_d)$ there is exactly one p of degree at most d with $p(a_i) = b_i$. (3) $L_i(a_l) = 1$ for $l = i$ and 0 otherwise, that is, $\operatorname{ev}(L_i) = e_i$. The i-th column of V^{-1} is the coordinate vector of $\operatorname{ev}^{-1}(e_i) = L_i$ in the basis of monomials. (4) If $a_i = a_l$ with $i \neq l$, two rows of V coincide and $\det V = 0$: the values at a_i and a_l must agree, so ev is not surjective, and since the dimensions agree it is not injective either: the nonzero polynomial $\prod_{j \neq l}(x - a_j)$, of degree d, vanishes at all the given points. □

Exercise 11.12.14. With the notation of Example 11.2.2(2), show that $\sum_{i=0}^{d} L_i = 1$, and more generally $\sum_{i=0}^{d} a_i^m L_i = x^m$ for $0 \le m \le d$. By comparing coefficients of x^d, deduce that

$$\sum_{i=0}^{d} \frac{a_i^m}{\prod_{j \neq i}(a_i - a_j)} = \begin{cases} 0 & 0 \le m < d, \\ 1 & m = d. \end{cases}$$

Check the case $d = 1$ by hand.

Solution. Apply $p = \sum_i p(a_i)L_i$ to $p = x^m$, which has degree $m \le d$: this gives $x^m = \sum_i a_i^m L_i$, and $m = 0$ gives $\sum_i L_i = 1$. The coefficient of x^d in L_i is $1/\prod_{j\neq i}(a_i - a_j)$, since the numerator $\prod_{j\neq i}(x - a_j)$ is monic of degree d. The coefficient of x^d in x^m is 0 for $m < d$ and 1 for $m = d$. For $d = 1$: $\frac{1}{a_0-a_1} + \frac{1}{a_1-a_0} = 0$ and $\frac{a_0}{a_0-a_1} + \frac{a_1}{a_1-a_0} = \frac{a_0-a_1}{a_0-a_1} = 1$. □

Exercise 11.12.15. Let $a_0, \dots, a_d \in k$ be distinct and $f = \prod_i (x - a_i)$. Show that the map $k[x]/(f) \to k^{d+1}$, $p + (f) \mapsto (p(a_0), \dots, p(a_d))$, is a well-defined isomorphism of rings (with the product taken componentwise on k^{d+1}), and that it is the Chinese remainder theorem (Theorem 8.3.3) for the ideals $(x - a_i)$. Show that the classes of the L_i are the idempotents corresponding to the e_i, that is, $L_i^2 \equiv L_i$, $L_i L_l \equiv 0$ for $i \neq l$, and $\sum_i L_i \equiv 1$ modulo f.

Solution. Evaluation at the a_i is a ring homomorphism $k[x] \to k^{d+1}$ that kills f, so it factors through $k[x]/(f)$ (Theorem 8.3.2). The ideals $(x - a_i)$ are pairwise comaximal, since $(x - a_i) - (x - a_l) = a_l - a_i$ is a unit; their product, which equals their intersection, is (f); and $k[x]/(x - a_i) \cong k$ by $p \mapsto p(a_i)$ (Corollary 8.6.7). So the Chinese remainder theorem gives exactly this isomorphism. Alternatively: by division with remainder every class has a unique representative of degree at most d, and on $k[x]_{\le d}$ the map is the linear isomorphism of Exercise 11.12.13. The L_i map to e_i, and $e_i^2 = e_i$, $e_i e_l = 0$ for $i \neq l$, $\sum_i e_i = (1, \dots, 1)$; since the map is injective, the same relations hold for the classes of the L_i. □

Exercise 11.12.16. *(Secret sharing.)* Let p be a prime, $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$, and $1 \le t \le n < p$. To share a secret $s \in \mathbb{F}_p$ among n people so that any t of them together can recover it, choose $c_1, \dots, c_{t-1} \in \mathbb{F}_p$ at random, let $q = s + c_1 x + \cdots + c_{t-1}x^{t-1}$, and give person i the value $q(i)$, for $i = 1, \dots, n$. Show:

1. any t people can compute s, by the formula $s = \sum_i q(a_i)L_i(0)$ over their indices a_i;
2. any $t - 1$ people learn nothing: for every candidate $s' \in \mathbb{F}_p$ there is exactly one polynomial of degree at most $t - 1$ with constant term s' taking the values they hold.

This is Shamir's scheme, [Sha79].

Solution. (1) The indices $1, \dots, n$ are distinct in $\mathbb{F}_p$ because $n < p$. Given t distinct indices $a_1, \dots, a_t$ and the values $q(a_i)$, Lagrange interpolation in $\mathbb{F}_p[x]_{\le t-1}$ gives $q = \sum_i q(a_i)L_i$, and $s = q(0)$. (2) Given $t - 1$ indices $a_1, \dots, a_{t-1}$, all nonzero, and a candidate s', interpolate at the t distinct points $0, a_1, \dots, a_{t-1}$ with the values $s', q(a_1), \dots, q(a_{t-1})$: there is exactly one polynomial of degree at most $t - 1$ doing this. So, given what the $t - 1$ people hold, each candidate secret is compatible with exactly one choice of $c_1, \dots, c_{t-1}$; since these are chosen uniformly at random, the shares make no value of the secret more likely than any other. □

Exercise 11.12.17. Let $f : V \to W$ be linear, $U \subseteq V$ and $U' \subseteq W$ subspaces. Show that

$$f^{-1}(f(U)) = U + \ker f, \qquad f(f^{-1}(U')) = U' \cap \operatorname{im} f,$$

that f^{-1} preserves sums only up to inclusion, $f^{-1}(U_1') + f^{-1}(U_2') \subseteq f^{-1}(U_1' + U_2')$, and that $f(U_1 + U_2) = f(U_1) + f(U_2)$ and $f^{-1}(U_1' \cap U_2') = f^{-1}(U_1') \cap f^{-1}(U_2')$. If V is finite-dimensional, show that $\dim f(U) = \dim U - \dim(U \cap \ker f)$. Give an example where the inclusion for f^{-1} of a sum is strict.

Solution. If $f(v) = f(u)$ with $u \in U$, then $v = u + (v - u)$ with $v - u \in \ker f$; conversely $f(u + k) = f(u)$ for $k \in \ker f$. This gives the first identity. For the second, $f(f^{-1}(U'))$ consists of the $f(v)$ that lie in U', that is, of the elements of U' that are values of f. Linearity gives

$f(u_1+u_2) = f(u_1)+f(u_2)$, hence $f(U_1+U_2) = f(U_1)+f(U_2)$, and $f(v_1+v_2) = f(v_1)+f(v_2) \in U_1' + U_2'$ if $f(v_i) \in U_i'$, which is the inclusion. The statement for intersections holds for preimages under any map of sets. The dimension formula is rank–nullity (Theorem 11.2.6) for the restriction $f|_U : U \to W$, whose kernel is $U \cap \ker f$ and whose image is $f(U)$. For a strict inclusion, take $f : \mathbb{R} \to \mathbb{R}^2$, $f(t) = (t,t)$, and the two coordinate axes U_1', U_2': their preimages are 0, but $U_1' + U_2' = \mathbb{R}^2$ has preimage $\mathbb{R}$. □

Chapter 12

Multilinear Algebra

12.1 Introduction

This chapter constructs the tensor, symmetric and exterior algebras of a vector space, introduces the tensors of type (r, s) of geometry and physics with their components, contractions and the raising and lowering of indices, and studies the structures that underlie differential forms: alternating forms and interior products, the Pfaffian of a skew-symmetric matrix, orientations, the Hodge star operator of an inner product space, and the decomposition of the exterior algebra of a real vector space with a complex structure into forms of type (p, q). These are the pointwise versions of the constructions of Chapters 36, 40 and 44.

References are [Lan02, Chapters XVI and XIX] and [Gre78].

Prerequisites. Chapter 8 (Rings and Modules) and Chapter 11 (Linear Algebra).

On the way to the Hodge conjecture. The whole chapter is needed: tensor products, tensors of type (r, s) and contraction, the exterior algebra, alternating forms, the Hodge star and forms of type (p, q) are the algebra underlying differential forms and the Hodge decomposition.

Throughout, k is a field, vector spaces are over k and $\otimes = \otimes_k$. Tensor products were defined in Section 8.9.

12.2 Tensor products of vector spaces

Proposition 12.2.1. *Let $(v_i)_{i\in I}$ be a basis of V and $(w_j)_{j\in J}$ a basis of W. Then $(v_i \otimes w_j)$ is a basis of $V \otimes W$; in particular $\dim(V \otimes W) = \dim V \cdot \dim W$. For vector spaces $V_1, \dots, V_n, U$, multilinear maps $V_1 \times \cdots \times V_n \to U$ correspond bijectively to linear maps $V_1 \otimes \cdots \otimes V_n \to U$.*

Proof. $V \cong k^{(I)}$ and $W \cong k^{(J)}$, and by Proposition 8.9.3 $k^{(I)} \otimes k^{(J)} \cong \bigoplus_i (k \otimes k^{(J)}) \cong k^{(I\times J)}$, with $e_i \otimes e_j \mapsto e_{(i,j)}$. The second statement follows by induction from the definition of the tensor product and the associativity isomorphism. □

Proposition 12.2.2. *The linear map $V^* \otimes W \to \mathrm{Hom}_k(V, W)$, $\varphi \otimes w \mapsto (v \mapsto \varphi(v)w)$, is injective, with image the maps of finite rank; it is an isomorphism if V or W is finite-dimensional. For finite-dimensional V, W the map $V^* \otimes W^* \to (V \otimes W)^*$, $\varphi \otimes \psi \mapsto (v \otimes w \mapsto \varphi(v)\psi(w))$, is an isomorphism. Under $V^* \otimes V \cong \mathrm{End}(V)$, the* contraction *$\varphi \otimes v \mapsto \varphi(v)$ is the trace.*

Proof. Let (w_j) be a basis of W. An element of $V^* \otimes W$ is uniquely $\sum_j \varphi_j \otimes w_j$ with finitely many nonzero φ_j (Proposition 12.2.1 applied to a basis of V^*); it maps to $v \mapsto \sum_j \varphi_j(v)w_j$, which is zero only if all $\varphi_j = 0$. The image consists of maps with image in a finite-dimensional subspace, and every such map is of this form (choose a basis of W extending a basis of a finite-dimensional subspace containing the image). If V is finite-dimensional, every map has

finite rank; if W is, likewise. For the second isomorphism, compare dual bases. Finally, with a basis (e_i) of V, $e_i^* \otimes e_j$ corresponds to the matrix unit E_{ji}, whose trace is $\delta_{ij} = e_i^*(e_j)$. □

Counterexample 12.2.3. Not every element of $V \otimes W$ is of the form $v \otimes w$. Under $k^2 \otimes k^2 \cong M_2(k)$ (sending $e_i \otimes e_j$ to the matrix unit E_{ij}), the element $v \otimes w$ corresponds to a matrix of rank at most 1, while $e_1 \otimes e_1 + e_2 \otimes e_2$ corresponds to the identity matrix, of rank 2.

12.3 The tensor, symmetric and exterior algebras

Definition 12.3.1. The *tensor algebra* of V is the graded k-algebra $T(V) = \bigoplus_{n \geq 0} T^n(V)$, with $T^0(V) = k$, $T^n(V) = V^{\otimes n}$, and multiplication induced by $(v_1 \otimes \cdots \otimes v_p)(w_1 \otimes \cdots \otimes w_q) = v_1 \otimes \cdots \otimes v_p \otimes w_1 \otimes \cdots \otimes w_q$. The *symmetric algebra* is $S(V) = T(V)/I_S$, where I_S is the two-sided ideal generated by the elements $v \otimes w - w \otimes v$, and the *exterior algebra* is $\Lambda(V) = T(V)/I_\Lambda$, where I_Λ is generated by the elements $v \otimes v$. The ideals are homogeneous, so both quotients are graded: $S(V) = \bigoplus_n S^n(V)$ and $\Lambda(V) = \bigoplus_n \Lambda^n(V)$. We write $v_1 \cdots v_n$ for the image of $v_1 \otimes \cdots \otimes v_n$ in $S(V)$ and $v_1 \wedge \cdots \wedge v_n$ for its image in $\Lambda(V)$.

Proposition 12.3.2. *Let A be an associative k-algebra and $f : V \to A$ linear.*

1. *f extends uniquely to an algebra homomorphism $T(V) \to A$.*
2. *If A is commutative, it extends uniquely to $S(V) \to A$.*
3. *If $f(v)^2 = 0$ for all $v \in V$, it extends uniquely to $\Lambda(V) \to A$.*

Moreover, n-linear maps $V^n \to U$ that are symmetric (respectively alternating) correspond to linear maps $S^n(V) \to U$ (respectively $\Lambda^n(V) \to U$).

Proof. (1) The n-linear map $(v_1, \ldots, v_n) \mapsto f(v_1) \cdots f(v_n)$ induces $T^n(V) \to A$, and the sum of these is an algebra homomorphism; it is unique since V generates $T(V)$. (2), (3) The homomorphism of (1) kills the generators of I_S, respectively I_Λ.

For the last statement, the degree-n part of I_Λ is spanned by the tensors $x \otimes v \otimes v \otimes y$ with x, y pure tensors, and similarly for I_S. A multilinear $\beta : V^n \to U$ vanishes on the tensors with two equal adjacent factors if and only if it is alternating: expanding $\beta(\ldots, v+w, v+w, \ldots) = 0$ shows it changes sign under adjacent transpositions, hence under all transpositions up to sign, so it vanishes whenever any two arguments are equal. The symmetric case is analogous. □

Proposition 12.3.3. *1. In $\Lambda(V)$, $v \wedge w = -w \wedge v$ for $v, w \in V$, and $\alpha \wedge \beta = (-1)^{pq} \beta \wedge \alpha$ for $\alpha \in \Lambda^p(V)$, $\beta \in \Lambda^q(V)$.*

2. *$S(V)$ is commutative. If $(e_1, \ldots, e_n)$ is a basis of V, then $S(V) \cong k[x_1, \ldots, x_n]$ with $e_i \mapsto x_i$, and $S^d(V)$ corresponds to the homogeneous polynomials of degree d.*
3. *If $(e_1, \ldots, e_n)$ is a basis of V, the elements $e_I = e_{i_1} \wedge \cdots \wedge e_{i_p}$, for $I = \{i_1 < \cdots < i_p\} \subseteq \{1, \ldots, n\}$, form a basis of $\Lambda^p(V)$. So $\dim \Lambda^p(V) = \binom{n}{p}$, $\Lambda^p(V) = 0$ for $p > n$, and $\dim \Lambda(V) = 2^n$.*
4. *Vectors $v_1, \ldots, v_p$ are linearly independent if and only if $v_1 \wedge \cdots \wedge v_p \neq 0$.*
5. *For $f : V \to W$ linear there are induced maps $\Lambda^p f : \Lambda^p V \to \Lambda^p W$, $v_1 \wedge \cdots \wedge v_p \mapsto f(v_1) \wedge \cdots \wedge f(v_p)$, and if $\dim V = n$, $\Lambda^n f$ is multiplication by $\det f$ for $f : V \to V$.*

Proof. (1) $0=(v+w)\wedge(v+w)=v\wedge w+w\wedge v$. Moving each of the q factors of a decomposable β past the p factors of α gives pq sign changes.

(2) Commutativity holds on generators. The two universal properties (Proposition 12.3.2(2) and Proposition 8.6.3) give inverse homomorphisms.

(3) By (1) and $e_i\wedge e_i=0$, the e_I span $\Lambda^p(V)$. For independence, fix I and consider the map $V^p\to k$, $(v_1,\dots,v_p)\mapsto \det(e^*_{i_a}(v_b))_{a,b}$. It is multilinear and alternating by Theorem 11.5.2, so it induces $\varphi_I\colon \Lambda^p(V)\to k$, and $\varphi_I(e_J)=\delta_{IJ}$. A relation $\sum_J c_J e_J=0$ gives $c_I=0$ after applying φ_I.

(4) If $v_1=\sum_{i\geq 2}c_iv_i$, the product vanishes by (1) and $v_i\wedge v_i=0$. If they are independent, extend them to a basis and use (3).

(5) The map exists by the universal property. For $V=W$ of dimension n with basis (e_i), $(v_1,\dots,v_n)\mapsto$ the coefficient of $f(v_1)\wedge\cdots\wedge f(v_n)$ on $e_1\wedge\cdots\wedge e_n$ is multilinear alternating; by Theorem 11.5.2 applied to the columns of the matrix of f, $f(e_1)\wedge\cdots\wedge f(e_n)=\det(f)\,e_1\wedge\cdots\wedge e_n$. □

Proposition 12.3.4. *Let $f\colon V\to W$ be linear with matrix $A=(a_{ij})$ in bases $(e_1,\dots,e_m)$ of V and $(e'_1,\dots,e'_n)$ of W. For subsets $I\subseteq\{1,\dots,n\}$, $J\subseteq\{1,\dots,m\}$ of size p, let $A_{I,J}$ be the $p\times p$ submatrix with rows I and columns J.*

1. *The matrix of $\Lambda^p f$ in the bases (e_J) and (e'_I) is $(\det A_{I,J})_{I,J}$: $\Lambda^p f(e_J)=\sum_I\det(A_{I,J})\,e'_I$.*
2. *(Cauchy–Binet) For an $n\times m$ matrix A and an $m\times n$ matrix B, $\det(AB)=\sum_S \det A_{\{1..n\},S}\det B_{S,\{1..n\}}$, the sum over the subsets $S\subseteq\{1,\dots,m\}$ of size n; in particular $\det(AB)=0$ if $m<n$, and $\det(AB)=\det A\det B$ if $m=n$.*
3. *The rank of f is the largest p with $\Lambda^p f\neq 0$, that is, the largest size of a nonzero minor of A.*

Proof. (1) $\Lambda^p f(e_J)=f(e_{j_1})\wedge\cdots\wedge f(e_{j_p})$, and its coefficient on e'_I is obtained by applying the functional φ_I of the proof of Proposition 12.3.3(3), which gives $\det(e'^*_{i_a}(f(e_{j_b})))_{a,b}=\det(a_{i_a j_b})=\det A_{I,J}$.

(2) By functoriality $\Lambda^n(AB)=\Lambda^nA\circ\Lambda^nB$ on $\Lambda^n(k^n)$, which is one-dimensional with basis $e_{\{1..n\}}$, and $\Lambda^n(AB)$ is multiplication by $\det(AB)$ (Proposition 12.3.3(5)). By (1), $\Lambda^nB(e_{\{1..n\}})=\sum_S\det B_{S,\{1..n\}}e_S$ and $\Lambda^nA(e_S)=\det A_{\{1..n\},S}\,e_{\{1..n\}}$. If $m<n$ there are no such S.

(3) The image of $\Lambda^p f$ is spanned by the products $f(v_1)\wedge\cdots\wedge f(v_p)$, so it is the image of $\Lambda^p(\operatorname{im} f)\to\Lambda^pW$, which is injective because a basis of $\operatorname{im} f$ extends to a basis of W and Proposition 12.3.3(3) applies to both. So $\Lambda^p f\neq 0$ if and only if $\Lambda^p(\operatorname{im} f)\neq 0$, that is, $p\leq\operatorname{rank} f$. Combine with (1). □

Counterexample 12.3.5. In characteristic 2 symmetric and alternating notions separate. Let $k=\mathbb{F}_2$ and $V=k$. The bilinear form $B(x,y)=xy$ satisfies $B(y,x)=B(x,y)=-B(x,y)$, so it is both symmetric and antisymmetric, but it is not alternating, since $B(1,1)=1$; so it does not factor through $\Lambda^2V=0$. Similarly the symmetrisation $S^2V\to V\otimes V$, $vw\mapsto v\otimes w+w\otimes v$, sends the generator e^2 of S^2V to $2\,e\otimes e=0$, so it is not injective. Factorials cause the same phenomena elsewhere: in Proposition 12.5.7 the characteristic enters through the factor $m!$ in $\omega^m=m!\,e^*_1\wedge f^*_1\wedge\cdots\wedge e^*_m\wedge f^*_m$, which vanishes in characteristic $p\leq m$.

12.4 Tensors of type (r,s)

The word *tensor* is used in two related ways. In algebra a tensor is any element of a tensor product. In geometry and physics a tensor is a multilinear quantity attached to a single vector space V (in geometry, the tangent space at a point), with a certain number of slots for vectors and a certain number of slots for linear forms: an inner product eats two vectors and

returns a number, an endomorphism eats a vector and returns a vector, the curvature of a Riemannian manifold eats three vectors and returns a vector. Older texts, and most physics texts, take yet another point of view: a tensor is an array of numbers, one for each choice of basis, which changes in a prescribed way when the basis is changed. This section explains why the three points of view agree, and introduces the operations on tensors (tensor product, contraction, raising and lowering of indices) that are used constantly in differential geometry.

In this section V has finite dimension n, and $(e_1, \dots, e_n)$ is a basis of V. Following the custom of differential geometry, we write $e^i = e_i^*$ for the dual basis of V^* (Definition 11.4.1), so that $e^i(e_j) = \delta^i_j$, where δ^i_j is 1 if $i = j$ and 0 otherwise. Indices of basis vectors of V are written below and indices of basis vectors of V^* above; the reason for this convention will appear in Proposition 12.4.4.

Definition 12.4.1. Let $r, s \in \mathbb{N}$. A *tensor of type* (r, s) on V is an element of

$$T^r_s(V) = \underbrace{V \otimes \cdots \otimes V}_{r} \otimes \underbrace{V^* \otimes \cdots \otimes V^*}_{s} = V^{\otimes r} \otimes (V^*)^{\otimes s},$$

with the convention $T^0_0(V) = k$. One says that such a tensor is r *times contravariant* and s *times covariant*. The *tensor product* of $S = v_1 \otimes \cdots \otimes v_r \otimes \varphi^1 \otimes \cdots \otimes \varphi^s \in T^r_s(V)$ and $S' = v'_1 \otimes \cdots \otimes v'_{r'} \otimes \psi^1 \otimes \cdots \otimes \psi^{s'} \in T^{r'}_{s'}(V)$ is

$$S \otimes S' = v_1 \otimes \cdots \otimes v_r \otimes v'_1 \otimes \cdots \otimes v'_{r'} \otimes \varphi^1 \otimes \cdots \otimes \varphi^s \otimes \psi^1 \otimes \cdots \otimes \psi^{s'} \in T^{r+r'}_{s+s'}(V),$$

extended bilinearly; that is, it is the tensor product of Section 12.2 followed by the isomorphism that moves the factors V in front of the factors V^*.

The tensor product of tensors is well defined: the expression on the right is multilinear in the $r + s + r' + s'$ vectors and forms, so it induces a bilinear map $T^r_s(V) \times T^{r'}_{s'}(V) \to T^{r+r'}_{s+s'}(V)$ by Proposition 12.2.1. It is associative, and it is not commutative: for $v, w \in V$ independent, $v \otimes w \neq w \otimes v$ in $T^2_0(V)$ (Proposition 12.2.1). The small cases are familiar: $T^0_0(V) = k$ consists of scalars, $T^1_0(V) = V$ of vectors and $T^0_1(V) = V^*$ of linear forms, also called *covectors*. The next proposition identifies the others with multilinear maps.

Proposition 12.4.2. *1. There is a unique isomorphism from $T^r_s(V)$ to the space of multilinear maps $(V^*)^r \times V^s \to k$ sending $v_1 \otimes \cdots \otimes v_r \otimes \varphi^1 \otimes \cdots \otimes \varphi^s$ to the map*

$$(\psi^1, \dots, \psi^r, w_1, \dots, w_s) \longmapsto \psi^1(v_1) \cdots \psi^r(v_r)\, \varphi^1(w_1) \cdots \varphi^s(w_s).$$

2. There is a unique isomorphism from $T^1_s(V)$ to the space of multilinear maps $V^s \to V$ sending $v \otimes \varphi^1 \otimes \cdots \otimes \varphi^s$ to the map $(w_1, \dots, w_s) \mapsto \varphi^1(w_1) \cdots \varphi^s(w_s)\, v$. For $s = 1$ this is the isomorphism $T^1_1(V) \cong \mathrm{End}(V)$ of Proposition 12.2.2.

3. The tensors $e_{i_1} \otimes \cdots \otimes e_{i_r} \otimes e^{j_1} \otimes \cdots \otimes e^{j_s}$, for all $i_1, \dots, i_r, j_1, \dots, j_s \in \{1, \dots, n\}$, form a basis of $T^r_s(V)$. In particular $\dim T^r_s(V) = n^{r+s}$.

Proof. (3) The e^j form a basis of V^* (Proposition 11.4.2), and Proposition 12.2.1, applied $r + s - 1$ times, says that the tensor products of basis vectors of the factors form a basis of the tensor product.

(1) By Proposition 12.2.1, multilinear maps $(V^*)^r \times V^s \to k$ are the same as linear maps $(V^*)^{\otimes r} \otimes V^{\otimes s} \to k$, that is, elements of U^* with $U = (V^*)^{\otimes r} \otimes V^{\otimes s}$. Both $T^r_s(V)$ and U^* have dimension n^{r+s}, by (3) and Proposition 11.4.2. The prescribed map exists, because the displayed expression is multilinear in $(v_1, \dots, v_r, \varphi^1, \dots, \varphi^s)$, and it is unique, because the

decomposable tensors span $T^r_s(V)$. It sends the basis vector $e_{i_1} \otimes \cdots \otimes e_{i_r} \otimes e^{j_1} \otimes \cdots \otimes e^{j_s}$ to the linear form on U that takes the value 1 on $e^{i_1} \otimes \cdots \otimes e^{i_r} \otimes e_{j_1} \otimes \cdots \otimes e_{j_s}$ and 0 on the other basis vectors of U of the same kind. These linear forms are the dual basis of the basis of U given by (3) (with the roles of V and V^* exchanged), so the map sends a basis to a basis and is an isomorphism.

(2) The same argument applies: multilinear maps $V^s \to V$ are linear maps $V^{\otimes s} \to V$, a space of dimension $n^s \cdot n = \dim T^1_s(V)$; the prescribed map exists and is unique as in (1), and it sends $e_i \otimes e^{j_1} \otimes \cdots \otimes e^{j_s}$ to the linear map $V^{\otimes s} \to V$ that sends $e_{j_1} \otimes \cdots \otimes e_{j_s}$ to e_i and the other basis vectors $e_{l_1} \otimes \cdots \otimes e_{l_s}$ to 0. These maps form a basis of $\mathrm{Hom}(V^{\otimes s}, V)$ (they are the matrix units in the bases given by (3)), so the map is an isomorphism. For $s = 1$ it sends $v \otimes \varphi$ to $w \mapsto \varphi(w)v$, which is the map of Proposition 12.2.2 composed with the exchange of factors $V \otimes V^* \cong V^* \otimes V$. □

From now on we identify a tensor of type (r, s) with the corresponding multilinear map of (1), and a tensor of type $(1, s)$ also with the multilinear map $V^s \to V$ of (2); the two are related by $T(\psi, w_1, \ldots, w_s) = \psi(T(w_1, \ldots, w_s))$, as one checks on decomposable tensors. So a bilinear form on V is the same as a tensor of type $(0, 2)$, and an endomorphism the same as a tensor of type $(1, 1)$.

Definition 12.4.3. The *components* of $T \in T^r_s(V)$ in the basis (e_i) are the numbers

$$T^{i_1 \ldots i_r}_{j_1 \ldots j_s} = T(e^{i_1}, \ldots, e^{i_r}, e_{j_1}, \ldots, e_{j_s}),$$

so that, by Proposition 12.4.2,

$$T = \sum_{i_1, \ldots, i_r, j_1, \ldots, j_s} T^{i_1 \ldots i_r}_{j_1 \ldots j_s}\, e_{i_1} \otimes \cdots \otimes e_{i_r} \otimes e^{j_1} \otimes \cdots \otimes e^{j_s}.$$

The second formula holds because both sides take the same value on every tuple $(e^{i_1}, \ldots, e^{i_r}, e_{j_1}, \ldots, e_{j_s})$ of basis vectors, and a multilinear map is determined by these values. The components of a vector $v = \sum_i v^i e_i$ are its coordinates $v^i = e^i(v)$, with the index up; those of a linear form $\varphi = \sum_j \varphi_j e^j$ are $\varphi_j = \varphi(e_j)$, with the index down. The components of an endomorphism A, viewed as a tensor of type $(1, 1)$, are $A^i_j = e^i(Ae_j)$, the entries of its matrix (row i, column j); the components of a bilinear form B are $B_{ij} = B(e_i, e_j)$, the entries of its Gram matrix (Definition 11.9.1).

Proposition 12.4.4 (Transformation law)**.** *Let $(e'_1, \ldots, e'_n)$ be a second basis of V, with $e'_j = \sum_i P^i_j e_i$ for an invertible matrix $P = (P^i_j)$ (row i, column j), and let $Q = (Q^i_j) = P^{-1}$.*

1. *The dual bases are related by $e'^j = \sum_i Q^j_i e^i$, and the coordinates of a vector by $v'^i = \sum_j Q^i_j v^j$.*

2. *The components of $T \in T^r_s(V)$ in the two bases are related by*

$$T'^{\,i_1 \ldots i_r}_{j_1 \ldots j_s} = \sum_{k_1, \ldots, k_r, l_1, \ldots, l_s} Q^{i_1}_{k_1} \cdots Q^{i_r}_{k_r}\, P^{l_1}_{j_1} \cdots P^{l_s}_{j_s}\, T^{k_1 \ldots k_r}_{l_1 \ldots l_s}.$$

3. *Conversely, suppose that to every basis $\mathbf{e}$ of V there is assigned a family of numbers $T(\mathbf{e})^{i_1 \ldots i_r}_{j_1 \ldots j_s}$, such that the families assigned to any two bases are related by the formula of (2). Then there is a unique $T \in T^r_s(V)$ whose components in every basis $\mathbf{e}$ are the numbers $T(\mathbf{e})^{i_1 \ldots i_r}_{j_1 \ldots j_s}$.*

Proof. (1) The linear form $\sum_i Q^j_i e^i$ takes on e'_m the value $\sum_i Q^j_i e^i\big(\sum_l P^l_m e_l\big) = \sum_i Q^j_i P^i_m = (QP)^j_m = \delta^j_m$, so it is the j-th vector of the dual basis of (e'_m). Hence $v'^i = e'^i(v) = \sum_j Q^i_j e^j(v) = \sum_j Q^i_j v^j$.

(2) By definition and (1),

$$T'^{\,i_1\dots i_r}_{j_1\dots j_s} = T\Big(\sum_{k_1} Q^{i_1}_{k_1} e^{k_1}, \dots, \sum_{k_r} Q^{i_r}_{k_r} e^{k_r}, \sum_{l_1} P^{l_1}_{j_1} e_{l_1}, \dots, \sum_{l_s} P^{l_s}_{j_s} e_{l_s}\Big),$$

and expanding by multilinearity gives the formula.

(3) Uniqueness holds because a tensor is determined by its components in one basis (Definition 12.4.3). For existence, fix a basis $\mathbf{e}$ and let T be the tensor with components $T(\mathbf{e})^{i_1\dots i_r}_{j_1\dots j_s}$ in $\mathbf{e}$. For another basis $\mathbf{e}'$, the components of T in $\mathbf{e}'$ are obtained from those in $\mathbf{e}$ by the formula of (2), and so are the numbers $T(\mathbf{e}')$ by hypothesis; so they agree. □

Part (3) is the justification of the physicists' definition, "a tensor is something that transforms like a tensor". Part (1) explains the names. The basis vectors change by P; the coordinates of a vector change by the inverse matrix Q, against the basis, and are called *contravariant*; the components of a linear form, $\varphi'_j = \varphi(e'_j) = \sum_l P^l_j \varphi_l$, change by P, together with the basis, and are called *covariant*. A tensor of type (r, s) has r indices of the first kind, written above, and s of the second kind, written below. (These traditional names clash with the language of categories: $V \mapsto V$ is a covariant functor and $V \mapsto V^*$ a contravariant one, Example 6.5.5, while vectors are called contravariant. The physicists' names refer to the components, not to the spaces.)

Example 12.4.5. Let us compare the transformation laws of an endomorphism and of a bilinear form; in both cases the components form an $n \times n$ matrix.

1. For an endomorphism A, a tensor of type $(1,1)$, the formula of Proposition 12.4.4 reads $A'^{\,i}_j = \sum_{k,l} Q^i_k A^k_l P^l_j$, that is, $A' = P^{-1}AP$: the matrix changes by *similarity*, as in Chapter 11. Similar matrices have the same eigenvalues, trace and determinant, so these are invariants of the endomorphism.

2. For a bilinear form B, a tensor of type $(0,2)$, the formula reads $B'_{ij} = \sum_{k,l} P^k_i P^l_j B_{kl}$, that is, $B' = P^T B P$: the Gram matrix changes by *congruence*, as in Definition 11.9.1. Congruent matrices need not have the same eigenvalues: for $B = I$ and $P = 2I$, $P^T B P = 4I$. So "the eigenvalues of a bilinear form" make no sense; what survives for real symmetric forms is the signature (Theorem 11.9.5).

The same matrix can therefore mean two different things, and only the position of the indices tells which. With an inner product the two can be converted into each other (Definition 12.4.10 below), and if both bases are orthonormal for an inner product on a real vector space, then P is orthogonal, $P^{-1} = P^T$, and the two transformation laws coincide.

Example 12.4.6.

1. The identity of V is the tensor $\sum_i e_i \otimes e^i$ of type $(1,1)$; its components are δ^i_j in every basis, as the transformation law confirms: $\sum_{k,l} Q^i_k \delta^k_l P^l_j = (QP)^i_j = \delta^i_j$. Hence $\sum_i e_i \otimes e^i$ does not depend on the basis, which is not obvious from the formula.

2. A bilinear map $\mu\colon V \times V \to V$, for instance the multiplication of a finite-dimensional algebra or the bracket of a Lie algebra, is a tensor of type $(1,2)$. Its components $c^k_{ij} = e^k(\mu(e_i, e_j))$, defined by $\mu(e_i, e_j) = \sum_k c^k_{ij} e_k$, are the *structure constants* of the algebra.

3. The determinant in the basis (e_i), the alternating form $(w_1, \dots, w_n) \mapsto \det(e^i(w_j))$, is a tensor of type $(0, n)$. More generally, alternating forms of degree p are the tensors of type $(0, p)$ that change sign when two arguments are exchanged; Section 12.5 studies them.

4. In Riemannian geometry, the curvature of a Riemannian manifold assigns to each tangent space a tensor of type $(1, 3)$, $(X, Y, Z) \mapsto R(X, Y)Z$, and its *Ricci tensor*, of type $(0, 2)$, is obtained from it by a contraction (Chapter 40).

The most important operation on tensors, after the tensor product, generalises the trace of an endomorphism: a vector slot and a covector slot are paired with each other.

Definition 12.4.7. Let $r, s \geq 1$, $1 \leq a \leq r$ and $1 \leq b \leq s$. The *contraction* of the a-th upper index with the b-th lower index is the linear map $C^a_b \colon T^r_s(V) \to T^{r-1}_{s-1}(V)$ given by

$$C^a_b(v_1 \otimes \cdots \otimes v_r \otimes \varphi^1 \otimes \cdots \otimes \varphi^s) = \varphi^b(v_a)\; v_1 \otimes \cdots \widehat{v_a} \cdots \otimes v_r \otimes \varphi^1 \otimes \cdots \widehat{\varphi^b} \cdots \otimes \varphi^s,$$

where the hat means that the factor is omitted.

The map exists and is unique by Proposition 12.2.1, since the right-hand side is multilinear in $(v_1, \dots, v_r, \varphi^1, \dots, \varphi^s)$. Note that no basis is used in the definition.

Proposition 12.4.8. *1. In components, contraction is summation over a repeated index:*

$$(C^a_b T)^{i_1 \dots \widehat{i_a} \dots i_r}_{j_1 \dots \widehat{j_b} \dots j_s} = \sum_{m=1}^{n} T^{i_1 \dots m \dots i_r}_{j_1 \dots m \dots j_s},$$

with m in the a-th upper and the b-th lower position.

2. *For $r = s = 1$, $C^1_1 \colon \operatorname{End}(V) = T^1_1(V) \to k$ is the trace.*

3. *For $T \in T^1_2(V)$, viewed as a bilinear map $V \times V \to V$, the contraction $C^1_1 T \in T^0_1(V) = V^*$ is the linear form $w \mapsto \operatorname{tr}\big(v \mapsto T(v, w)\big)$.*

Proof. (1) Both sides are linear in T, so it suffices to check the formula for a basis vector $T = e_{k_1} \otimes \cdots \otimes e_{k_r} \otimes e^{l_1} \otimes \cdots \otimes e^{l_s}$, whose components are $T^{i_1 \dots i_r}_{j_1 \dots j_s} = \delta^{i_1}_{k_1} \cdots \delta^{i_r}_{k_r} \delta^{l_1}_{j_1} \cdots \delta^{l_s}_{j_s}$. By definition $C^a_b T = e^{l_b}(e_{k_a})$ times the tensor with the a-th and b-th factors removed, and $e^{l_b}(e_{k_a}) = \delta^{l_b}_{k_a} = \sum_m \delta^m_{k_a} \delta^{l_b}_m$. Comparing components gives the formula.

(2) By (1), $C^1_1 A = \sum_m A^m_m$, the sum of the diagonal entries of the matrix of A (Definition 12.4.3), which is the trace. Alternatively, this is the last statement of Proposition 12.2.2.

(3) By (1), $(C^1_1 T)_j = \sum_m T^m_{mj}$. For fixed $w = e_j$ the endomorphism $v \mapsto T(v, e_j)$ has matrix entries $e^i(T(e_l, e_j)) = T^i_{lj}$, so its trace is $\sum_m T^m_{mj}$. □

Remark 12.4.9. Formulas with components contain many sums over indices that occur once above and once below, as in Propositions 12.4.4 and 12.4.8. Physicists and many geometers use the *Einstein summation convention*: an index that appears once as an upper and once as a lower index is summed over, and the summation sign is omitted. Thus $v = v^i e_i$, $A'^i_j = Q^i_k A^k_l P^l_j$, and the trace of A is A^i_i. The convention has a built-in check: in a correct formula every index that is not summed over appears in the same position on both sides, and each summed index appears exactly once up and once down. A formula such as $\sum_i v^i v^i$, which is not of this form, is not invariant under change of basis; it becomes invariant only once a bilinear form is used to lower one of the indices, as in $\sum_{i,j} g_{ij} v^i v^j$. We do not use the convention in this book.

Let g be a nondegenerate symmetric bilinear form on V (Definition 11.9.1), for instance an inner product when $k = \mathbb{R}$. Its components $g_{ij} = g(e_i, e_j)$ form an invertible symmetric matrix, and we write g^{ij} for the entries of the inverse matrix, so that $\sum_j g^{ij} g_{jl} = \delta^i_l$.

Definition 12.4.10. The isomorphism $\flat\colon V \to V^*, v \mapsto v^\flat = g(v, -)$, and its inverse $\sharp\colon V^* \to V$, $\varphi \mapsto \varphi^\sharp$, are called *lowering* and *raising* of indices. Applying $\flat$ to the a-th factor V of $T^r_s(V)$, and moving the result to the last position, gives an isomorphism $T^r_s(V) \to T^{r-1}_{s+1}(V)$; applying $\sharp$ to a factor V^* gives an isomorphism $T^r_s(V) \to T^{r+1}_{s-1}(V)$. The *trace with respect to* g of a tensor B of type $(0,2)$ is $\operatorname{tr}_g B = C^1_1(B^\sharp)$, the trace of the endomorphism obtained by raising the first index of B.

Proposition 12.4.11. 1. *In components,* $(v^\flat)_i = \sum_j g_{ij} v^j$ *and* $(\varphi^\sharp)^i = \sum_j g^{ij} \varphi_j$.

2. *For B of type $(0,2)$, the endomorphism $B^\sharp$ is characterised by $g(B^\sharp w, v) = B(v, w)$ for all v, w, and* $\operatorname{tr}_g B = \sum_{i,j} g^{ij} B_{ij}$.

3. *If $k = \mathbb{R}$, g is an inner product and (e_i) is orthonormal, then $g_{ij} = g^{ij} = \delta_{ij}$, raising and lowering do not change components, and* $\operatorname{tr}_g B = \sum_i B(e_i, e_i)$.

Proof. (1) $(v^\flat)_i = v^\flat(e_i) = g(v, e_i) = \sum_j v^j g_{ji}$, and $g_{ji} = g_{ij}$. So $\flat$ has matrix (g_{ij}) in the bases (e_i) and (e^i), and its inverse $\sharp$ has matrix (g^{ij}).

(2) Write $B = \sum_{i,j} B_{ij} e^i \otimes e^j$. Raising the first index replaces e^i by $(e^i)^\sharp = \sum_l g^{li} e_l$, so $B^\sharp = \sum_{i,j,l} g^{li} B_{ij}\, e_l \otimes e^j$, the endomorphism $w \mapsto \sum_{i,j,l} g^{li} B_{ij} e^j(w)\, e_l = \sum_i B(e_i, w)(e^i)^\sharp$. Hence $g(B^\sharp w, v) = \sum_i B(e_i, w) e^i(v) = B(v, w)$; this characterises $B^\sharp w$ because g is nondegenerate. By Proposition 12.4.8(1) the trace is $\sum_m (B^\sharp)^m_m = \sum_{m,i} g^{mi} B_{im}$, which is $\sum_{i,j} g^{ij} B_{ij}$ since $g^{mi} = g^{im}$.

(3) The Gram matrix of an orthonormal basis is the identity, which is its own inverse; now apply (1) and (2). □

In particular $\operatorname{tr}_g B$ does not depend on the basis, being a contraction, although the formula $\sum_i B(e_i, e_i)$ is only valid for orthonormal bases. For $B = g$ one finds $\operatorname{tr}_g g = \sum_{i,j} g^{ij} g_{ij} = n$. This is how the Ricci tensor and the scalar curvature of a Riemannian manifold are obtained from its curvature tensor (Chapter 40), and how the Laplacian $\Delta f = \operatorname{tr}_g \operatorname{Hess} f$ is obtained from the Hessian.

Exercise 12.4.12. Assume $\operatorname{char} k \neq 2$. Show that every tensor of type $(0,2)$ is uniquely the sum of a symmetric and an alternating one, and that the symmetric ones form a subspace of dimension $n(n+1)/2$ and the alternating ones a subspace of dimension $n(n-1)/2$. Show that the symmetric ones are preserved by the transformation law, that is, the notion of symmetry does not depend on the basis.

Solution. Write $B = \frac{1}{2}(B + B^t) + \frac{1}{2}(B - B^t)$, where $B^t(v, w) = B(w, v)$; the first summand is symmetric and the second alternating, because $(B - B^t)(v, v) = 0$. If B is both symmetric and alternating, then $0 = B(v + w, v + w) = B(v, w) + B(w, v) = 2B(v, w)$, so $B = 0$; this gives uniqueness. In components, symmetric means $B_{ij} = B_{ji}$, so a symmetric tensor is determined by its components B_{ij} with $i \leq j$, which are arbitrary: dimension $n + \binom{n}{2} = n(n+1)/2$. Alternating means $B_{ij} = -B_{ji}$ and $B_{ii} = 0$, so the components with $i < j$ are free: dimension $\binom{n}{2} = n(n-1)/2$; the two dimensions add up to n^2. Symmetry is defined by the condition $B(v, w) = B(w, v)$ for all v, w, which does not mention a basis; equivalently, if $B^T = B$ then $(P^T B P)^T = P^T B^T P = P^T B P$. □

Exercise 12.4.13. Let $A, B \in \operatorname{End}(V) = T^1_1(V)$, so that $A \otimes B \in T^2_2(V)$. Show that $C^2_1(A \otimes B) = A \circ B$ and that $C^1_1 C^2_1(A \otimes B) = \operatorname{tr}(AB)$, while $C^1_1 C^1_1(A \otimes B) = \operatorname{tr} A \operatorname{tr} B$. Deduce that $\operatorname{tr}(AB) = \operatorname{tr}(BA)$.

Solution. By linearity we may take $A = v \otimes \varphi$ and $B = w \otimes \psi$, so $A \otimes B = v \otimes w \otimes \varphi \otimes \psi$, $A(x) = \varphi(x)v$ and $B(x) = \psi(x)w$. Then $C_1^2(A \otimes B) = \varphi(w)\, v \otimes \psi$, the endomorphism $x \mapsto \varphi(w)\psi(x)v$; and $(A \circ B)(x) = A(\psi(x)w) = \psi(x)\varphi(w)v$, the same. Applying C_1^1, the trace (Proposition 12.4.8(2)), gives $\operatorname{tr}(AB)$, which equals $\varphi(w)\psi(v)$. On the other hand $C_1^1(A \otimes B) = \varphi(v)\, w \otimes \psi$ and then C_1^1 gives $\varphi(v)\psi(w) = \operatorname{tr} A \operatorname{tr} B$. Finally $\operatorname{tr}(BA)$ is computed by the same formula with the roles exchanged, $\psi(v)\varphi(w)$, which is the same number as $\operatorname{tr}(AB) = \varphi(w)\psi(v)$; both sides being bilinear in (A, B), the identity holds for all A, B. □

12.5 Alternating forms

In this section V has finite dimension n.

Proposition 12.5.1. *The pairing $\Lambda^p(V^*) \times \Lambda^p(V) \to k$ determined by $\langle \varphi_1 \wedge \cdots \wedge \varphi_p, v_1 \wedge \cdots \wedge v_p \rangle = \det(\varphi_i(v_j))$ is well defined and perfect. Hence $\Lambda^p(V^*) \cong \Lambda^p(V)^*$, which by Proposition 12.3.2 is the space $\operatorname{Alt}^p(V)$ of alternating p-linear forms on V.*

Proof. The determinant is multilinear and alternating both in the φ_i and in the v_j (using Proposition 11.5.3(2)), so it induces a bilinear pairing. For a basis (e_i) with dual basis (e_i^*), $\langle e_I^*, e_J \rangle = \delta_{IJ}$, so the pairing is perfect. □

Notation 12.5.2. We identify $\Lambda^p(V^*)$ with $\operatorname{Alt}^p(V)$ via Proposition 12.5.1: an element $\alpha \in \Lambda^p(V^*)$ is evaluated on vectors as $\alpha(v_1, \ldots, v_p) = \langle \alpha, v_1 \wedge \cdots \wedge v_p \rangle$. With this convention, $(\varphi_1 \wedge \cdots \wedge \varphi_p)(v_1, \ldots, v_p) = \det(\varphi_i(v_j))$, without a factor $1/p!$.

Example 12.5.3. *The three descriptions of an alternating form, explicitly.* Let $e_1, \ldots, e_n$ be a basis of V with dual basis $e_1^*, \ldots, e_n^*$, and for $I = \{i_1 < \cdots < i_p\}$ write $e_I = e_{i_1} \wedge \cdots \wedge e_{i_p}$ and $e_I^* = e_{i_1}^* \wedge \cdots \wedge e_{i_p}^*$.

1. *From $\Lambda^p(V^*)$ to $\operatorname{Alt}^p(V)$.* An element $\alpha = \sum_I a_I e_I^*$ acts on vectors $v_j = \sum_i v_{ij} e_i$ by $\alpha(v_1, \ldots, v_p) = \sum_I a_I \det(v_{i_k j})_{k,j}$, the sum of the coefficients times the $p \times p$ minors, with rows I, of the matrix of coordinates of the v_j.

2. *From $\operatorname{Alt}^p(V)$ to $\Lambda^p(V^*)$.* An alternating p-linear map A is $\sum_I A(e_{i_1}, \ldots, e_{i_p})\, e_I^*$: the coefficients are the values on increasing tuples of basis vectors. Summing over all tuples instead, $A = \frac{1}{p!} \sum_{i_1, \ldots, i_p} A(e_{i_1}, \ldots, e_{i_p})\, e_{i_1}^* \wedge \cdots \wedge e_{i_p}^*$, since each increasing tuple appears $p!$ times, with the same sign in A and in the wedge product.

3. *As a linear form on $\Lambda^p V$.* α sends e_J to a_J, by Proposition 12.5.1; so (e_I^*) is the dual basis of (e_J).

For instance, on $\mathbb{R}^3$ let $\alpha = e_1^* \wedge e_2^* + 2e_2^* \wedge e_3^*$. As a bilinear map, $\alpha(v, w) = (v_1 w_2 - v_2 w_1) + 2(v_2 w_3 - v_3 w_2) = v^T A w$ with the skew-symmetric matrix A having $A_{12} = 1$, $A_{23} = 2$, $A_{13} = 0$; as a linear form on $\Lambda^2 \mathbb{R}^3$ it sends $e_1 \wedge e_2 \mapsto 1$, $e_2 \wedge e_3 \mapsto 2$, $e_1 \wedge e_3 \mapsto 0$; and under the identification $\Lambda^2 \mathbb{R}^3 \cong \mathbb{R}^3$ of the cross product ($e_2 \wedge e_3 \mapsto e_1$, $e_3 \wedge e_1 \mapsto e_2$, $e_1 \wedge e_2 \mapsto e_3$) it is the vector $(2, 0, 1)$, with $\alpha(v, w) = \langle (2, 0, 1), v \times w \rangle$. For differential forms the same dictionary holds at each point with $e_i^* = dx^i$ and $e_i = \partial_i$: $\omega = \sum_I \omega_I\, dx^I$ with $\omega_I = \omega(\partial_{i_1}, \ldots, \partial_{i_p})$.

Conventions. Some books identify $\Lambda^p(V^*)$ with $\operatorname{Alt}^p(V)$ through the *alternation* map $\operatorname{Alt}(T)(v_1, \ldots, v_p) = \frac{1}{p!} \sum_\sigma \operatorname{sgn}(\sigma) T(v_{\sigma(1)}, \ldots, v_{\sigma(p)})$, which gives $(\varphi_1 \wedge \cdots \wedge \varphi_p)(v_1, \ldots, v_p) = \frac{1}{p!} \det(\varphi_i(v_j))$. In our convention $\varphi_1 \wedge \cdots \wedge \varphi_p = p!\, \operatorname{Alt}(\varphi_1 \otimes \cdots \otimes \varphi_p)$, with no factor in the evaluation; for $p = 2$, $(\varphi \wedge \psi)(v, w) = \varphi(v)\psi(w) - \varphi(w)\psi(v)$ for us, and half of it in the other convention. Formulas such as the invariant formula for d (Chapter 36) change by such factors between books.

Proposition 12.5.4. *For $\alpha \in \Lambda^p(V^*)$ and $\beta \in \Lambda^q(V^*)$,*

$$(\alpha \wedge \beta)(v_1, \dots, v_{p+q}) = \sum_{\sigma} \operatorname{sgn}(\sigma)\, \alpha(v_{\sigma(1)}, \dots, v_{\sigma(p)})\, \beta(v_{\sigma(p+1)}, \dots, v_{\sigma(p+q)}),$$

the sum running over the shuffles*: permutations $\sigma \in S_{p+q}$ with $\sigma(1) < \cdots < \sigma(p)$ and $\sigma(p+1) < \cdots < \sigma(p+q)$.*

Proof. Both sides are bilinear in (α, β), so we may take $\alpha = \varphi_1 \wedge \cdots \wedge \varphi_p$ and $\beta = \varphi_{p+1} \wedge \cdots \wedge \varphi_{p+q}$. The left side is $\det M$ with $M = (\varphi_i(v_j))$. In the Leibniz formula $\det M = \sum_\pi \operatorname{sgn}(\pi) \prod_j M_{\pi(j)j}$, group the permutations π according to the set $A = \{j : \pi(j) \le p\}$ of columns sent to the first p rows. For fixed $A = \{a_1 < \cdots < a_p\}$ with complement $\{b_1 < \cdots < b_q\}$, let σ be the shuffle with $\sigma(i) = a_i$ and $\sigma(p+i) = b_i$. Every such π is uniquely $\pi = (\pi_1 \times \pi_2) \circ \sigma^{-1}$ with $\pi_1 \in S_p$ acting on $\{1, \dots, p\}$ and π_2 on $\{p+1, \dots, p+q\}$, and $\operatorname{sgn}\pi = \operatorname{sgn}\pi_1 \operatorname{sgn}\pi_2 \operatorname{sgn}\sigma$. Summing over π_1 and π_2 gives $\operatorname{sgn}(\sigma) \det(\varphi_i(v_{a_j})) \det(\varphi_{p+i}(v_{b_j}))$, which is the term of σ on the right. □

Definition 12.5.5. For $v \in V$ and $\alpha \in \Lambda^p(V^*)$ with $p \ge 1$, the *interior product* $\iota_v \alpha \in \Lambda^{p-1}(V^*)$ is $(\iota_v\alpha)(v_2, \dots, v_p) = \alpha(v, v_2, \dots, v_p)$; for $p = 0$, $\iota_v \alpha = 0$.

Proposition 12.5.6. *$\iota_v(\alpha \wedge \beta) = \iota_v\alpha \wedge \beta + (-1)^p \alpha \wedge \iota_v\beta$ for $\alpha \in \Lambda^p(V^*)$, and $\iota_v\iota_w = -\iota_w\iota_v$.*

Proof. Expanding the determinant along the first column (Laplace expansion) gives $\iota_v(\varphi_1 \wedge \cdots \wedge \varphi_p) = \sum_{i=1}^{p} (-1)^{i-1} \varphi_i(v)\, \varphi_1 \wedge \cdots \widehat{\varphi_i} \cdots \wedge \varphi_p$. Applying this formula to a product of decomposable forms and splitting the sum according to whether i is among the first p factors gives the first identity. The second holds because $\alpha(w, v, \dots) = -\alpha(v, w, \dots)$. □

Proposition 12.5.7. *Suppose* $\operatorname{char} k = 0$*, and let $\omega \in \Lambda^2(V^*)$ be nondegenerate,* $\dim V = 2m$*. Then $\omega^m = \omega \wedge \cdots \wedge \omega \neq 0$, and every $f \in \mathrm{GL}(V)$ with $\omega(fv, fw) = \omega(v, w)$ has $\det f = 1$.*

Proof. With a symplectic basis (Theorem 11.9.6) and its dual basis, $\omega = \sum_i e_i^* \wedge f_i^*$, as both sides take the same values on pairs of basis vectors. The 2-forms $e_i^* \wedge f_i^*$ commute and square to zero, so $\omega^m = m!\, e_1^* \wedge f_1^* \wedge \cdots \wedge e_m^* \wedge f_m^* \neq 0$. The map $f^* \colon V^* \to V^*$, $\varphi \mapsto \varphi \circ f$, satisfies $(\Lambda^2 f^*)(\omega) = \omega$, hence $(\Lambda^{2m} f^*)(\omega^m) = \omega^m$; but $\Lambda^{2m} f^*$ is multiplication by $\det f^* = \det f$ (Proposition 12.3.3(5) and Proposition 11.4.2(3)). □

The same computation, applied to an arbitrary alternating form instead of a nondegenerate one, produces a square root of the determinant of a skew-symmetric matrix. In the rest of this section k is a field of characteristic 0, $V = k^{2m}$ with standard basis (e_i) and dual basis (e_i^*). To a skew-symmetric matrix $A \in M_{2m}(k)$, that is $A^T = -A$, attach the 2-form

$$\alpha_A = \sum_{i<j} A_{ij}\, e_i^* \wedge e_j^* = \frac{1}{2} \sum_{i,j} A_{ij}\, e_i^* \wedge e_j^* \in \Lambda^2(V^*).$$

The two expressions agree because $A_{ii} = 0$ and $A_{ji}\, e_j^* \wedge e_i^* = A_{ij}\, e_i^* \wedge e_j^*$. As an alternating form (Notation 12.5.2), $\alpha_A(v, w) = \sum_{i<j} A_{ij}(v_i w_j - v_j w_i) = \sum_{i,j} A_{ij} v_i w_j = v^T A w$. Since $\Lambda^{2m}(V^*)$ is one-dimensional, spanned by $e_1^* \wedge \cdots \wedge e_{2m}^*$ (Proposition 12.3.3(3)), the following definition makes sense.

Definition 12.5.8. The *Pfaffian* of a skew-symmetric matrix $A \in M_{2m}(k)$ is the scalar $\operatorname{Pf}(A)$ with

$$\alpha_A^m = \alpha_A \wedge \cdots \wedge \alpha_A = m!\, \operatorname{Pf}(A)\, e_1^* \wedge \cdots \wedge e_{2m}^*.$$

Proposition 12.5.9. *Let $A \in M_{2m}(k)$ be skew-symmetric.*

1. $\mathrm{Pf}(A) = \dfrac{1}{2^m m!} \displaystyle\sum_{\sigma \in S_{2m}} \operatorname{sgn}(\sigma)\, A_{\sigma(1)\sigma(2)} A_{\sigma(3)\sigma(4)} \cdots A_{\sigma(2m-1)\sigma(2m)}$. *So* Pf *is a homogeneous polynomial of degree m in the entries, with* $\mathrm{Pf}(\lambda A) = \lambda^m \mathrm{Pf}(A)$*; for instance*
$$\mathrm{Pf}\begin{pmatrix} 0 & a \\ -a & 0 \end{pmatrix} = a, \qquad \mathrm{Pf}(A) = A_{12}A_{34} - A_{13}A_{24} + A_{14}A_{23} \quad (m = 2).$$
2. $\mathrm{Pf}(g^T A g) = \det(g)\,\mathrm{Pf}(A)$ *for every $g \in M_{2m}(k)$. In particular* Pf *is invariant under conjugation by* $\mathrm{SO}(2m)$*, and changes sign under conjugation by an orthogonal matrix of determinant -1.*
3. *If A is block diagonal with blocks* $\begin{pmatrix} 0 & a_i \\ -a_i & 0 \end{pmatrix}$, $i = 1, \dots, m$, *then* $\mathrm{Pf}(A) = a_1 a_2 \cdots a_m$.
4. $\mathrm{Pf}(A)^2 = \det A$.

Proof. (1) Expanding the m-th power of $\alpha_A = \frac{1}{2}\sum_{i,j} A_{ij} e_i^* \wedge e_j^*$ gives
$$\alpha_A^m = \frac{1}{2^m} \sum_{i_1, j_1, \dots, i_m, j_m} A_{i_1 j_1} \cdots A_{i_m j_m}\, e_{i_1}^* \wedge e_{j_1}^* \wedge \cdots \wedge e_{i_m}^* \wedge e_{j_m}^*.$$
A wedge product of 1-forms with a repeated factor vanishes, so only the terms in which $(i_1, j_1, \dots, i_m, j_m) = (\sigma(1), \dots, \sigma(2m))$ for a permutation σ survive, and for them $e^*_{\sigma(1)} \wedge \cdots \wedge e^*_{\sigma(2m)} = \operatorname{sgn}(\sigma)\, e_1^* \wedge \cdots \wedge e_{2m}^*$ by Proposition 12.3.3(1). Comparing with the definition gives the formula. For $m = 1$ the two permutations give $\frac{1}{2}(A_{12} - A_{21}) = A_{12}$. In general the $2^m m!$ permutations that differ by reordering the m pairs (an even permutation of positions) and by swapping the two entries of some pairs (which changes both $\operatorname{sgn}\sigma$ and the sign of one factor) give the same term, so $\mathrm{Pf}(A)$ is the sum over the ways of splitting $\{1, \dots, 2m\}$ into m pairs $\{a_l < b_l\}$ of $\pm \prod_l A_{a_l b_l}$, the sign being that of the permutation $(a_1, b_1, \dots, a_m, b_m)$. For $m = 2$ the three splittings $\{12, 34\}$, $\{13, 24\}$, $\{14, 23\}$ give the permutations 1234, 1324, 1423, of signs $+1, -1, +1$.

(2) Let $g^*\colon V^* \to V^*$, $\varphi \mapsto \varphi \circ g$, where g acts on $V = k^{2m}$ by matrix multiplication. Then $g^* e_k^* = \sum_i g_{ki} e_i^*$, because $e_k^*(g e_i) = g_{ki}$. The induced map Λg^* on $\Lambda(V^*)$ is multiplicative, and
$$(\Lambda^2 g^*)(\alpha_A) = \frac{1}{2}\sum_{k,l} A_{kl} \Big(\sum_i g_{ki} e_i^*\Big) \wedge \Big(\sum_j g_{lj} e_j^*\Big) = \frac{1}{2}\sum_{i,j} (g^T A g)_{ij}\, e_i^* \wedge e_j^* = \alpha_{g^T A g},$$
$g^T A g$ being again skew-symmetric. Taking m-th powers, $\alpha^m_{g^T A g} = (\Lambda^{2m} g^*)(\alpha_A^m) = m!\,\mathrm{Pf}(A)\det(g)\, e_1^* \wedge \cdots \wedge e_{2m}^*$, since $\Lambda^{2m} g^*$ is multiplication by $\det g^* = \det g$ (Proposition 12.3.3(5) and Proposition 11.4.2(3)). For g orthogonal, $g^T A g = g^{-1} A g$.

(3) Here $\alpha_A = \sum_i a_i\, e^*_{2i-1} \wedge e^*_{2i}$. The 2-forms $e^*_{2i-1} \wedge e^*_{2i}$ commute and square to zero, so $\alpha_A^m = m!\, a_1 \cdots a_m\, e_1^* \wedge \cdots \wedge e_{2m}^*$, as in the proof of Proposition 12.5.7.

(4) Suppose first that A is invertible. Then $\omega(v, w) = v^T A w$ is a nondegenerate alternating form, and by Theorem 11.9.6 it has a symplectic basis $e_1', \dots, e_m', f_1', \dots, f_m'$. Let g be the matrix with columns $e_1', f_1', e_2', f_2', \dots, e_m', f_m'$ (in this order). The entries of $g^T A g$ are the values of ω on pairs of these vectors, so $g^T A g = J$ is block diagonal with blocks $\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. By (3), $\mathrm{Pf}(J) = 1$, and $\det J = 1$. By (2), $\det(g)\mathrm{Pf}(A) = 1$, while $\det(g)^2 \det(A) = \det J = 1$; so $\mathrm{Pf}(A)^2 = \det(g)^{-2} = \det A$. If A is not invertible, choose $v \neq 0$ with $Av = 0$ and an invertible g with first column v. The first column of $g^T A g$ is $g^T A v = 0$, and by skew-symmetry so is its first row; hence $\alpha_{g^T A g}$ is a 2-form in $e_2^*, \dots, e_{2m}^*$ only, and its m-th power, of degree $2m$ in $2m - 1$ linear forms, vanishes. So $\det(g)\mathrm{Pf}(A) = \mathrm{Pf}(g^T A g) = 0$, and $\mathrm{Pf}(A) = 0 = \det A$. □

Since Pf is a polynomial with rational coefficients, the identity in (2) is a polynomial identity in the entries of A and g; so it remains true when the entries of A are taken in any commutative $\mathbb{Q}$-algebra, for instance the algebra of differential forms of even degree on a manifold. This is how the Pfaffian is applied to curvature matrices in Chapter 39, where it produces the Euler form.

Example 12.5.10. For the 4×4 skew-symmetric matrix with $A_{12}=1$, $A_{13}=2$, $A_{14}=3$, $A_{23}=4$, $A_{24}=5$, $A_{34}=6$, the formula gives $\operatorname{Pf}(A)=1\cdot6-2\cdot5+3\cdot4=8$, and indeed $\det A=64$. A real skew-symmetric matrix has $\det A=\operatorname{Pf}(A)^2\geq0$; this explains why the determinant of a skew-symmetric matrix of even size is a perfect square, while one of odd size is 0 (as $\det A=\det A^T=\det(-A)=(-1)^n\det A$).

12.6 Orientations and the Hodge star

Definition 12.6.1. Let V be a real vector space of dimension $n\geq1$. Two ordered bases are *equally oriented* if the change of basis matrix has positive determinant. This is an equivalence relation with two classes, the *orientations* of V; equivalently, an orientation is one of the two components $\{c\,e_1\wedge\cdots\wedge e_n : c>0\}$, $\{c\,e_1\wedge\cdots\wedge e_n : c<0\}$ of $\Lambda^nV\setminus\{0\}$.

Proposition 12.6.2. *Let (V,g) be a real inner product space of dimension n. There is a unique inner product on $\Lambda^p(V)$ with $\langle v_1\wedge\cdots\wedge v_p, w_1\wedge\cdots\wedge w_p\rangle=\det(g(v_i,w_j))$. If (e_i) is orthonormal, the e_I are orthonormal. If V is oriented, the element* $\operatorname{vol}=e_1\wedge\cdots\wedge e_n$ *does not depend on the choice of an oriented orthonormal basis; it is the* volume element.

Proof. The formula is multilinear and alternating in the v_i and in the w_j, so it induces a bilinear form, which is symmetric by Proposition 11.5.3(2). On an orthonormal basis $\langle e_I,e_J\rangle=\delta_{IJ}$, so the form is positive definite. If (f_i) is another oriented orthonormal basis, $f_j=\sum_i a_{ij}e_i$ with $A\in\mathrm{O}(n)$ and $\det A>0$, hence $\det A=1$, and $f_1\wedge\cdots\wedge f_n=\det(A)\,e_1\wedge\cdots\wedge e_n$. □

Theorem 12.6.3. *Let (V,g) be an oriented real inner product space of dimension n. There is a unique linear map $*\colon\Lambda^p(V)\to\Lambda^{n-p}(V)$ with*

$$\alpha\wedge*\beta=\langle\alpha,\beta\rangle\operatorname{vol}\qquad\text{for all }\alpha,\beta\in\Lambda^p(V).$$

For an oriented orthonormal basis, $*e_I=\varepsilon_Ie_{I^c}$ where $e_I\wedge e_{I^c}=\varepsilon_I\operatorname{vol}$, $\varepsilon_I=\pm1$. The map $*$ is an isometry, $**=(-1)^{p(n-p)}$ on $\Lambda^p(V)$, and $\alpha\wedge*\beta=\beta\wedge*\alpha$.

Proof. The pairing $\Lambda^p(V)\times\Lambda^{n-p}(V)\to\Lambda^n(V)=\mathbb{R}\operatorname{vol}$ is perfect, since $e_I\wedge e_J$ is $\pm\operatorname{vol}$ if $J=I^c$ and 0 otherwise. Hence for each β there is a unique $*\beta$ representing the functional $\alpha\mapsto\langle\alpha,\beta\rangle$, and it depends linearly on β. The formula: $e_J\wedge\varepsilon_Ie_{I^c}$ is $\varepsilon_I^2\operatorname{vol}=\operatorname{vol}$ if $J=I$ and 0 otherwise, which is $\langle e_J,e_I\rangle\operatorname{vol}$. So $*$ maps the orthonormal basis (e_I) to $(\pm e_{I^c})$, hence is an isometry. Next, $**e_I=\varepsilon_I\varepsilon_{I^c}e_I$, and $e_{I^c}\wedge e_I=(-1)^{p(n-p)}e_I\wedge e_{I^c}$ by Proposition 12.3.3(1), so $\varepsilon_{I^c}=(-1)^{p(n-p)}\varepsilon_I$. The last identity follows from the symmetry of the inner product. □

Example 12.6.4. On $\mathbb{R}^3$ with the standard orientation, $*e_1=e_2\wedge e_3$, $*e_2=e_3\wedge e_1$, $*e_3=e_1\wedge e_2$, $*1=\operatorname{vol}$ and $*\operatorname{vol}=1$. The map $(v,w)\mapsto*(v\wedge w)$ is the cross product. On $\mathbb{R}^4$, $*$ is an involution of Λ^2 (since $(-1)^{2\cdot2}=1$), which splits into ±1-eigenspaces of dimension 3: the self-dual and anti-self-dual 2-vectors.

The inner product of Proposition 12.6.2 gives a norm $|\xi|$ on p-vectors and, through the pairing of Notation 12.5.2, a norm $|\varphi|$ on p-forms. For the geometry of p-dimensional areas another pair of norms is better adapted: they treat the *simple* p-vectors $v_1\wedge\cdots\wedge v_p$, which represent oriented p-dimensional parallelepipeds, as the basic objects.

Definition 12.6.5. Let (V, g) be a real inner product space and $1 \le p \le \dim V$. A p-vector $\xi \in \Lambda^p(V)$ is *simple* if $\xi = v_1 \wedge \cdots \wedge v_p$ for some $v_i \in V$. The *comass* of a p-form $\varphi \in \Lambda^p(V^*)$ is

$$\|\varphi\| = \sup\{\varphi(\xi) : \xi \text{ simple}, |\xi| = 1\} = \sup\{\varphi(v_1, \dots, v_p) : v_1, \dots, v_p \text{ orthonormal}\},$$

and the *mass* of a p-vector ξ is $\|\xi\| = \sup\{\varphi(\xi) : \|\varphi\| \le 1\}$.

The two descriptions of the comass agree: if $v_1, \dots, v_p$ are linearly independent, Gram–Schmidt (Theorem 11.10.3) replaces them by an orthonormal family $u_1, \dots, u_p$ with $v_1 \wedge \cdots \wedge v_p = c\, u_1 \wedge \cdots \wedge u_p$, $c > 0$, since the change of basis is triangular with positive diagonal; and $|u_1 \wedge \cdots \wedge u_p| = 1$ by Proposition 12.6.2. So the unit simple p-vectors are the $u_1 \wedge \cdots \wedge u_p$ with (u_i) orthonormal: the oriented p-planes of V, each with its unit area element.

Proposition 12.6.6. *Let (V, g) be a real inner product space of dimension n, and $1 \le p \le n$.*

1. *The comass and the mass are norms, and $\|\varphi\| \le |\varphi|$ and $|\xi| \le \|\xi\|$ for all φ and ξ.*
2. *For simple ξ, $\|\xi\| = |\xi|$. For $p = 1$, comass and mass equal the Euclidean norms.*
3. *If $\xi = \xi_1 + \cdots + \xi_m$ with simple ξ_i, then $\|\xi\| \le |\xi_1| + \cdots + |\xi_m|$, and $\varphi(\xi) \le \|\varphi\|\,\|\xi\|$ for all φ and ξ.*

Proof. (1) By Cauchy–Schwarz, with φ identified with an element of $\Lambda^p(V)$ via the inner product, $\varphi(\xi) \le |\varphi||\xi| = |\varphi|$ for unit ξ, so the supremum is finite and $\|\varphi\| \le |\varphi|$. The comass is clearly subadditive and homogeneous, and $\|\varphi\| \ge |\varphi(\xi)|$ for unit simple ξ, as $-\xi$ is also unit simple. So $\|\varphi\| = 0$ forces $\varphi = 0$, since the unit simple vectors include the orthonormal basis (e_I) of $\Lambda^p(V)$, on which φ then vanishes. For $\xi = \sum_I \xi^I e_I$ and $\|\varphi\| \le 1$, $\varphi(\xi) = \sum_I \xi^I \varphi(e_I) \le \sum_I |\xi^I|$, so $\|\xi\|$ is finite; it is subadditive and homogeneous, being a supremum of linear functions of ξ; and $\|\xi\| \ge \varphi(\xi)$ for $\varphi = \xi/|\xi|$, viewed as a form, which has $\|\varphi\| \le |\varphi| = 1$, so $\|\xi\| \ge |\xi|^2/|\xi| = |\xi|$.

(2) For simple $\xi \ne 0$, $\xi/|\xi|$ is a unit simple vector, so $\varphi(\xi) \le \|\varphi\|\,|\xi|$, and taking the supremum over $\|\varphi\| \le 1$ gives $\|\xi\| \le |\xi|$; the reverse is (1). For $p = 1$ every vector is simple, so both definitions reduce to the Euclidean ones.

(3) For $\|\varphi\| \le 1$, $\varphi(\xi) = \sum_i \varphi(\xi_i) \le \sum_i |\xi_i|$ by (2); take the supremum. The second inequality is the definition of the dual norm. □

In fact $\|\xi\|$ is the smallest value of $|\xi_1| + \cdots + |\xi_m|$ over all decompositions of ξ into simple p-vectors [Fed69, 1.8.1]: the mass of a p-vector is its total area, computed as economically as possible from oriented parallelepipeds. By (2), the norms can differ from the Euclidean ones only because of non-simple p-vectors, and the next example shows that they do.

Example 12.6.7. On $\mathbb{R}^4$ with the standard inner product, let $\omega = e^1 \wedge e^2 + e^3 \wedge e^4$ and $\xi = e_1 \wedge e_2 + e_3 \wedge e_4$.

1. $|\omega| = |\xi| = \sqrt{2}$, as e_{12} and e_{34} are orthonormal.
2. $\|\omega\| = 1$. Let $J(u^1, u^2, u^3, u^4) = (-u^2, u^1, -u^4, u^3)$, an isometry. Then $\omega(u, v) = u^1 v^2 - u^2 v^1 + u^3 v^4 - u^4 v^3 = \langle Ju, v\rangle \le |Ju||v| = 1$ for orthonormal u, v, with equality for $v = Ju$, as for $(u, v) = (e_1, e_2)$. (This is the case $n = 2$ of the Wirtinger inequality of Chapter 47: ω is the Kähler form of $\mathbb{C}^2$, and the planes with $v = Ju$ are the complex lines.)
3. $\|\xi\| = 2$: by (2), $\|\xi\| \ge \omega(\xi) = 2$, and by Proposition 12.6.6(3), $\|\xi\| \le |e_{12}| + |e_{34}| = 2$. In particular ξ is not simple, by part (2) of the proposition; directly, $\xi \wedge \xi = 2e_{1234} \ne 0$, while $v \wedge w \wedge v \wedge w = 0$.

So the Euclidean norm underestimates the size of ξ, which consists of two unit squares in orthogonal planes and should have total area 2, and overestimates the size of ω, which measures every unit square by at most 1.

12.7 Forms of type (p, q)

Let V be a real vector space of dimension $2n$ with a complex structure J and $W = V^* = \mathrm{Hom}_{\mathbb{R}}(V, \mathbb{R})$. Then $W_{\mathbb{C}} = W \otimes_{\mathbb{R}} \mathbb{C}$ is identified with $\mathrm{Hom}_{\mathbb{R}}(V, \mathbb{C})$, and $\Lambda^k(W_{\mathbb{C}})$ (exterior power over $\mathbb{C}$) with $\Lambda^k(W) \otimes_{\mathbb{R}} \mathbb{C}$, the complex-valued alternating k-forms on V.

Definition 12.7.1. Let $W^{1,0} \subseteq W_{\mathbb{C}}$ be the space of $\mathbb{R}$-linear maps $\varphi\colon V \to \mathbb{C}$ with $\varphi(Jv) = i\varphi(v)$, that is, the $\mathbb{C}$-linear maps $(V, J) \to \mathbb{C}$, and $W^{0,1} = \overline{W^{1,0}}$, the maps with $\varphi(Jv) = -i\varphi(v)$. For $p, q \geq 0$ let $\Lambda^{p,q} \subseteq \Lambda^{p+q}(W_{\mathbb{C}})$ be the span of the products $\alpha \wedge \beta$ with $\alpha \in \Lambda^p W^{1,0}$ and $\beta \in \Lambda^q W^{0,1}$. Its elements are the forms of *type* (p, q).

Proposition 12.7.2. *1. $W_{\mathbb{C}} = W^{1,0} \oplus W^{0,1}$, and both summands have complex dimension n.*

2. $\Lambda^k(W_{\mathbb{C}}) = \bigoplus_{p+q=k} \Lambda^{p,q}$, with $\dim_{\mathbb{C}} \Lambda^{p,q} = \binom{n}{p}\binom{n}{q}$, and $\overline{\Lambda^{p,q}} = \Lambda^{q,p}$.

3. A real 2-form $\alpha \in \Lambda^2(W)$ lies in $\Lambda^{1,1}$ if and only if $\alpha(Jv, Jw) = \alpha(v, w)$ for all v, w.

Proof. (1) The map $J^*\colon W \to W$, $\varphi \mapsto \varphi \circ J$, is a complex structure on W, and $W^{1,0}$, $W^{0,1}$ are the $\pm i$-eigenspaces of its complexification; apply Proposition 11.11.2. (2) Choose a basis $\zeta_1, \ldots, \zeta_n$ of $W^{1,0}$; then $\bar\zeta_1, \ldots, \bar\zeta_n$ is a basis of $W^{0,1}$ and together they form a basis of $W_{\mathbb{C}}$. By Proposition 12.3.3(3) the products $\zeta_I \wedge \bar\zeta_{I'}$ with $|I| + |I'| = k$ form a basis of $\Lambda^k(W_{\mathbb{C}})$ (after reordering factors, which only changes signs), and those with $|I| = p$, $|I'| = q$ span $\Lambda^{p,q}$. Complex conjugation, extended to forms, maps $\zeta_I \wedge \bar\zeta_{I'}$ to $\bar\zeta_I \wedge \zeta_{I'}$. (3) The map $\alpha \mapsto J^*\alpha$, $(J^*\alpha)(v, w) = \alpha(Jv, Jw)$, equals Λ^2 of J^* on $W_{\mathbb{C}}$. On $\Lambda^{2,0}$ it acts by $i \cdot i = -1$, on $\Lambda^{0,2}$ by $(-i)(-i) = -1$, and on $\Lambda^{1,1}$ by $i(-i) = 1$. So $\Lambda^{1,1}$ is exactly the fixed space of J^* on $\Lambda^2(W_{\mathbb{C}})$. □

Example 12.7.3. On $\mathbb{R}^{2n} = \mathbb{C}^n$ with the standard structure (Example 11.11.4) let dx_j, dy_j be the dual basis and $dz_j = dx_j + i\,dy_j$, $d\bar z_j = dx_j - i\,dy_j$. Then $dz_j \in W^{1,0}$, since $dz_j(J\partial_{x_j}) = dz_j(\partial_{y_j}) = i = i\,dz_j(\partial_{x_j})$ and similarly on ∂_{y_j}. The fundamental form of the standard inner product is

$$\omega = \sum_j dx_j \wedge dy_j = \frac{i}{2} \sum_j dz_j \wedge d\bar z_j,$$

because $dz_j \wedge d\bar z_j = -2i\,dx_j \wedge dy_j$. It is a real form of type $(1, 1)$, in accordance with Proposition 12.7.2(3) and Proposition 11.11.3.

12.8 Exercises

Exercise 12.8.1. Show that $\dim S^d(k^n) = \binom{n+d-1}{d}$.

Exercise 12.8.2. Let $v \in V$ be nonzero and $\alpha \in \Lambda^p(V)$. Show that $v \wedge \alpha = 0$ if and only if $\alpha = v \wedge \beta$ for some $\beta \in \Lambda^{p-1}(V)$.

Exercise 12.8.3. Let $\mathrm{char}\, k \neq 2$. Show that $\omega \in \Lambda^2(V)$ is decomposable, $\omega = v \wedge w$, if and only if $\omega \wedge \omega = 0$.

Exercise 12.8.4. In the situation of Theorem 12.6.3, show that $\alpha \wedge *\alpha = \|\alpha\|^2 \,\mathrm{vol}$, and compute $*$ on $\Lambda^1(\mathbb{R}^2)$: it is the rotation by 90 degrees.

Solution. The first identity is the definition with $\beta = \alpha$. On $\mathbb{R}^2$, $*e_1 = e_2$ and $*e_2 = -e_1$, since $e_1 \wedge e_2 = \mathrm{vol}$ and $e_2 \wedge (-e_1) = \mathrm{vol}$. This is the standard complex structure J. □

Exercise 12.8.5. Let $V = \mathbb{C}^n$. Show that the real (k, k)-forms, that is, $\alpha \in \Lambda^{k,k}$ with $\bar\alpha = \alpha$, form a real vector space of dimension $\binom{n}{k}^2$.

Exercise 12.8.6. With notation as in Section 12.7, let C act on $\Lambda^{p,q}$ as multiplication by i^{p-q}. Show that C commutes with complex conjugation, so preserves real forms, and that C is the map induced on $\Lambda(W_{\mathbb{C}})$ by J^*.

Exercise 12.8.7. Let $X \in M_m(k)$, $\operatorname{char} k = 0$, and $A = \begin{pmatrix} 0 & X \\ -X^T & 0 \end{pmatrix} \in M_{2m}(k)$. Show that $\operatorname{Pf}(A) = (-1)^{m(m-1)/2} \det X$, and check the case $m = 2$ against the formula of Proposition 12.5.9(1). Show also that Pf of a block diagonal matrix with skew-symmetric blocks A_1, A_2 of even sizes is $\operatorname{Pf}(A_1)\operatorname{Pf}(A_2)$.

Solution. Here $\alpha_A = \sum_{i,j} X_{ij}\, e_i^* \wedge e_{m+j}^* = \sum_{i=1}^m e_i^* \wedge \varphi_i$ with $\varphi_i = \sum_j X_{ij} e_{m+j}^*$. The 2-forms $e_i^* \wedge \varphi_i$ commute and square to zero, so $\alpha_A^m = m!\,(e_1^* \wedge \varphi_1) \wedge \cdots \wedge (e_m^* \wedge \varphi_m)$. Moving all the e_i^* to the front, φ_j must pass $e_{j+1}^*, \ldots, e_m^*$, which gives the sign $(-1)^{(m-1)+(m-2)+\cdots+0} = (-1)^{m(m-1)/2}$; and $\varphi_1 \wedge \cdots \wedge \varphi_m = \det(X)\, e_{m+1}^* \wedge \cdots \wedge e_{2m}^*$ by Proposition 12.3.3(5). So $\alpha_A^m = m!\,(-1)^{m(m-1)/2} \det(X)\, e_1^* \wedge \cdots \wedge e_{2m}^*$. For $m = 2$, $A_{12} = A_{34} = 0$, $A_{13} = X_{11}$, $A_{24} = X_{22}$, $A_{14} = X_{12}$, $A_{23} = X_{21}$, and the formula gives $-X_{11}X_{22} + X_{12}X_{21} = -\det X$, in accordance with $(-1)^1 = -1$. For the block diagonal matrix, of sizes $2m_1$ and $2m_2$, $\alpha_A = \alpha_{A_1} + \alpha_{A_2}$ with α_{A_1}, α_{A_2} commuting 2-forms in disjoint sets of variables. In $(\alpha_{A_1} + \alpha_{A_2})^{m_1+m_2}$ only the term $\binom{m_1+m_2}{m_1} \alpha_{A_1}^{m_1} \alpha_{A_2}^{m_2}$ survives, since a power of α_{A_i} above m_i vanishes, and it equals $\frac{(m_1+m_2)!}{m_1!m_2!}\, m_1!\operatorname{Pf}(A_1)\, m_2!\operatorname{Pf}(A_2)\, e_1^* \wedge \cdots \wedge e_{2m}^*$. □

Chapter 13

Representations of Groups and Lie Algebras

13.1 Introduction

A representation of a group or a Lie algebra is an action by linear maps. This chapter develops the basic theory: Schur's lemma, Maschke's theorem, unitary representations and character theory for finite groups, nilpotent and solvable Lie algebras with the theorems of Engel and Lie, and the complete classification of the finite-dimensional representations of the Lie algebra $\mathfrak{sl}_2(\mathbb{C})$. It then develops the structure theory of semisimple Lie algebras: Cartan's criteria and the Killing form, Weyl's theorem on complete reducibility, the root space decomposition, root systems and their classification by Dynkin diagrams, and highest weights (Sections 13.7–13.11). The classification for $\mathfrak{sl}_2$ is used repeatedly in Hodge theory: on the cohomology of a compact Kähler manifold the Lefschetz operator, its adjoint and the degree operator span a copy of $\mathfrak{sl}_2$, and the hard Lefschetz theorem and the primitive decomposition are consequences of the structure of $\mathfrak{sl}_2$-representations (Chapters 47 and 49).

References are [Ser77], [FH91] and [Hum72].

Prerequisites. Chapter 7 (Groups), Chapter 9 (Fields and Galois Theory), Chapter 11 (Linear Algebra) and Chapter 12 (Multilinear Algebra).

On the way to the Hodge conjecture. Only the basic definitions (Section 13.2) and the representations of $\mathfrak{sl}_2$ (Section 13.6), which give the hard Lefschetz theorem, are used on the direct route. Unitary representations (Subsection 13.2.1) return for compact Lie groups, whose representations are unitary by averaging over Haar measure. Characters of finite groups and the structure theory of semisimple Lie algebras are used later only for algebraic groups and Mumford–Tate groups.

Throughout, k is a field and representations are on k-vector spaces.

13.2 Representations of groups

Definition 13.2.1. A *representation* of a group G is a vector space V with a homomorphism $\rho\colon G \to \mathrm{GL}(V)$; we write gv for $\rho(g)v$. A *homomorphism* of representations (or G-equivariant map) is a linear map f with $f(gv) = gf(v)$; the space of such maps is $\mathrm{Hom}_G(V, W)$. A *subrepresentation* is a G-stable subspace. V is *irreducible* if $V \neq 0$ and its only subrepresentations are 0 and V, and *completely reducible* (or *semisimple*) if it is a direct sum of irreducible subrepresentations. The *invariants* are $V^G = \{v : gv = v \text{ for all } g\}$.

Example 13.2.2. Given representations V, W: quotients V/U by subrepresentations, $V \oplus W$, $V \otimes W$ with $g(v \otimes w) = gv \otimes gw$, the dual V^* with $(g\varphi)(v) = \varphi(g^{-1}v)$, and $\mathrm{Hom}_k(V, W)$

with $(gf)(v) = gf(g^{-1}v)$ are representations, and $\mathrm{Hom}_k(V,W)^G = \mathrm{Hom}_G(V,W)$. The *trivial representation* is k with $gv = v$. If G acts on a finite set X, the *permutation representation* is k^X with $ge_x = e_{gx}$; for $X = G$ with the left action this is the *regular representation*.

Lemma 13.2.3 (Schur)**.** *Let V, W be irreducible representations. Every $f \in \mathrm{Hom}_G(V,W)$ is zero or an isomorphism. If k is algebraically closed and V is finite-dimensional, then $\mathrm{Hom}_G(V,V) = k \cdot \mathrm{id}$.*

Proof. $\ker f$ and $\mathrm{im}\, f$ are subrepresentations, so $\ker f \in \{0, V\}$ and $\mathrm{im}\, f \in \{0, W\}$. If k is algebraically closed and $f \in \mathrm{Hom}_G(V,V)$, f has an eigenvalue λ, and $f - \lambda \in \mathrm{Hom}_G(V,V)$ is not an isomorphism, hence zero. □

Theorem 13.2.4 (Maschke)**.** *Let G be finite with $\mathrm{char}\, k \nmid |G|$. Every subrepresentation U of a representation V has a G-stable complement. Hence every finite-dimensional representation is completely reducible.*

Proof. Choose a linear projection $\pi\colon V \to U$ (a linear map with $\pi|_U = \mathrm{id}$), using a complement of U (Proposition 11.2.5), and put $\pi_0 = \frac{1}{|G|}\sum_{g\in G} g\pi g^{-1}$. It is G-equivariant, has image in U, and restricts to the identity on U; so $\ker \pi_0$ is a G-stable complement of U. The second statement follows by induction on the dimension. □

Counterexample 13.2.5. Both hypotheses of Maschke's theorem are needed. The group $\mathbb{Z}$ acts on $\mathbb{C}^2$ by $n \mapsto \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix}$; the line $\mathbb{C}e_1$ is stable, but it has no stable complement, since a stable line would be spanned by an eigenvector and e_1 spans the only eigenline. Similarly $\mathbb{Z}/p\mathbb{Z}$ acts on $\mathbb{F}_p^2$ by the same matrices (with n read modulo p), and the representation is not completely reducible although $\mathbb{Z}/p\mathbb{Z}$ is finite; here p divides the order of the group.

13.2.1 Unitary representations

Many representations met in practice do more than act linearly: they preserve lengths and angles. Permutations of the coordinates of $\mathbb{C}^n$, rotations of the plane, the symmetries of a molecule acting on its wave functions are all of this kind. In quantum mechanics this is a principle: the states of a system are the unit vectors of a complex Hilbert space, and a symmetry of the system acts by operators preserving the inner product, so that transition probabilities $|\langle v, w\rangle|^2$ are unchanged. Representations by such operators are called unitary. For them complete reducibility is automatic, and for finite groups every complex representation is of this kind. In this subsection V is a finite-dimensional complex vector space.

Definition 13.2.6. A representation $\rho\colon G \to \mathrm{GL}(V)$ is *unitary* with respect to a Hermitian inner product $\langle -, -\rangle$ on V (Definition 11.10.1) if

$$\langle gv, gw\rangle = \langle v, w\rangle \qquad \text{for all } g \in G \text{ and } v, w \in V,$$

that is, if every $\rho(g)$ is a unitary operator (Definition 11.10.4), so that ρ takes values in the unitary group $\mathrm{U}(V)$. A representation is *unitarisable* if V has a Hermitian inner product for which it is unitary.

The two descriptions agree: a linear map f satisfies $\langle fv, fw\rangle = \langle v, w\rangle$ for all v, w if and only if $\langle f^\dagger f v, w\rangle = \langle v, w\rangle$ for all v, w, that is, $f^\dagger f = \mathrm{id}$. In an orthonormal basis of V the matrices of a unitary representation lie in $\mathrm{U}(n)$, where $n = \dim V$ (Lemma 11.10.5).

Example 13.2.7.

1. A permutation representation $\mathbb{C}^X$ (Example 13.2.2) is unitary for the inner product in which the e_x are orthonormal, since g permutes this orthonormal basis. In particular the regular representation of a finite group is unitary.

2. A one-dimensional representation is a homomorphism $\chi\colon G \to \mathbb{C}^\times$, and it is unitary for some (equivalently, every) inner product on $\mathbb{C}$ if and only if $|\chi(g)| = 1$ for all g, since $\langle \chi(g)v, \chi(g)v\rangle = |\chi(g)|^2\langle v, v\rangle$. So $\mathbb{R} \to \mathbb{C}^\times$, $t \mapsto e^{iat}$, is unitary, while $t \mapsto e^t$ is not unitarisable. For a finite group every $\chi(g)$ is a root of unity, so every one-dimensional representation is unitary.

3. The group $\mathbb{Z}$ acting on $\mathbb{C}^2$ by $n \mapsto \left(\begin{smallmatrix} 1 & n \\ 0 & 1 \end{smallmatrix}\right)$ (Counterexample 13.2.5) is not unitarisable: by Proposition 13.2.8(1) below a unitarisable representation is completely reducible, and this one is not.

Proposition 13.2.8. *Let V be a unitary representation of a group G.*

1. *The orthogonal complement $U^\perp$ of a subrepresentation U is a subrepresentation. Hence V is the orthogonal direct sum of irreducible subrepresentations.*

2. *For every $g \in G$, $\rho(g)^\dagger = \rho(g^{-1})$, and $\rho(g)$ is diagonalisable in an orthonormal basis, with eigenvalues of absolute value* 1. *Consequently* $\operatorname{tr}\rho(g^{-1}) = \overline{\operatorname{tr}\rho(g)}$.

3. *The map $V \to V^*$, $v \mapsto \langle -, v\rangle$, is a conjugate-linear bijection compatible with the actions of G (with the dual representation of Example 13.2.2 on V^*).*

Proof. (1) If U is stable under $\rho(g)$, then $U^\perp$ is stable under $\rho(g)^\dagger$ (Lemma 11.10.5), and $\rho(g)^\dagger = \rho(g)^{-1} = \rho(g^{-1})$ since $\rho(g)$ is unitary. As g runs through G so does g^{-1}, so $U^\perp$ is a subrepresentation. Now induct on $\dim V$: if V is not irreducible (and $V \neq 0$), choose a subrepresentation $0 \neq U \neq V$; then $V = U \oplus U^\perp$ (Theorem 11.10.3), and U and $U^\perp$ are unitary representations of smaller dimension.

(2) The first statement was shown in (1). A unitary operator is normal, so by the spectral theorem (Theorem 11.10.6) it has an orthonormal basis of eigenvectors; if $\rho(g)v = \lambda v$ with $v \neq 0$, then $\langle v, v\rangle = \langle \rho(g)v, \rho(g)v\rangle = |\lambda|^2\langle v, v\rangle$, so $|\lambda| = 1$. In such a basis $\rho(g^{-1})$ is diagonal with entries $\lambda_i^{-1} = \bar{\lambda}_i$, so its trace is $\overline{\operatorname{tr}\rho(g)}$.

(3) The map is conjugate-linear because the inner product is conjugate-linear in the second variable, and it is bijective because a nondegenerate form identifies V with V^* in this way (compute in an orthonormal basis (u_i), where $u_i \mapsto u_i^*$). For compatibility with G, write $\varphi_v = \langle -, v\rangle$; then $(g\varphi_v)(w) = \varphi_v(g^{-1}w) = \langle g^{-1}w, v\rangle = \langle w, gv\rangle = \varphi_{gv}(w)$, using that g preserves the inner product. □

Theorem 13.2.9 (Unitary trick for finite groups)**.** *Every finite-dimensional complex representation V of a finite group G is unitarisable: if $\langle -, -\rangle$ is any Hermitian inner product on V, then*

$$\langle v, w\rangle_G = \frac{1}{|G|}\sum_{g\in G}\langle gv, gw\rangle$$

is a Hermitian inner product for which V is unitary. Consequently every finite subgroup of $\mathrm{GL}_n(\mathbb{C})$ *is conjugate to a subgroup of* $\mathrm{U}(n)$.

Proof. Each summand is linear in v and satisfies $\langle gw, gv\rangle = \overline{\langle gv, gw\rangle}$, so $\langle -, -\rangle_G$ is Hermitian. For $v \neq 0$ every summand $\langle gv, gv\rangle$ is positive, since $gv \neq 0$; so $\langle v, v\rangle_G > 0$. For $h \in G$,

$$\langle hv, hw\rangle_G = \frac{1}{|G|}\sum_{g\in G}\langle ghv, ghw\rangle = \frac{1}{|G|}\sum_{g'\in G}\langle g'v, g'w\rangle = \langle v, w\rangle_G,$$

because $g \mapsto gh$ is a bijection of G. For the last statement, let $G \subseteq \mathrm{GL}_n(\mathbb{C})$ be finite, acting on $\mathbb{C}^n$. Choose an orthonormal basis of $\mathbb{C}^n$ for $\langle -, -\rangle_G$ by the Gram–Schmidt process (Theorem 11.10.3), and let P be the matrix whose columns are its vectors. In this basis the elements of G act by unitary matrices, that is, $P^{-1}GP \subseteq \mathrm{U}(n)$. □

Together with Proposition 13.2.8(1) this gives a second proof of Maschke's theorem over $\mathbb{C}$, with a canonical choice of complement: the orthogonal one. The averaging only uses that one can take the mean of a function over G in a translation invariant way. It therefore works for compact groups, where the sum is replaced by the integral against Haar measure (Chapter 34), and fails for $\mathbb{Z}$, as Example 13.2.7(3) shows. The same argument with real inner products shows that every finite subgroup of $\mathrm{GL}_n(\mathbb{R})$ is conjugate to a subgroup of $\mathrm{O}(n)$: the finite groups of real matrices are, up to a change of basis, groups of symmetries of Euclidean space.

For an irreducible representation the invariant inner product is essentially unique.

Proposition 13.2.10. *Let V be an irreducible finite-dimensional complex representation of a group G, unitary for two Hermitian inner products $\langle -,-\rangle_1$ and $\langle -,-\rangle_2$. Then $\langle -,-\rangle_2 = c\,\langle -,-\rangle_1$ for a real number $c > 0$.*

Proof. Let (u_i) be an orthonormal basis for $\langle -,-\rangle_1$ and define a linear map A by $Av = \sum_i \langle v, u_i\rangle_2\, u_i$. Writing $w = \sum_j \langle w, u_j\rangle_1 u_j$,

$$\langle v, w\rangle_2 = \sum_j \overline{\langle w, u_j\rangle_1}\,\langle v, u_j\rangle_2 = \sum_j \langle v, u_j\rangle_2\,\langle u_j, w\rangle_1 = \langle Av, w\rangle_1$$

for all v, w. The map A is G-equivariant: for $g \in G$, $\langle Agv, w\rangle_1 = \langle gv, w\rangle_2 = \langle v, g^{-1}w\rangle_2 = \langle Av, g^{-1}w\rangle_1 = \langle gAv, w\rangle_1$ for all w, so $Agv = gAv$. By Schur's lemma (Lemma 13.2.3) $A = c\,\mathrm{id}$ for some $c \in \mathbb{C}$, and $c = \langle v, v\rangle_2/\langle v, v\rangle_1 > 0$ for any $v \neq 0$. □

Irreducibility is needed: on the trivial representation $\mathbb{C}^2$ every inner product is invariant.

Remark 13.2.11. In analysis and physics the important unitary representations are infinite-dimensional. A *unitary representation* of a topological group G on a Hilbert space H is a homomorphism from G to the group of unitary operators of H such that $g \mapsto gv$ is continuous for every $v \in H$ (Chapter 30). Examples are the translations $(T_a f)(x) = f(x-a)$ of $\mathbb{R}$ on $L^2(\mathbb{R})$, and the rotations of the circle on $L^2(S^1)$. The latter decomposes as the orthogonal Hilbert sum of the one-dimensional representations spanned by the functions $e^{in\theta}$, $n \in \mathbb{Z}$: this is the theory of Fourier series. For a compact group G the Peter–Weyl theorem gives the analogous decomposition of $L^2(G)$, in which every irreducible representation V occurs $\dim V$ times [BtD85, Chapter III]. For $G = \mathbb{R}$, Stone's theorem says that every unitary representation is of the form $t \mapsto e^{itA}$ for a self-adjoint, in general unbounded, operator A [RS80, Theorem VIII.8]; in quantum mechanics, the time evolution of a system is such a representation and A is its energy, the Hamiltonian.

Exercise 13.2.12. Let S_3 act on $\mathbb{C}^3$ by permuting the coordinates, with the standard inner product. Show that the line spanned by $(1,1,1)$ and its orthogonal complement $W = \{x + y + z = 0\}$ are subrepresentations, and that W is irreducible.

Solution. Permutations fix $(1,1,1)$, so its span is a subrepresentation, and the representation is unitary (Example 13.2.7(1)), so W is a subrepresentation by Proposition 13.2.8(1). If W were reducible, it would contain a stable line spanned by some $v = (a,b,c) \neq 0$ with $a+b+c = 0$, and each transposition, having order 2, would act on it by ± 1. If $(1\,2)v = v$ then $a = b$ and $v = (a,a,-2a)$, and $(2\,3)v = (a,-2a,a) = \pm v$ forces $a = 0$. If $(1\,2)v = -v$ then $b = -a$ and $c = 0$, so $v = (a,-a,0)$, and $(2\,3)v = (a,0,-a) = \pm v$ again forces $a = 0$. Both cases contradict $v \neq 0$. □

13.3 Characters of finite groups

In this section G is finite, $k = \mathbb{C}$, and representations are finite-dimensional.

Definition 13.3.1. The *character* of a representation V is $\chi_V \colon G \to \mathbb{C}$, $\chi_V(g) = \operatorname{tr}(g|_V)$. A *class function* is a function $G \to \mathbb{C}$ constant on conjugacy classes. On class functions put the Hermitian inner product $\langle \phi, \psi \rangle = \frac{1}{|G|} \sum_{g \in G} \phi(g)\overline{\psi(g)}$.

Proposition 13.3.2. *Characters are class functions,* $\chi_V(e) = \dim V$, $\chi_{V \oplus W} = \chi_V + \chi_W$, $\chi_{V \otimes W} = \chi_V \chi_W$, *and* $\chi_{V^*}(g) = \overline{\chi_V(g)} = \chi_V(g^{-1})$. *Moreover* $\dim V^G = \frac{1}{|G|} \sum_g \chi_V(g)$.

Proof. The trace is invariant under conjugation, additive on direct sums and multiplicative on tensor products (compute in bases). Each g has finite order, so $g|_V$ satisfies $x^n - 1$ and is diagonalisable with roots of unity λ_i as eigenvalues (Theorem 11.7.6); then $\chi_{V^*}(g) = \sum \lambda_i^{-1} = \sum \bar{\lambda}_i$. Finally $p = \frac{1}{|G|} \sum_g g$ is a projection onto V^G (it is the identity on V^G and $hp = p$ for all h), and the trace of a projection is the dimension of its image. □

Theorem 13.3.3 (Orthogonality)**.** *For representations* V, W, $\langle \chi_W, \chi_V \rangle = \dim \operatorname{Hom}_G(V, W)$. *Consequently the characters of irreducible representations are orthonormal, a representation is determined up to isomorphism by its character, and* V *is irreducible if and only if* $\langle \chi_V, \chi_V \rangle = 1$.

Proof. $\operatorname{Hom}_G(V, W) = \operatorname{Hom}_{\mathbb{C}}(V, W)^G$, and $\operatorname{Hom}_{\mathbb{C}}(V, W) \cong V^* \otimes W$ as representations, so by Proposition 13.3.2 its dimension is $\frac{1}{|G|} \sum_g \overline{\chi_V(g)} \chi_W(g)$. For irreducible V, W, Schur's lemma gives $\dim \operatorname{Hom}_G(V, W) = 1$ if $V \cong W$ and 0 otherwise. By Maschke's theorem $V \cong \bigoplus_i V_i^{m_i}$ with distinct irreducible V_i, and $m_i = \langle \chi_V, \chi_{V_i} \rangle$ is determined by χ_V; also $\langle \chi_V, \chi_V \rangle = \sum m_i^2$. □

Theorem 13.3.4. *The characters of the irreducible representations of* G *form an orthonormal basis of the space of class functions. In particular the number of isomorphism classes of irreducible representations equals the number of conjugacy classes, and if* $V_1, \dots, V_r$ *are the irreducible representations, then* $\sum_i (\dim V_i)^2 = |G|$.

Proof. The regular representation has character $|G|$ at e and 0 elsewhere, so by Theorem 13.3.3 it contains each V_i with multiplicity $\langle \chi_{\mathrm{reg}}, \chi_{V_i} \rangle = \dim V_i$; comparing dimensions gives $\sum (\dim V_i)^2 = |G|$. In particular there are finitely many irreducible representations up to isomorphism.

It remains to show that a class function ϕ orthogonal to all χ_{V_i} is zero. For a representation V let $T_V = \sum_g \overline{\phi(g)}\, g|_V$. Since ϕ is a class function, T_V commutes with all $h|_V$. If V is irreducible, $T_V = \lambda \mathrm{id}$ by Schur's lemma, and taking traces, $\lambda \dim V = \sum_g \overline{\phi(g)} \chi_V(g) = |G| \langle \chi_V, \phi \rangle = 0$. So $T_V = 0$ for every irreducible V, hence for every V by Maschke's theorem, in particular for the regular representation; but there $T(e_e) = \sum_g \overline{\phi(g)} e_g$, so $\phi = 0$. □

Example 13.3.5. S_3 has three conjugacy classes: $\{e\}$, the three transpositions and the two 3-cycles. Its irreducible representations are the trivial representation, the sign representation and the two-dimensional representation $U = \{x \in \mathbb{C}^3 : x_1 + x_2 + x_3 = 0\}$ (a subrepresentation of the permutation representation). Their characters take the values $(1, 1, 1)$, $(1, -1, 1)$ and $(2, 0, -1)$ on the three classes. One checks orthonormality directly: for instance $\langle \chi_U, \chi_U \rangle = \frac{1}{6}(4 + 0 + 2 \cdot 1) = 1$.

Proposition 13.3.6. *Let* G *be a finite abelian group. Every irreducible complex representation of* G *is one-dimensional, given by a homomorphism* $\chi \colon G \to \mathbb{C}^\times$, *and there are exactly* $|G|$ *of them. For* $G = \mathbb{Z}/n\mathbb{Z}$ *they are* $\chi_j(k) = e^{2\pi i j k/n}$, $0 \le j < n$.

Proof. Let V be irreducible. Each g commutes with the action of G, so by Schur's lemma (Lemma 13.2.3) it acts by a scalar; then every line in V is a subrepresentation, and $\dim V = 1$. The conjugacy classes of an abelian group are its elements, so by Theorem 13.3.4 there are $|G|$ irreducible representations. For $\mathbb{Z}/n\mathbb{Z}$, a homomorphism to $\mathbb{C}^\times$ is determined by the image ζ of 1, with $\zeta^n = 1$, and the n choices give the χ_j. □

Corollary 13.3.7. *The one-dimensional complex representations of a group G are the homomorphisms $G \to \mathbb{C}^\times$, and they all factor through the abelianisation $G^{\mathrm{ab}} = G/[G,G]$ (Proposition 7.9.2). For finite G there are exactly $[G : [G,G]]$ of them.*

Proof. A one-dimensional representation is a homomorphism $G \to \mathrm{GL}_1(\mathbb{C}) = \mathbb{C}^\times$, and $\mathbb{C}^\times$ is abelian. So they correspond to the homomorphisms $G^{\mathrm{ab}} \to \mathbb{C}^\times$, which by Proposition 13.3.6, applied to the finite abelian group G^{ab}, are $|G^{\mathrm{ab}}|$ in number. □

For example $[S_n, S_n] = A_n$ for $n \geq 2$ (Exercise 7.12.3), so S_n has exactly two one-dimensional representations, the trivial one and the sign; a perfect group, such as A_5, has only the trivial one. The analogue for Lie algebras: one-dimensional representations of $\mathfrak{g}$ are the linear forms vanishing on $[\mathfrak{g},\mathfrak{g}]$, so a Lie algebra with $[\mathfrak{g},\mathfrak{g}] = \mathfrak{g}$, for instance a semisimple one, has only the trivial one.

Counterexample 13.3.8. The second statement of Schur's lemma needs an algebraically closed field. The group $\mathbb{Z}/4\mathbb{Z}$ acting on $\mathbb{R}^2$ by rotation by $\pi/2$, with generator acting by $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, is irreducible over $\mathbb{R}$, since J has no real eigenvector; but its endomorphisms, the matrices commuting with J, are the $aI + bJ$, a field isomorphic to $\mathbb{C}$, not $\mathbb{R} \cdot \mathrm{id}$. Over $\mathbb{C}$ the representation splits as $\chi_1 \oplus \chi_3$ in the notation of Proposition 13.3.6.

Definition 13.3.9. Let $H \subseteq G$ be a subgroup of a finite group and W a representation of H. The *induced representation* is $\mathrm{Ind}_H^G W = \{f : G \to W : f(hx) = hf(x) \text{ for } h \in H, x \in G\}$, with $(gf)(x) = f(xg)$. For a representation V of G, $\mathrm{Res}_H^G V$ is V viewed as a representation of H.

Proposition 13.3.10 (Frobenius reciprocity)**.** *In the situation of Definition 13.3.9:*

1. $\mathrm{Hom}_G(V, \mathrm{Ind}_H^G W) \cong \mathrm{Hom}_H(\mathrm{Res}_H^G V, W)$, *via* $\varphi \mapsto (v \mapsto \varphi(v)(e))$;
2. $\dim \mathrm{Ind}_H^G W = [G : H] \dim W$, *and*
$$\chi_{\mathrm{Ind}\, W}(g) = \frac{1}{|H|} \sum_{x \in G,\ xgx^{-1} \in H} \chi_W(xgx^{-1});$$
3. $\langle \chi_{\mathrm{Ind}\, W}, \chi_V \rangle_G = \langle \chi_W, \chi_{\mathrm{Res}\, V} \rangle_H$.

Proof. (1) If φ is G-equivariant, then $\psi(v) = \varphi(v)(e)$ satisfies $\psi(hv) = \varphi(hv)(e) = (h\varphi(v))(e) = \varphi(v)(h) = h\varphi(v)(e) = h\psi(v)$. Conversely, for $\psi \in \mathrm{Hom}_H(V, W)$ put $\varphi(v)(x) = \psi(xv)$; then $\varphi(v)(hx) = \psi(hxv) = h\varphi(v)(x)$, so $\varphi(v) \in \mathrm{Ind}\, W$, and $\varphi(gv)(x) = \psi(xgv) = \varphi(v)(xg) = (g\varphi(v))(x)$. The two constructions are inverse, since $\varphi(v)(x) = (x\varphi(v))(e) = \varphi(xv)(e)$.

(2) Choose representatives $x_1, \dots, x_m$ of the cosets Hx, $m = [G : H]$. An element f is determined by the values $f(x_i)$, which are arbitrary, so $f \mapsto (f(x_i))_i$ is an isomorphism with W^m. For $g \in G$ write $x_i g = h_i x_{\sigma(i)}$ with $h_i \in H$ and σ a permutation; then $(gf)(x_i) = f(x_i g) = h_i f(x_{\sigma(i)})$. So in the decomposition W^m, g maps the $\sigma(i)$-th summand to the i-th by h_i, and only the indices with $\sigma(i) = i$ contribute to the trace, with $h_i = x_i g x_i^{-1} \in H$. Hence $\chi_{\mathrm{Ind}\, W}(g) = \sum_{i : x_i g x_i^{-1} \in H} \chi_W(x_i g x_i^{-1})$, and since χ_W is a class function on H, each coset Hx_i contributes $|H|$ equal terms to the sum in the statement.

(3) By Theorem 13.3.3, both sides are dimensions of the spaces in (1): the left side is $\dim \mathrm{Hom}_G(V, \mathrm{Ind}_H^G W)$ and the right side is $\dim \mathrm{Hom}_H(\mathrm{Res}_H^G V, W)$. □

Counterexample 13.3.11. The character table does not determine the group. Let G be a group of order 8 whose centre Z has order 2 and with $G/Z \cong (\mathbb{Z}/2\mathbb{Z})^2$; the dihedral group D_4 of symmetries of a square and the quaternion group $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ are examples. For $x \notin Z$ the centraliser contains $\langle x\rangle Z$, of order 4, and is not G, so the class of x is $\{x, zx\}$, $Z = \{e, z\}$: there are five classes. For $x \notin Z$, $x^2 \in Z$ and every conjugate of x lies in xZ, because G/Z is abelian of exponent 2. The commutator subgroup is Z (G/Z is abelian and G is not), so the one-dimensional characters are the four characters of G/Z, equal to 1 at z; at each non-identity element of G/Z two of them take the value 1 and two the value -1; by Theorem 13.3.4 the fifth irreducible character χ has degree 2 ($4 + 2^2 = 8$), and comparing with the regular character, $2\chi = \chi_{\text{reg}} - \sum \chi_{\text{1-dim}}$ gives $\chi(z) = -2$ and $\chi(x) = 0$ for $x \notin Z$. So the character tables of D_4 and Q_8 coincide, but the groups are not isomorphic: D_4 has five elements of order 2 and Q_8 only one.

13.3.1 Computing character tables

The *character table* of G lists the values of the irreducible characters $\chi_1, \dots, \chi_r$ on representatives $g_1, \dots, g_r$ of the conjugacy classes; by Theorem 13.3.4 it is a square matrix. It is usually found without constructing all the representations, by combining a few known characters with the orthogonality relations. Besides the orthogonality of rows (Theorem 13.3.3) there is an orthogonality of columns. We write $C_G(g) = \{x : xg = gx\}$ for the centraliser; the class of g has $|G|/|C_G(g)|$ elements.

Proposition 13.3.12 (Column orthogonality)**.** *For $g, h \in G$,*

$$\sum_{i=1}^{r} \chi_i(g)\overline{\chi_i(h)} = \begin{cases} |C_G(g)| & \text{if } g \text{ and } h \text{ are conjugate,} \\ 0 & \text{otherwise.} \end{cases}$$

In particular $\sum_i \chi_i(e)^2 = |G|$ and $\sum_i \chi_i(e)\chi_i(g) = 0$ for $g \neq e$.

Proof. Let $c_j = |G|/|C_G(g_j)|$ be the size of the j-th class, and let M be the $r \times r$ matrix with entries $M_{ij} = \chi_i(g_j)\sqrt{c_j/|G|}$. Since characters are class functions, row orthogonality says $\sum_j M_{ij}\overline{M_{kj}} = \frac{1}{|G|}\sum_j c_j \chi_i(g_j)\overline{\chi_k(g_j)} = \langle \chi_i, \chi_k\rangle = \delta_{ik}$, so M is a unitary matrix. Then also $M^*M = I$, that is, $\sum_i \overline{M_{ij}}M_{il} = \delta_{jl}$, which is the formula for $g = g_l$ and $h = g_j$ after dividing by $\sqrt{c_j c_l}/|G|$. For $g = e$ the values $\chi_i(e)$ are the dimensions, which are real. □

Here are the other tools.

1. *Lifting from quotients.* If N is a normal subgroup, every irreducible representation of G/N composed with $G \to G/N$ is an irreducible representation of G (the images of G and of G/N in $\mathrm{GL}(V)$ are the same), with character constant on cosets of N. The one-dimensional characters are the lifts from G^{ab} (Corollary 13.3.7).

2. *Twisting.* If χ is irreducible and λ is one-dimensional, then $\lambda\chi$ is the character of an irreducible representation, since $|\lambda(g)| = 1$ gives $\langle \lambda\chi, \lambda\chi\rangle = \langle \chi, \chi\rangle = 1$.

3. *Permutation characters*, by the next proposition.

4. *Real values.* If g is conjugate to g^{-1}, then $\chi(g) = \chi(g^{-1}) = \overline{\chi(g)}$ is real for every character (Proposition 13.3.2).

Proposition 13.3.13. *Let G act on a finite set X and let $\pi(g) = |\{x \in X : gx = x\}|$ be the character of the permutation representation $\mathbb{C}[X]$ (which has basis X, permuted by G). Then $\langle \pi, 1\rangle$ is the*

number of orbits of G on X, and $\langle \pi, \pi \rangle$ is the number of orbits of G on $X \times X$. If the action is doubly transitive, *that is, $|X| \geq 2$ and G acts transitively on the pairs (x, y) with $x \neq y$, then $\pi = 1 + \chi$ with χ irreducible.*

Proof. The matrix of g in the basis X is a permutation matrix, whose trace is the number of fixed points. By Proposition 13.3.2, $\langle \pi, 1 \rangle = \dim \mathbb{C}[X]^G$, and an element $\sum_x a_x x$ is invariant exactly when $x \mapsto a_x$ is constant on orbits; so the invariants have a basis indexed by the orbits. Since π is real, $\langle \pi, \pi \rangle = \langle \pi^2, 1 \rangle$, and $\pi(g)^2$ is the number of fixed points of g on $X \times X$; so it is the number of orbits on $X \times X$. For a doubly transitive action there are two orbits on $X \times X$, the diagonal and its complement, and one on X. Then $\chi = \pi - 1$ satisfies $\langle \chi, \chi \rangle = \langle \pi, \pi \rangle - 2\langle \pi, 1 \rangle + 1 = 2 - 2 + 1 = 1$, and $\chi(e) = |X| - 1 > 0$, so χ is an irreducible character by Theorem 13.3.3. □

For S_n acting on $\{1, \ldots, n\}$, which is doubly transitive for $n \geq 2$, this gives the *standard representation* of dimension $n - 1$, with character (number of fixed points) $- 1$; for $n = 3$ it is the representation U of Example 13.3.5. The alternating group A_n is doubly transitive on $\{1, \ldots, n\}$ for $n \geq 4$ (given $x \neq y$ and $x' \neq y'$, a permutation taking x, y to x', y' can be composed with a transposition of two other points to make it even).

Example 13.3.14 (The alternating group A_4)**.** A_4 has order 12. Its classes are: $\{e\}$; the three double transpositions such as (12)(34); and the eight 3-cycles, which split into two classes of four. Indeed, the centraliser of (123) in S_4 is the group $\langle (123) \rangle$ of order 3 (an element commuting with (123) preserves its set of fixed points $\{4\}$ and permutes $\{1, 2, 3\}$ by a power of the cycle), so its class in A_4 has $12/3 = 4$ elements; the classes of (123) and $(132) = (123)^{-1}$ are different, as we shall see. The Klein group $V = \{e, (12)(34), (13)(24), (14)(23)\}$ is normal, and A_4/V has order 3, so it is cyclic, generated by the image of (123). With $\omega = e^{2\pi i/3}$, the three characters of $A_4/V \cong \mathbb{Z}/3\mathbb{Z}$ lift to one-dimensional characters $1, \lambda, \lambda^2$ with $\lambda((123)) = \omega$ and $\lambda((132)) = \omega^2$. Since $\omega \neq \omega^2$, the elements (123) and (132) are not conjugate, so there are four classes and four irreducible characters, with $\sum \chi_i(e)^2 = 12$; the fourth has degree 3. It is the restriction of the standard representation of S_4, irreducible because A_4 is doubly transitive on four points: fixed points minus one gives $(3, -1, 0, 0)$. The table is

	e	(12)(34)	(123)	(132)
class size	1	3	4	4
1	1	1	1	1
λ	1	1	ω	ω^2
λ^2	1	1	ω^2	ω
χ_3	3	-1	0	0

As a check, the column of (12)(34) has $\sum_i |\chi_i|^2 = 1 + 1 + 1 + 1 = 4 = |C_{A_4}((12)(34))|$ (its centraliser is V), and the column of (123) has $1 + 1 + 1 + 0 = 3$. The representation χ_3 is the action of A_4 as the rotation group of a regular tetrahedron: a rotation by π about an axis through midpoints of opposite edges has trace $1 + 2\cos\pi = -1$, a rotation by $2\pi/3$ about an axis through a vertex has trace $1 + 2\cos(2\pi/3) = 0$.

Example 13.3.15 (The alternating group A_5 and the golden ratio)**.** A_5 has order 60 and five classes: $\{e\}$; the 15 double transpositions; the 20 three-cycles; and the 24 five-cycles, which split into two classes of 12, represented by $x = (12345)$ and $x^2 = (13524)$. (The centraliser of x in S_5 is $\langle x \rangle$, of order 5 and contained in A_5, so the class of x in A_5 has 12 elements. A permutation σ with $\sigma x \sigma^{-1} = x^2$ is $\sigma = (2354)$, and all others differ from it by elements of $\langle x \rangle$; they are all odd, so x and x^2 are not conjugate in A_5. On the other hand $x^{-1} = (15432) = \tau x \tau^{-1}$ with $\tau = (25)(34)$ even, so x is conjugate to x^{-1} in A_5, and all characters are real.) The centralisers have orders $60, 4, 3, 5, 5$.

A_5 is perfect, so the only one-dimensional character is the trivial one. Doubly transitive action on $\{1,\dots,5\}$ gives $\chi_4 = (\text{fixed points}) - 1 = (4,0,1,-1,-1)$. The action on the ten two-element subsets of $\{1,\dots,5\}$ has permutation character $\pi = (10,2,1,0,0)$ (the double transposition (12)(34) fixes $\{1,2\}$ and $\{3,4\}$, the 3-cycle (123) fixes $\{4,5\}$). Then $\langle\pi,\pi\rangle = \frac{1}{60}(100 + 15\cdot 4 + 20\cdot 1) = 3$, $\langle\pi,1\rangle = 1$ and $\langle\pi,\chi_4\rangle = \frac{1}{60}(40+20) = 1$, so $\chi_5 = \pi - 1 - \chi_4 = (5,1,-1,0,0)$ has $\langle\chi_5,\chi_5\rangle = 3-1-1 = 1$ and is irreducible. The remaining two irreducible characters have $\chi(e)^2 + \chi'(e)^2 = 60-1-16-25 = 18$, so both have degree 3; write their values as $(3,a,b,c,d)$ and $(3,a',b',c',d')$, real numbers.

Column orthogonality with the column of e gives $1+0+5+3(a+a') = 0$, $1+4-5+3(b+b') = 0$ and $1-4+0+3(c+c') = 0$, that is, $a+a' = -2$, $b+b' = 0$, $c+c' = 1$, and likewise $d+d' = 1$. The norms of the columns give $1+0+1+a^2+a'^2 = 4$, $1+1+1+b^2+b'^2 = 3$ and $1+1+0+c^2+c'^2 = 5$. Hence $a^2+a'^2 = 2$ with $a+a' = -2$, forcing $a = a' = -1$; $b = b' = 0$; and $c+c' = 1$, $c^2+c'^2 = 3$, so $cc' = -1$ and c, c' are the roots of $t^2 - t - 1$, namely

$$\varphi = \frac{1+\sqrt{5}}{2} \quad \text{and} \quad 1-\varphi = \frac{1-\sqrt{5}}{2}.$$

The same holds for d, d', and orthogonality of the columns of x and x^2 gives $1+1+0+cd+c'd' = 0$, which excludes $d = c$ (then $cd + c'd' = 3$); so $d = c'$ and $d' = c$. The table is

	e	(12)(34)	(123)	(12345)	(13524)
class size	1	15	20	12	12
1	1	1	1	1	1
χ_3	3	−1	0	φ	$1-\varphi$
χ_3'	3	−1	0	$1-\varphi$	φ
χ_4	4	0	1	−1	−1
χ_5	5	1	−1	0	0

The golden ratio has a geometric meaning: A_5 is the rotation group of the regular icosahedron, and χ_3 is this three-dimensional representation. The element x acts as a rotation by $2\pi/5$ about an axis through two opposite vertices, with trace $1 + 2\cos(2\pi/5) = 1 + \frac{\sqrt{5}-1}{2} = \varphi$. The representation χ_3' is obtained from χ_3 by the field automorphism $\sqrt{5} \mapsto -\sqrt{5}$, or equivalently by composing with conjugation by an odd permutation, which exchanges the two classes of 5-cycles.

13.4 Lie algebras

Definition 13.4.1. A *Lie algebra* over k is a vector space $\mathfrak{g}$ with a bilinear map $[-,-]\colon \mathfrak{g}\times\mathfrak{g} \to \mathfrak{g}$, the *bracket*, with $[x,x] = 0$ and the *Jacobi identity* $[x,[y,z]] + [y,[z,x]] + [z,[x,y]] = 0$. A *homomorphism* of Lie algebras is a linear map preserving brackets, an *ideal* is a subspace $\mathfrak{a}$ with $[\mathfrak{g},\mathfrak{a}] \subseteq \mathfrak{a}$, and $\mathfrak{g}$ is *abelian* if its bracket is zero.

Example 13.4.2.

1. For an associative algebra A, the commutator $[x,y] = xy - yx$ makes A a Lie algebra. For $A = \operatorname{End}(V)$ this is $\mathfrak{gl}(V)$, and for $A = M_n(k)$ it is $\mathfrak{gl}_n(k)$.
2. $\mathfrak{sl}_n(k) = \{x \in \mathfrak{gl}_n(k) : \operatorname{tr} x = 0\}$ is a Lie subalgebra, since $\operatorname{tr}[x,y] = 0$ (Exercise 11.12.1).
3. The skew-symmetric matrices form $\mathfrak{so}_n(k)$, and more generally the x with $B(xv,w) + B(v,xw) = 0$ for a bilinear form B form a Lie subalgebra of $\mathfrak{gl}(V)$.

Definition 13.4.3. A *representation* of a Lie algebra $\mathfrak{g}$ is a vector space V with a Lie algebra homomorphism $\mathfrak{g} \to \mathfrak{gl}(V)$; we write xv for the action, so $[x,y]v = x(yv) - y(xv)$. Subrepresentations, irreducibility, homomorphisms and direct sums are defined as for groups. The

tensor product $V \otimes W$ is a representation with $x(v \otimes w) = xv \otimes w + v \otimes xw$, and the dual with $(x\varphi)(v) = -\varphi(xv)$. The *adjoint representation* is $\mathfrak{g}$ itself with $x \cdot y = [x, y]$, a representation by the Jacobi identity.

Remark 13.4.4. Lie algebras arise as tangent spaces of Lie groups at the identity (Chapter 34), and representations of a Lie group differentiate to representations of its Lie algebra; the formula for the tensor product is the derivative of $g(v \otimes w) = gv \otimes gw$.

13.5 Nilpotent and solvable Lie algebras

The Lie algebras of upper triangular and of strictly upper triangular matrices are the models of two classes of Lie algebras, the solvable and the nilpotent ones. The theorems of Engel and Lie say that, conversely, a Lie algebra of nilpotent matrices can be put in strictly upper triangular form, and a solvable Lie algebra of matrices over $\mathbb{C}$ in upper triangular form, by one change of basis for all its elements at once. In this section all Lie algebras and representations are finite-dimensional. For subspaces $\mathfrak{a}, \mathfrak{b} \subseteq \mathfrak{g}$, $[\mathfrak{a}, \mathfrak{b}]$ is the subspace spanned by the brackets $[x, y]$ with $x \in \mathfrak{a}$, $y \in \mathfrak{b}$, and the *centre* of $\mathfrak{g}$ is $\mathfrak{z}(\mathfrak{g}) = \{x : [x, y] = 0 \text{ for all } y\}$. We write $\operatorname{ad} x \colon \mathfrak{g} \to \mathfrak{g}$ for $y \mapsto [x, y]$, the adjoint representation of Definition 13.4.3.

Definition 13.5.1. The *derived series* of a Lie algebra $\mathfrak{g}$ is $D^0\mathfrak{g} = \mathfrak{g}$, $D^{i+1}\mathfrak{g} = [D^i\mathfrak{g}, D^i\mathfrak{g}]$, and its *lower central series* is $C^1\mathfrak{g} = \mathfrak{g}$, $C^{i+1}\mathfrak{g} = [\mathfrak{g}, C^i\mathfrak{g}]$. The Lie algebra $\mathfrak{g}$ is *solvable* if $D^m\mathfrak{g} = 0$ for some m, and *nilpotent* if $C^m\mathfrak{g} = 0$ for some m.

So $\mathfrak{g}$ is nilpotent when all iterated brackets $[x_1, [x_2, [\cdots, [x_{m-1}, x_m]\cdots]]]$ of a fixed length m vanish; abelian Lie algebras are nilpotent with $m = 2$.

Lemma 13.5.2. *1. If $\mathfrak{a}$ and $\mathfrak{b}$ are ideals, so is $[\mathfrak{a}, \mathfrak{b}]$. Hence all $D^i\mathfrak{g}$ and $C^i\mathfrak{g}$ are ideals, and $D^i\mathfrak{g} \subseteq C^{i+1}\mathfrak{g}$; in particular nilpotent Lie algebras are solvable.*

2. Subalgebras and homomorphic images of solvable (nilpotent) Lie algebras are solvable (nilpotent).

3. If $\mathfrak{a}$ is a solvable ideal of $\mathfrak{g}$ and $\mathfrak{g}/\mathfrak{a}$ is solvable, then $\mathfrak{g}$ is solvable.

4. A nonzero nilpotent Lie algebra has nonzero centre; and if $\mathfrak{g}/\mathfrak{z}(\mathfrak{g})$ is nilpotent, so is $\mathfrak{g}$.

Proof. (1) For $x \in \mathfrak{g}$, $a \in \mathfrak{a}$, $b \in \mathfrak{b}$ the Jacobi identity gives $[x, [a, b]] = [[x, a], b] + [a, [x, b]] \in [\mathfrak{a}, \mathfrak{b}]$. By induction the terms of both series are ideals. Also $D^0\mathfrak{g} = C^1\mathfrak{g}$, and if $D^i\mathfrak{g} \subseteq C^{i+1}\mathfrak{g}$ then $D^{i+1}\mathfrak{g} = [D^i\mathfrak{g}, D^i\mathfrak{g}] \subseteq [\mathfrak{g}, C^{i+1}\mathfrak{g}] = C^{i+2}\mathfrak{g}$.

(2) For a subalgebra $\mathfrak{h}$, induction gives $D^i\mathfrak{h} \subseteq D^i\mathfrak{g}$ and $C^i\mathfrak{h} \subseteq C^i\mathfrak{g}$. For a surjective homomorphism $\varphi \colon \mathfrak{g} \to \mathfrak{g}'$, $\varphi([\mathfrak{a}, \mathfrak{b}]) = [\varphi(\mathfrak{a}), \varphi(\mathfrak{b})]$, so $\varphi(D^i\mathfrak{g}) = D^i\mathfrak{g}'$ and $\varphi(C^i\mathfrak{g}) = C^i\mathfrak{g}'$.

(3) If $D^m(\mathfrak{g}/\mathfrak{a}) = 0$, then $D^m\mathfrak{g} \subseteq \mathfrak{a}$ by (2) applied to the projection, and by induction $D^{m+l}\mathfrak{g} \subseteq D^l\mathfrak{a}$, which vanishes for large l.

(4) Let m be least with $C^m\mathfrak{g} = 0$; as $\mathfrak{g} \neq 0$, $m \geq 2$ and $C^{m-1}\mathfrak{g} \neq 0$. Since $[\mathfrak{g}, C^{m-1}\mathfrak{g}] = C^m\mathfrak{g} = 0$, $C^{m-1}\mathfrak{g} \subseteq \mathfrak{z}(\mathfrak{g})$. If $C^m(\mathfrak{g}/\mathfrak{z}(\mathfrak{g})) = 0$, then $C^m\mathfrak{g} \subseteq \mathfrak{z}(\mathfrak{g})$ and $C^{m+1}\mathfrak{g} = [\mathfrak{g}, C^m\mathfrak{g}] = 0$. □

Example 13.5.3. Let $\mathfrak{b}_n \subseteq \mathfrak{gl}_n(k)$ be the upper triangular matrices, $\mathfrak{n}_n$ the strictly upper triangular ones and $\mathfrak{d}_n$ the diagonal ones; all three are Lie subalgebras.

1. $\mathfrak{n}_n$ is nilpotent. Let $\mathfrak{n}^{(j)}$ be the matrices (a_{il}) with $a_{il} = 0$ unless $l - i \geq j$, so that $\mathfrak{n}_n = \mathfrak{n}^{(1)}$ and $\mathfrak{n}^{(n)} = 0$. The entry $(AB)_{il} = \sum_m a_{im}b_{ml}$ of a product of $A \in \mathfrak{n}^{(j)}$ and $B \in \mathfrak{n}^{(j')}$ can be nonzero only if $m - i \geq j$ and $l - m \geq j'$ for some m, so $AB \in \mathfrak{n}^{(j+j')}$. Hence $[\mathfrak{n}^{(1)}, \mathfrak{n}^{(j)}] \subseteq \mathfrak{n}^{(j+1)}$, and $C^i\mathfrak{n}_n \subseteq \mathfrak{n}^{(i)}$ vanishes for $i \geq n$.

2. $\mathfrak{b}_n$ is solvable: the diagonal of a product of upper triangular matrices is the product of the diagonals, so the diagonal of a commutator vanishes and $[\mathfrak{b}_n, \mathfrak{b}_n] \subseteq \mathfrak{n}_n$, which is solvable by (1) and Lemma 13.5.2(1); so $D^{m+1}\mathfrak{b}_n \subseteq D^m\mathfrak{n}_n$ vanishes for large m. For $n \geq 2$ it is not nilpotent: with the matrix units E_{il}, $[E_{11}, E_{12}] = E_{12}$, so $E_{12} \in C^i\mathfrak{b}_n$ for all i.

3. The two-dimensional Lie algebra with basis x, y and $[x, y] = y$ (for instance $x = E_{11}$, $y = E_{12}$ in $\mathfrak{b}_2$) is solvable, with $D^1 = ky$ and $D^2 = 0$, but not nilpotent, since $C^i = ky$ for all $i \geq 2$. The *Heisenberg algebra* $\mathfrak{n}_3$, with basis E_{12}, E_{23}, E_{13} and the only nonzero bracket $[E_{12}, E_{23}] = E_{13}$, is nilpotent but not abelian.

4. If $2 \neq 0$ in k, $\mathfrak{sl}_2(k)$ is not solvable: its basis $e = E_{12}$, $f = E_{21}$, $h = E_{11} - E_{22}$ satisfies $[h, e] = 2e$, $[h, f] = -2f$ and $[e, f] = h$, so $[\mathfrak{sl}_2, \mathfrak{sl}_2] = \mathfrak{sl}_2$ and $D^i\mathfrak{sl}_2 = \mathfrak{sl}_2$ for all i.

Lemma 13.5.4. *If $x \in \mathfrak{gl}(V)$ is nilpotent, then* $\operatorname{ad} x \colon \mathfrak{gl}(V) \to \mathfrak{gl}(V)$ *is nilpotent.*

Proof. Write $\operatorname{ad} x = \lambda_x - \rho_x$ with $\lambda_x(y) = xy$ and $\rho_x(y) = yx$. These two linear maps commute, by associativity, and if $x^m = 0$ then $\lambda_x^m = \lambda_{x^m} = 0$ and $\rho_x^m = 0$. By the binomial formula for commuting maps, $(\lambda_x - \rho_x)^{2m} = \sum_i \binom{2m}{i} \lambda_x^i (-\rho_x)^{2m-i}$, and every term has $i \geq m$ or $2m - i \geq m$, hence vanishes. □

Theorem 13.5.5 (Engel's theorem, linear form)**.** *Let $V \neq 0$ be a finite-dimensional vector space over any field k, and $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ a Lie subalgebra consisting of nilpotent endomorphisms. Then there is $v \neq 0$ in V with $xv = 0$ for all $x \in \mathfrak{g}$. Consequently V has a basis in which every element of $\mathfrak{g}$ is strictly upper triangular.*

Proof. Induction on $\dim \mathfrak{g}$. If $\mathfrak{g} = 0$ any $v \neq 0$ works, and if $\dim \mathfrak{g} = 1$, $\mathfrak{g} = kx$ with x nilpotent, and any nonzero $v \in \ker x$ works ($\ker x \neq 0$, as x is not invertible). Let $\dim \mathfrak{g} \geq 2$ and let $\mathfrak{h}$ be a proper subalgebra of maximal dimension (for instance 0 is proper).

Step 1: $\mathfrak{h}$ is an ideal of codimension 1. Since $[\mathfrak{h}, \mathfrak{h}] \subseteq \mathfrak{h}$, each $\operatorname{ad} h$, $h \in \mathfrak{h}$, preserves $\mathfrak{h}$ and induces an endomorphism $\overline{\operatorname{ad} h}$ of the nonzero space $\mathfrak{g}/\mathfrak{h}$; by the Jacobi identity $h \mapsto \overline{\operatorname{ad} h}$ is a homomorphism of Lie algebras $\mathfrak{h} \to \mathfrak{gl}(\mathfrak{g}/\mathfrak{h})$. Each $\operatorname{ad} h$ is nilpotent on $\mathfrak{gl}(V)$ (Lemma 13.5.4), hence on the invariant subspace $\mathfrak{g}$ and on the quotient $\mathfrak{g}/\mathfrak{h}$. So the image of $\mathfrak{h}$ is a Lie algebra of nilpotent endomorphisms of $\mathfrak{g}/\mathfrak{h}$ of dimension at most $\dim \mathfrak{h} < \dim \mathfrak{g}$, and by induction there is $y \in \mathfrak{g} \setminus \mathfrak{h}$ with $[h, y] \in \mathfrak{h}$ for all $h \in \mathfrak{h}$. Then $\mathfrak{h} + ky$ is a subalgebra strictly containing $\mathfrak{h}$, so it is $\mathfrak{g}$ by maximality; hence $\mathfrak{g} = \mathfrak{h} \oplus ky$ and $\mathfrak{h}$ is an ideal.

Step 2: a common null vector. By induction applied to $\mathfrak{h} \subseteq \mathfrak{gl}(V)$, the space $W = \{v \in V : hv = 0 \text{ for all } h \in \mathfrak{h}\}$ is nonzero. It is stable under y: for $w \in W$ and $h \in \mathfrak{h}$, $h(yw) = y(hw) + [h, y]w = 0$, as $[h, y] \in \mathfrak{h}$. The restriction of the nilpotent y to W is nilpotent, so it kills some $v \neq 0$ in W, and then $xv = 0$ for all $x \in \mathfrak{h} + ky = \mathfrak{g}$.

Step 3: the basis. Let v_1 be as above. Each $x \in \mathfrak{g}$ induces a nilpotent endomorphism of V/kv_1, and these form a Lie algebra of nilpotent endomorphisms; by induction on $\dim V$, V/kv_1 has a basis $\bar{v}_2, \dots, \bar{v}_d$ in which they are strictly upper triangular. Lifting it to $v_2, \dots, v_d$, we get $xv_1 = 0$ and $xv_j \in \operatorname{span}(v_1, \dots, v_{j-1})$, which is the claim. □

Corollary 13.5.6 (Engel's theorem)**.** *A Lie algebra $\mathfrak{g}$ is nilpotent if and only if* $\operatorname{ad} x$ *is nilpotent for every $x \in \mathfrak{g}$.*

Proof. If $C^m\mathfrak{g} = 0$, then $\operatorname{ad} x$ maps $C^i\mathfrak{g}$ into $C^{i+1}\mathfrak{g}$, so $(\operatorname{ad} x)^{m-1}\mathfrak{g} \subseteq C^m\mathfrak{g} = 0$. Conversely, the image $\operatorname{ad} \mathfrak{g} \subseteq \mathfrak{gl}(\mathfrak{g})$ is a Lie algebra of nilpotent endomorphisms. Theorem 13.5.5 gives a basis $v_1, \dots, v_d$ of $\mathfrak{g}$ such that, with $V_j = \operatorname{span}(v_1, \dots, v_j)$, $[\mathfrak{g}, V_j] \subseteq V_{j-1}$. By induction $C^i\mathfrak{g} \subseteq V_{d-i+1}$, since $C^1\mathfrak{g} = V_d$ and $C^{i+1}\mathfrak{g} = [\mathfrak{g}, C^i\mathfrak{g}] \subseteq [\mathfrak{g}, V_{d-i+1}] \subseteq V_{d-i}$. So $C^{d+1}\mathfrak{g} = 0$. □

Counterexample 13.5.7. 1. A nilpotent Lie algebra of matrices need not consist of nilpotent matrices: the diagonal matrices $\mathfrak{d}_n$ form an abelian, hence nilpotent, Lie algebra containing the identity. Engel's theorem is about the operators $\operatorname{ad} x$ on $\mathfrak{g}$, not about the matrices x on V.

2. In Theorem 13.5.5 it matters that $\mathfrak{g}$ is closed under brackets. The matrices $e = E_{12}$ and $f = E_{21}$ of $\mathfrak{sl}_2$ are nilpotent, but $\ker e = ke_1$ and $\ker f = ke_2$ meet only in 0; the Lie algebra they generate contains $[e, f] = h$, which is not nilpotent.

For Lie's theorem we need eigenvectors, hence an algebraically closed field, and characteristic 0. The key step is the following lemma.

Lemma 13.5.8 (Invariance lemma)**.** *Let k have characteristic 0, let $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ be a Lie subalgebra, $\mathfrak{a}$ an ideal of $\mathfrak{g}$ and $\lambda\colon \mathfrak{a} \to k$ a linear form. Then $W = \{v \in V : av = \lambda(a)v \text{ for all } a \in \mathfrak{a}\}$ is stable under $\mathfrak{g}$.*

Proof. Let $w \in W$ and $x \in \mathfrak{g}$. For $a \in \mathfrak{a}$, $a(xw) = x(aw) + [a, x]w = \lambda(a)xw + \lambda([a, x])w$, as $[a, x] \in \mathfrak{a}$. So it suffices to show $\lambda([a, x]) = 0$ for all a, when $W \neq 0$. Fix $w \neq 0$ in W, let $W_i = \operatorname{span}(w, xw, \dots, x^{i-1}w)$ (with $W_0 = 0$), and let $m \geq 1$ be least with $W_{m+1} = W_m$; then $w, xw, \dots, x^{m-1}w$ is a basis of W_m, and $xW_m \subseteq W_m$.

We claim that $ax^iw \in \lambda(a)x^iw + W_i$ for all $a \in \mathfrak{a}$ and $i \geq 0$. For $i = 0$ this is $aw = \lambda(a)w$. If it holds for $i - 1$ and all a, then $ax^iw = x(ax^{i-1}w) + [a, x]x^{i-1}w$. By induction $ax^{i-1}w = \lambda(a)x^{i-1}w + u$ with $u \in W_{i-1}$, so $x(ax^{i-1}w) \in \lambda(a)x^iw + W_i$; and $[a, x]x^{i-1}w \in \lambda([a, x])x^{i-1}w + W_{i-1} \subseteq W_i$. This proves the claim.

So each $a \in \mathfrak{a}$ maps W_m into itself, by an upper triangular matrix in the basis $w, xw, \dots, x^{m-1}w$ with all diagonal entries $\lambda(a)$, and $\operatorname{tr}(a|_{W_m}) = m\lambda(a)$. Apply this to $[a, x] \in \mathfrak{a}$: since a and x both preserve W_m, $[a, x]|_{W_m}$ is the commutator of $a|_{W_m}$ and $x|_{W_m}$, which has trace 0. So $m\lambda([a, x]) = 0$, and $\lambda([a, x]) = 0$ as $m \neq 0$ in k. □

Theorem 13.5.9 (Lie's theorem)**.** *Let k be algebraically closed of characteristic 0, $V \neq 0$ a finite-dimensional vector space and $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ a solvable Lie subalgebra. Then the elements of $\mathfrak{g}$ have a common eigenvector: there are $v \neq 0$ and a linear form λ on $\mathfrak{g}$ with $xv = \lambda(x)v$ for all $x \in \mathfrak{g}$. Consequently V has a basis in which every element of $\mathfrak{g}$ is upper triangular.*

Proof. Induction on $\dim \mathfrak{g}$; for $\mathfrak{g} = 0$ take any $v \neq 0$ and $\lambda = 0$. Let $\mathfrak{g} \neq 0$. Then $[\mathfrak{g}, \mathfrak{g}] \neq \mathfrak{g}$, since otherwise $D^i\mathfrak{g} = \mathfrak{g}$ for all i. Choose a subspace $\mathfrak{a}$ of codimension 1 containing $[\mathfrak{g}, \mathfrak{g}]$. It is an ideal, as $[\mathfrak{g}, \mathfrak{a}] \subseteq [\mathfrak{g}, \mathfrak{g}] \subseteq \mathfrak{a}$, and it is solvable (Lemma 13.5.2(2)). By induction there are $v_0 \neq 0$ and $\lambda\colon \mathfrak{a} \to k$ with $av_0 = \lambda(a)v_0$ for $a \in \mathfrak{a}$, so the space W of Lemma 13.5.8 is nonzero, and it is stable under $\mathfrak{g}$. Write $\mathfrak{g} = \mathfrak{a} \oplus kz$. As k is algebraically closed, $z|_W$ has an eigenvector $v \in W$, $zv = \mu v$. Then v is an eigenvector of every element of $\mathfrak{g}$, with λ extended by $\lambda(z) = \mu$. The basis is obtained as in Step 3 of the proof of Theorem 13.5.5, applying the first part to V/kv. □

Corollary 13.5.10. *Let k be algebraically closed of characteristic 0 and $\mathfrak{g}$ solvable.*

1. *Every irreducible representation of $\mathfrak{g}$ is one-dimensional.*

2. *There is a chain of ideals $0 = \mathfrak{g}_0 \subset \mathfrak{g}_1 \subset \cdots \subset \mathfrak{g}_d = \mathfrak{g}$ with $\dim \mathfrak{g}_i = i$.*

3. *$[\mathfrak{g}, \mathfrak{g}]$ is nilpotent. Conversely, over any field, a Lie algebra $\mathfrak{g}$ with $[\mathfrak{g}, \mathfrak{g}]$ nilpotent is solvable.*

Proof. (1) The image of $\mathfrak{g}$ in $\mathfrak{gl}(V)$ is solvable (Lemma 13.5.2(2)), so it has a common eigenvector v, and kv is a subrepresentation, hence equal to V. (2) Apply Theorem 13.5.9 to $\operatorname{ad} \mathfrak{g} \subseteq \mathfrak{gl}(\mathfrak{g})$: in the resulting basis $v_1, \dots, v_d$, the spans $\mathfrak{g}_i = \operatorname{span}(v_1, \dots, v_i)$ satisfy $[\mathfrak{g}, \mathfrak{g}_i] \subseteq \mathfrak{g}_i$. (3) In the

same basis every $\operatorname{ad} x$ is upper triangular, so every $\operatorname{ad}[x,y] = [\operatorname{ad} x, \operatorname{ad} y]$ is strictly upper triangular, as is every element of $\operatorname{ad}[\mathfrak{g},\mathfrak{g}]$; hence for $z \in [\mathfrak{g},\mathfrak{g}]$, $\operatorname{ad} z$ is nilpotent on $\mathfrak{g}$, and so on the invariant subspace $[\mathfrak{g},\mathfrak{g}]$. By Corollary 13.5.6, $[\mathfrak{g},\mathfrak{g}]$ is nilpotent. Conversely, if $[\mathfrak{g},\mathfrak{g}]$ is nilpotent it is solvable, and $\mathfrak{g}/[\mathfrak{g},\mathfrak{g}]$ is abelian, so $\mathfrak{g}$ is solvable by Lemma 13.5.2(3). □

Counterexample 13.5.11. Both hypotheses on k are needed in Theorem 13.5.9.

1. Over $\mathbb{R}$, the abelian Lie algebra spanned by the rotation generator $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ has no eigenvector in $\mathbb{R}^2$.
2. Let k be algebraically closed of characteristic $p > 0$, and $V = k^p$ with basis $e_0, \dots, e_{p-1}$, indices modulo p. Let $xe_i = ie_i$ and $ye_i = e_{i+1}$. Then $[x,y]e_i = (i+1)e_{i+1} - ie_{i+1} = ye_i$, so $[x,y] = y$ and $\mathfrak{g} = kx + ky$ is solvable (Example 13.5.3(3)). But x and y have no common eigenvector. An eigenvector $v = \sum_i c_i e_i$ of y with eigenvalue μ satisfies $c_{i-1} = \mu c_i$ for all i, hence $c_i = \mu^p c_i$ and $\mu^p = 1$, that is $(\mu - 1)^p = 0$ and $\mu = 1$; so v is a multiple of $\sum_i e_i$, and $xv = \sum_i ie_i$ is not a multiple of v since $p \geq 2$. In the proof of Lemma 13.5.8 the argument breaks down at $m\lambda([a,x]) = 0$, with $m = p$.

Remark 13.5.12. Every Lie algebra $\mathfrak{g}$ has a largest solvable ideal, the *radical* (the sum of two solvable ideals is solvable by Lemma 13.5.2(3), as $(\mathfrak{a}+\mathfrak{b})/\mathfrak{a} \cong \mathfrak{b}/(\mathfrak{a}\cap\mathfrak{b})$), and $\mathfrak{g}$ is *semisimple* if its radical is 0. Over a field of characteristic 0, *Cartan's criterion* characterises solvability by the trace form: $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ is solvable if and only if $\operatorname{tr}(xy) = 0$ for all $x \in \mathfrak{g}$ and $y \in [\mathfrak{g},\mathfrak{g}]$; and $\mathfrak{g}$ is semisimple if and only if its Killing form $\operatorname{tr}(\operatorname{ad} x \operatorname{ad} y)$ is nondegenerate. Both are proved in Section 13.7 (Theorems 13.7.6 and 13.7.8), using Lie's theorem and the Jordan–Chevalley decomposition (Theorem 11.8.11). For example $\mathfrak{sl}_2(\mathbb{C})$ is semisimple, and Theorem 13.6.3 below is the first case of Weyl's theorem (Theorem 13.8.2).

13.6 Representations of $\mathfrak{sl}_2$

In this section $k = \mathbb{C}$ and $\mathfrak{sl}_2 = \mathfrak{sl}_2(\mathbb{C})$, with basis

$$e = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad f = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \qquad h = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

satisfying $[h,e] = 2e$, $[h,f] = -2f$ and $[e,f] = h$. All representations are finite-dimensional.

Lemma 13.6.1. *Let V be a representation and for $\lambda \in \mathbb{C}$ let $V_\lambda = \ker(h-\lambda)$ and $V^{(\lambda)} = \bigcup_N \ker(h-\lambda)^N$ (the generalised eigenspace). Then e maps V_λ to $V_{\lambda+2}$ and $V^{(\lambda)}$ to $V^{(\lambda+2)}$, and f maps them to $V_{\lambda-2}$ and $V^{(\lambda-2)}$. Moreover, for $k \geq 1$,*

$$ef^k = f^k e + kf^{k-1}(h-k+1) \quad \text{as operators on } V.$$

Proof. From $he = eh+2e$ we get $(h-\lambda-2)e = e(h-\lambda)$, hence $(h-\lambda-2)^N e = e(h-\lambda)^N$; similarly for f. The identity holds for $k = 1$ since $ef = fe+h$. If it holds for k, then using $hf = fh-2f$, $ef^{k+1} = f^k ef + kf^{k-1}(h-k+1)f = f^k(fe+h) + kf^k(h-k-1) = f^{k+1}e + (k+1)f^k(h-k)$. □

Theorem 13.6.2. *For every $m \geq 0$ there is an irreducible representation $V(m)$ of dimension $m+1$ with a basis $v_0, \dots, v_m$ such that*

$$hv_j = (m-2j)v_j, \qquad fv_j = (j+1)v_{j+1}, \qquad ev_j = (m-j+1)v_{j-1},$$

with $v_{-1} = v_{m+1} = 0$. Every irreducible representation is isomorphic to exactly one $V(m)$. More precisely, if V is any representation and $v_0 \neq 0$ satisfies $ev_0 = 0$ and $hv_0 = \lambda v_0$, then $\lambda = m$ is a non-negative integer and the vectors $v_j = f^j v_0/j!$ span a subrepresentation isomorphic to $V(m)$.

Proof. The formulas define a representation: it suffices to check the three bracket relations on each v_j. For instance $(ef - fe)v_j = (j+1)(m-j)v_j - j(m-j+1)v_j = (m-2j)v_j = hv_j$, and $[h,e] = 2e$, $[h,f] = -2f$ hold because e raises and f lowers the h-eigenvalue by 2. It is irreducible: a nonzero subrepresentation is h-stable, so it contains some v_j (the eigenvalues $m-2j$ are distinct), then v_0 by applying e (the coefficients $m-j+1$ are nonzero for $1 \le j \le m$), then all v_j by applying f.

Now let v_0 be as in the last statement and $v_j = f^j v_0/j!$. By Lemma 13.6.1, $hv_j = (\lambda - 2j)v_j$, and $fv_j = (j+1)v_{j+1}$ by definition. By the identity of the lemma, $ev_j = \frac{1}{j!} j f^{j-1}(h-j+1)v_0 = (\lambda - j + 1)v_{j-1}$. The nonzero v_j have distinct h-eigenvalues, hence are linearly independent, so there is a largest m with $v_m \neq 0$, and then $v_{m+1} = 0$. Hence $0 = ev_{m+1} = (\lambda - m)v_m$, so $\lambda = m$, and the span of $v_0, \dots, v_m$ is a subrepresentation isomorphic to $V(m)$.

Every representation $V \neq 0$ contains such a v_0: h has an eigenvector w, with eigenvalue μ, and among $w, ew, e^2w, \dots$ (which lie in the distinct eigenspaces $V_{\mu+2i}$ or vanish) there is a last nonzero one. If V is irreducible, the subrepresentation generated by v_0 is all of V, so $V \cong V(m)$ with $m = \dim V - 1$. □

Theorem 13.6.3. *Every finite-dimensional representation of* $\mathfrak{sl}_2$ *is completely reducible, and* h *acts diagonalisably with integer eigenvalues.*

Proof. Let $C = ef + fe + \frac{1}{2}h^2$ (the *Casimir operator*). A direct computation with the relations shows that C commutes with e, f and h; for example $[C,e] = e[f,e] + [f,e]e + \frac{1}{2}(h[h,e] + [h,e]h) = -eh - he + eh + he = 0$. On $V(m)$, C is scalar by Lemma 13.2.3, and evaluating on v_0 gives $C = m + \frac{1}{2}m^2 = \frac{1}{2}m(m+2)$ (using $efv_0 = mv_0$ and $ev_0 = 0$). These scalars are distinct for different $m \ge 0$.

Since C commutes with the action, V is the direct sum of the generalised eigenspaces of C, each of which is a subrepresentation (Lemma 11.7.5). By choosing an irreducible subrepresentation and passing to quotients repeatedly, every representation has a chain of subrepresentations with irreducible successive quotients, each isomorphic to some $V(m)$ by Theorem 13.6.2; C acts on the quotient $V(m)$ by $\frac{1}{2}m(m+2)$. Hence on the generalised c-eigenspace, all these quotients are isomorphic to the same $V(m)$ (with $c = \frac{1}{2}m(m+2)$). It therefore suffices to prove: if V has such a chain $0 = F_0 \subsetneq F_1 \subsetneq \cdots \subsetneq F_r = V$ with $F_i/F_{i-1} \cong V(m)$ for all i, then $V \cong V(m)^r$.

The eigenvalues of h on V are among $m, m-2, \dots, -m$, so $V^{(m+2)} = 0$ and e kills $V^{(m)}$ (Lemma 13.6.1). Also $\dim V^{(m)} = r$, since each quotient contributes one dimension. The map $f^m \colon V^{(m)} \to V^{(-m)}$ is injective: if $u \in V^{(m)}$ is nonzero, let i be least with $u \in F_i$; the image of u in $F_i/F_{i-1} \cong V(m)$ is a nonzero vector of weight m, on which f^m is nonzero, so $f^m u \notin F_{i-1}$. Now $f^{m+1}u \in V^{(-m-2)} = 0$, and by Lemma 13.6.1, $0 = ef^{m+1}u = f^{m+1}eu + (m+1)f^m(h-m)u = (m+1)f^m(h-m)u$. Since $(h-m)u \in V^{(m)}$ and f^m is injective there, $(h-m)u = 0$. So $h = m$ on $V^{(m)}$.

Let $u_1, \dots, u_r$ be a basis of $V^{(m)} = V_m$. Each u_i satisfies $eu_i = 0$ and $hu_i = mu_i$, so it generates a subrepresentation $W_i \cong V(m)$ by Theorem 13.6.2. The kernel K of $\bigoplus_i W_i \to V$ is a subrepresentation whose weight-m part is zero, since the u_i are independent. If $K \neq 0$, the last paragraph of the proof of Theorem 13.6.2, applied to K, gives $v_0 \in K$ with $v_0 \neq 0$ and $ev_0 = 0$. But in $V(m)$ the kernel of e is $\mathbb{C}v_0$, since $e(\sum_j c_j v_j) = \sum_{j \ge 1} c_j (m-j+1)v_{j-1}$ vanishes only if $c_j = 0$ for $j \ge 1$; so in $\bigoplus_i W_i \cong V(m)^r$ the kernel of e is the weight-m space, and v_0 would be a nonzero element of K of weight m. Hence $K = 0$, the sum is direct, and by dimension ($r(m+1) = \dim V$) it is all of V. In each W_i, h is diagonal with integer eigenvalues. □

Corollary 13.6.4. *Let* V *be a finite-dimensional representation of* $\mathfrak{sl}_2$*, with weight spaces* $V_\lambda = \ker(h - \lambda)$*,* $\lambda \in \mathbb{Z}$*. For every* $j \ge 0$ *the map* $f^j \colon V_j \to V_{-j}$ *is an isomorphism. Let* $P_j = V_j \cap \ker e$

(the primitive *vectors of weight j). Then*

$$V = \bigoplus_{j \geq 0} \bigoplus_{i=0}^{j} f^i P_j,$$

and f^i is injective on P_j for $0 \leq i \leq j$.

Proof. By Theorem 13.6.3 it suffices to treat $V = V(m)$, where $V_{m-2i} = \mathbb{C}v_i$, f^j maps $v_{(m-j)/2}$ to a nonzero multiple of $v_{(m+j)/2}$ when $m - j$ is even and non-negative, $P_m = \mathbb{C}v_0$, $P_j = 0$ for $j \neq m$, and $f^i P_m = \mathbb{C}v_i$. □

Remark 13.6.5. Theorem 13.6.3 is a special case of Weyl's theorem (Theorem 13.8.2): every finite-dimensional representation of a semisimple Lie algebra over a field of characteristic 0 is completely reducible. The irreducible representations are classified by their highest weights (Section 13.11), and the semisimple Lie algebras themselves by Dynkin diagrams (Section 13.10). The theory of $\mathfrak{sl}_2$ is also the main tool of that classification: every semisimple Lie algebra is built from copies of $\mathfrak{sl}_2$, one for each pair of roots $\pm\alpha$ (Proposition 13.9.5). See [Hum72] and [FH91].

13.7 Semisimple Lie algebras

By Lie's theorem a solvable Lie algebra over $\mathbb{C}$ is, in a suitable basis of any representation, an algebra of upper triangular matrices: it is as close to being abelian as a nonabelian Lie algebra can be. Semisimple Lie algebras are the opposite extreme: they have no nonzero solvable ideals at all. Every Lie algebra $\mathfrak{g}$ is an extension of the semisimple Lie algebra $\mathfrak{g}/\operatorname{rad}\mathfrak{g}$ by its largest solvable ideal $\operatorname{rad}\mathfrak{g}$ (Lemma 13.7.2), so the two classes together describe all Lie algebras. This section and the next four develop the structure of semisimple Lie algebras:

1. the Killing form and Cartan's criteria for solvability and semisimplicity; the decomposition into simple ideals; derivations; the abstract Jordan decomposition (this section);
2. Weyl's theorem on complete reducibility (Section 13.8);
3. the root space decomposition with respect to a Cartan subalgebra, built from copies of $\mathfrak{sl}_2$ (Section 13.9);
4. root systems, Weyl groups, Dynkin diagrams and the classification (Section 13.10);
5. weights and highest weights of representations (Section 13.11).

We follow [Hum72, Chapters II–III and VI]. Throughout these sections, k is a field of characteristic 0, so that $\mathbb{Q} \subseteq k$, and Lie algebras and representations are finite-dimensional.

Definition 13.7.1. Let $\mathfrak{g}$ be a Lie algebra.

1. The *radical* $\operatorname{rad}\mathfrak{g}$ is the largest solvable ideal of $\mathfrak{g}$ (it exists by Lemma 13.7.2 below). $\mathfrak{g}$ is *semisimple* if $\operatorname{rad}\mathfrak{g} = 0$, and *simple* if it is not abelian and its only ideals are 0 and $\mathfrak{g}$.
2. For a representation $\varphi\colon \mathfrak{g} \to \mathfrak{gl}(V)$, the *trace form* of φ is the symmetric bilinear form $\beta_\varphi(x, y) = \operatorname{tr}(\varphi(x)\varphi(y))$ on $\mathfrak{g}$. The trace form of the adjoint representation is the *Killing form*
$$\kappa(x, y) = \kappa_{\mathfrak{g}}(x, y) = \operatorname{tr}(\operatorname{ad} x \circ \operatorname{ad} y).$$

Lemma 13.7.2. *Let $\mathfrak{g}$ be a Lie algebra.*

1. *The sum of two solvable ideals is a solvable ideal. Hence* $\mathfrak{g}$ *has a largest solvable ideal* $\operatorname{rad}\mathfrak{g}$*, and* $\mathfrak{g}/\operatorname{rad}\mathfrak{g}$ *is semisimple.*

2. $\mathfrak{g}$ *is semisimple if and only if it has no nonzero abelian ideal. In particular a semisimple Lie algebra has centre* 0*. A simple Lie algebra* $\mathfrak{g}$ *satisfies* $[\mathfrak{g},\mathfrak{g}] = \mathfrak{g}$ *and is semisimple.*

3. *Every trace form is* invariant*:* $\beta_\varphi([x,y],z) = \beta_\varphi(x,[y,z])$*. Consequently the orthogonal* $\mathfrak{a}^\perp = \{x : \beta_\varphi(x,\mathfrak{a}) = 0\}$ *of an ideal* $\mathfrak{a}$ *is an ideal.*

4. *If* $\mathfrak{a}$ *is an ideal of* $\mathfrak{g}$*, the Killing form of the Lie algebra* $\mathfrak{a}$ *is the restriction of* $\kappa_\mathfrak{g}$ *to* $\mathfrak{a}\times\mathfrak{a}$*.*

Proof. (1) Let $\mathfrak{a}$, $\mathfrak{b}$ be solvable ideals. Then $\mathfrak{a}+\mathfrak{b}$ is an ideal, and $(\mathfrak{a}+\mathfrak{b})/\mathfrak{a} \cong \mathfrak{b}/(\mathfrak{a}\cap\mathfrak{b})$ is a homomorphic image of $\mathfrak{b}$, hence solvable (Lemma 13.5.2(2)); so $\mathfrak{a}+\mathfrak{b}$ is solvable by Lemma 13.5.2(3). A solvable ideal of maximal dimension therefore contains every solvable ideal. If $\bar{\mathfrak{a}}$ is a solvable ideal of $\mathfrak{g}/\operatorname{rad}\mathfrak{g}$, its preimage $\mathfrak{a}$ is an ideal of $\mathfrak{g}$ with $\mathfrak{a}/\operatorname{rad}\mathfrak{g}$ solvable, hence solvable, so $\mathfrak{a}\subseteq\operatorname{rad}\mathfrak{g}$ and $\bar{\mathfrak{a}}=0$.

(2) Abelian ideals are solvable. Conversely, if $\mathfrak{r} = \operatorname{rad}\mathfrak{g} \neq 0$, let m be largest with $D^m\mathfrak{r}\neq 0$. By Lemma 13.5.2(1), applied repeatedly, each $D^i\mathfrak{r}$ is an ideal of $\mathfrak{g}$, and $[D^m\mathfrak{r}, D^m\mathfrak{r}] = D^{m+1}\mathfrak{r} = 0$; so $D^m\mathfrak{r}$ is a nonzero abelian ideal. The centre is an abelian ideal. If $\mathfrak{g}$ is simple, $[\mathfrak{g},\mathfrak{g}]$ is an ideal, nonzero as $\mathfrak{g}$ is not abelian, so $[\mathfrak{g},\mathfrak{g}]=\mathfrak{g}$; an abelian ideal is then 0, since $\mathfrak{g}$ itself is not abelian.

(3) For endomorphisms X, Y, Z, $\operatorname{tr}([X,Y]Z) = \operatorname{tr}(XYZ) - \operatorname{tr}(YXZ) = \operatorname{tr}(XYZ) - \operatorname{tr}(XZY) = \operatorname{tr}(X[Y,Z])$, using $\operatorname{tr}(AB) = \operatorname{tr}(BA)$. Apply this to $X=\varphi(x)$, $Y=\varphi(y)$, $Z=\varphi(z)$, and use $\varphi([x,y]) = [\varphi(x),\varphi(y)]$. If $z\in\mathfrak{a}^\perp$, $x\in\mathfrak{g}$ and $a\in\mathfrak{a}$, then $\beta_\varphi([x,z],a) = -\beta_\varphi([z,x],a) = -\beta_\varphi(z,[x,a]) = 0$, since $[x,a]\in\mathfrak{a}$.

(4) If an endomorphism ϕ of a finite-dimensional space U maps U into a subspace W, then $\operatorname{tr}\phi = \operatorname{tr}(\phi|_W)$: in a basis of U extending one of W, the rows of the matrix of ϕ belonging to the added vectors are zero. For $x,y\in\mathfrak{a}$, $\operatorname{ad}x\circ\operatorname{ad}y$ maps $\mathfrak{g}$ into $\mathfrak{a}$, and its restriction to $\mathfrak{a}$ is $\operatorname{ad}_\mathfrak{a} x\circ\operatorname{ad}_\mathfrak{a} y$. □

Remark 13.7.3. *Levi's theorem* says that the extension $0\to\operatorname{rad}\mathfrak{g}\to\mathfrak{g}\to\mathfrak{g}/\operatorname{rad}\mathfrak{g}\to 0$ splits: $\mathfrak{g}$ contains a semisimple subalgebra $\mathfrak{s}$ mapping isomorphically onto $\mathfrak{g}/\operatorname{rad}\mathfrak{g}$, so that $\mathfrak{g} = \operatorname{rad}\mathfrak{g}\oplus\mathfrak{s}$ as vector spaces, with $\mathfrak{s}$ acting on the ideal $\operatorname{rad}\mathfrak{g}$; see [FH91, Appendix E]. For example $\mathfrak{gl}_n(k) = k\cdot I\oplus\mathfrak{sl}_n(k)$, where the radical $k\cdot I$ is the centre (Example 13.7.9). We do not use Levi's theorem.

The key tool is the following refinement of the Jordan–Chevalley decomposition, and its consequence for traces.

Lemma 13.7.4. *Let* k *be algebraically closed,* V *finite-dimensional,* $x\in\mathfrak{gl}(V)$*, and* $x = s+n$ *its Jordan–Chevalley decomposition (Theorem 11.8.11).*

1. *There are polynomials* $p,q\in k[T]$ *without constant term such that* $s=p(x)$ *and* $n=q(x)$*. Hence if* $A\subseteq B\subseteq V$ *are subspaces with* $x(B)\subseteq A$*, then* $s(B)\subseteq A$ *and* $n(B)\subseteq A$*.*

2. *If* $v_1,\dots,v_m$ *is a basis of* V *with* $sv_i = a_iv_i$ *and* E_{ij} *are the corresponding matrix units* $(E_{ij}v_l = \delta_{jl}v_i)$*, then* $\operatorname{ad}s(E_{ij}) = (a_i-a_j)E_{ij}$*.*

3. $\operatorname{ad}x = \operatorname{ad}s + \operatorname{ad}n$ *is the Jordan–Chevalley decomposition of the endomorphism* $\operatorname{ad}x$ *of* $\mathfrak{gl}(V)$*.*

Proof. (1) In Step 1 of the proof of Theorem 11.8.11, $s=p(x)$ for any polynomial p with $p\equiv\lambda_i \bmod (T-\lambda_i)^{e_i}$ for all the distinct eigenvalues λ_i; by uniqueness (Step 2) this s is the semisimple part. If some λ_i is 0, this congruence already gives $p(0)=0$. Otherwise T is coprime to all $(T-\lambda_i)^{e_i}$, and the Chinese remainder theorem (Theorem 8.3.3) gives a p satisfying in addition $p\equiv 0 \bmod T$. Put $q = T-p$. If $x(B)\subseteq A\subseteq B$, then $x(A)\subseteq x(B)\subseteq A$,

so $x^j(B) \subseteq A$ for all $j \geq 1$, and the same holds for the polynomials $p(x)$ and $q(x)$ without constant term.

(2) $(sE_{ij} - E_{ij}s)v_l = \delta_{jl}(a_i - a_j)v_i$.

(3) Over an algebraically closed field semisimple endomorphisms are diagonalisable (Lemma 11.8.10), so a basis as in (2) exists, and by (2) $\operatorname{ad} s$ is diagonalisable in the basis (E_{ij}). The endomorphism $\operatorname{ad} n$ is nilpotent by Lemma 13.5.4, and $[\operatorname{ad} s, \operatorname{ad} n] = \operatorname{ad}[s, n] = 0$ by the Jacobi identity. By the uniqueness in Theorem 11.8.11, $\operatorname{ad} s$ and $\operatorname{ad} n$ are the semisimple and nilpotent parts of $\operatorname{ad} x = \operatorname{ad} s + \operatorname{ad} n$. □

Lemma 13.7.5. *Let k be algebraically closed, V finite-dimensional, $A \subseteq B$ subspaces of $\mathfrak{gl}(V)$, and $M = \{x \in \mathfrak{gl}(V) : [x, B] \subseteq A\}$. If $x \in M$ satisfies $\operatorname{tr}(xy) = 0$ for all $y \in M$, then x is nilpotent.*

Proof. Let $x = s + n$ be the Jordan–Chevalley decomposition and $v_1, \dots, v_m$ a basis with $sv_i = a_i v_i$. Let $E \subseteq k$ be the $\mathbb{Q}$-vector space spanned by $a_1, \dots, a_m$. We show $E = 0$; then all a_i vanish, $s = 0$, and $x = n$ is nilpotent. As E is finite-dimensional over $\mathbb{Q}$, it suffices to show that every $\mathbb{Q}$-linear map $f : E \to \mathbb{Q}$ is zero.

Given f, let $y \in \mathfrak{gl}(V)$ be defined by $yv_i = f(a_i)v_i$. By Lemma 13.7.4(2), $\operatorname{ad} y(E_{ij}) = (f(a_i) - f(a_j))E_{ij}$ and $\operatorname{ad} s(E_{ij}) = (a_i - a_j)E_{ij}$. The finitely many numbers $a_i - a_j$ and 0 can be assigned the values $f(a_i) - f(a_j)$ and 0 consistently: if $a_i - a_j = a_{i'} - a_{j'}$, then $f(a_i) - f(a_j) = f(a_i - a_j) = f(a_{i'}) - f(a_{j'})$ by $\mathbb{Q}$-linearity, and $a_i - a_j = 0$ gives the value 0. By Lagrange interpolation there is $r \in k[T]$ with $r(0) = 0$ and $r(a_i - a_j) = f(a_i) - f(a_j)$ for all i, j; then $\operatorname{ad} y = r(\operatorname{ad} s)$, since both are diagonal in the basis (E_{ij}) with the same entries. By Lemma 13.7.4(3) and (1), applied to $\operatorname{ad} x$, $\operatorname{ad} s = p(\operatorname{ad} x)$ for a polynomial p without constant term; so $\operatorname{ad} y = r(p(\operatorname{ad} x))$ is a polynomial in $\operatorname{ad} x$ without constant term. As $\operatorname{ad} x$ maps B into A, so does $\operatorname{ad} y$ (Lemma 13.7.4(1)), that is, $y \in M$, and the hypothesis gives $\operatorname{tr}(xy) = 0$.

Now $\operatorname{tr}(xy) = \operatorname{tr}(sy) + \operatorname{tr}(ny)$. In the basis (v_i), sy is diagonal with entries $a_i f(a_i)$. Interpolating again, $y = g(s)$ for a polynomial g with $g(a_i) = f(a_i)$, so y commutes with n, which commutes with s; hence ny is nilpotent ($(ny)^N = n^N y^N$) and has trace 0. Therefore $\sum_i a_i f(a_i) = 0$. The left side is an element of E, since $f(a_i) \in \mathbb{Q}$; applying f gives $\sum_i f(a_i)^2 = 0$, a sum of squares of rational numbers. So $f(a_i) = 0$ for all i, and $f = 0$. □

Theorem 13.7.6 (Cartan's criterion)**.** *Let V be a finite-dimensional vector space and $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ a Lie subalgebra such that $\operatorname{tr}(xy) = 0$ for all $x \in [\mathfrak{g}, \mathfrak{g}]$ and $y \in \mathfrak{g}$. Then $\mathfrak{g}$ is solvable.*

Proof. Reduction to k algebraically closed. Choose a basis, so that $\mathfrak{g} \subseteq \mathfrak{gl}_d(k) \subseteq \mathfrak{gl}_d(\bar{k})$ for an algebraic closure $\bar{k}$ (Theorem 9.3.5), and let $\bar{\mathfrak{g}}$ be the $\bar{k}$-span of $\mathfrak{g}$. It is a Lie subalgebra, as the bracket is bilinear; $[\bar{\mathfrak{g}}, \bar{\mathfrak{g}}]$ is the $\bar{k}$-span of $[\mathfrak{g}, \mathfrak{g}]$, so the hypothesis holds for $\bar{\mathfrak{g}}$ by bilinearity of $\operatorname{tr}(xy)$. If $\bar{\mathfrak{g}}$ is solvable, so is its subalgebra $\mathfrak{g}$. So we may assume k algebraically closed.

The case k algebraically closed. It suffices to show that every $x \in [\mathfrak{g}, \mathfrak{g}]$ is a nilpotent endomorphism of V. Indeed, then $\operatorname{ad} x$ is nilpotent on $\mathfrak{gl}(V)$ (Lemma 13.5.4), hence on its invariant subspace $[\mathfrak{g}, \mathfrak{g}]$, so $[\mathfrak{g}, \mathfrak{g}]$ is nilpotent by Engel's theorem (Corollary 13.5.6), and $\mathfrak{g}$ is solvable by Corollary 13.5.10(3). Apply Lemma 13.7.5 with $A = [\mathfrak{g}, \mathfrak{g}]$ and $B = \mathfrak{g}$: then $M = \{y : [y, \mathfrak{g}] \subseteq [\mathfrak{g}, \mathfrak{g}]\}$ contains $\mathfrak{g}$. Let $x \in [\mathfrak{g}, \mathfrak{g}]$, a sum of brackets $[u, v]$ with $u, v \in \mathfrak{g}$, and $y \in M$. By the identity $\operatorname{tr}([u, v]y) = \operatorname{tr}(u[v, y])$ of Lemma 13.7.2(3), and since $[v, y] = -[y, v] \in [\mathfrak{g}, \mathfrak{g}]$, the hypothesis gives $\operatorname{tr}([u, v]y) = 0$. So $\operatorname{tr}(xy) = 0$ for all $y \in M$, and x is nilpotent by the lemma. □

Corollary 13.7.7. *A Lie algebra $\mathfrak{g}$ is solvable if and only if $\kappa(x, y) = 0$ for all $x \in [\mathfrak{g}, \mathfrak{g}]$ and $y \in \mathfrak{g}$.*

Proof. Suppose the Killing form vanishes on $[\mathfrak{g}, \mathfrak{g}] \times \mathfrak{g}$. Since $[\operatorname{ad} \mathfrak{g}, \operatorname{ad} \mathfrak{g}] = \operatorname{ad}[\mathfrak{g}, \mathfrak{g}]$, Cartan's criterion applied to $\operatorname{ad} \mathfrak{g} \subseteq \mathfrak{gl}(\mathfrak{g})$ shows that $\operatorname{ad} \mathfrak{g}$ is solvable. The kernel of ad is the centre, which is abelian, and $\mathfrak{g}/\mathfrak{z}(\mathfrak{g}) \cong \operatorname{ad} \mathfrak{g}$; so $\mathfrak{g}$ is solvable by Lemma 13.5.2(3).

Conversely, let $\mathfrak{g}$ be solvable, and let L be the $\bar{k}$-span of $\operatorname{ad}\mathfrak{g}$ in $\mathfrak{gl}_d(\bar{k})$, using a basis of $\mathfrak{g}$ and an algebraic closure $\bar{k}$. Then D^iL is the $\bar{k}$-span of $D^i(\operatorname{ad}\mathfrak{g}) = \operatorname{ad}(D^i\mathfrak{g})$, so L is solvable. By Lie's theorem (Theorem 13.5.9) there is a basis of $\bar{k}^d$ in which all elements of L are upper triangular; then the elements of $[L, L]$ are strictly upper triangular, and so is the product of an element of $[L, L]$ with an element of L. For $x \in [\mathfrak{g}, \mathfrak{g}]$ and $y \in \mathfrak{g}$, $\operatorname{ad} x \in [L, L]$, so $\kappa(x, y) = \operatorname{tr}(\operatorname{ad} x \operatorname{ad} y) = 0$. □

Theorem 13.7.8 (Cartan's criterion for semisimplicity)**.** *A Lie algebra is semisimple if and only if its Killing form is nondegenerate.*

Proof. Let $S = \mathfrak{g}^\perp = \{x : \kappa(x, \mathfrak{g}) = 0\}$ be the radical of the Killing form; it is an ideal by Lemma 13.7.2(3). The Killing form of S is the restriction of κ (Lemma 13.7.2(4)), which vanishes on $S \times S$; by Corollary 13.7.7, S is solvable, so $S \subseteq \operatorname{rad}\mathfrak{g}$. Hence if $\mathfrak{g}$ is semisimple, $S = 0$.

Conversely, suppose $\mathfrak{g}$ is not semisimple, and let $\mathfrak{a} \neq 0$ be an abelian ideal (Lemma 13.7.2(2)). For $a \in \mathfrak{a}$ and $y \in \mathfrak{g}$, $\operatorname{ad} a \operatorname{ad} y$ maps $\mathfrak{g}$ into $\mathfrak{a}$, and maps $\mathfrak{a}$ into $[a, \mathfrak{a}] = 0$; so $(\operatorname{ad} a \operatorname{ad} y)^2 = 0$ and $\kappa(a, y) = 0$. Thus $0 \neq \mathfrak{a} \subseteq S$, and κ is degenerate. □

Example 13.7.9.

1. $\mathfrak{gl}_n$ *and* $\mathfrak{sl}_n$. For $x, y \in \mathfrak{gl}_n(k)$, $\operatorname{ad} x \operatorname{ad} y(z) = xyz - xzy - yzx + zyx$. The map $z \mapsto xyz$ is left multiplication by xy, which acts on each of the n columns of z by xy, so its trace is $n \operatorname{tr}(xy)$; similarly $z \mapsto zyx$ has trace $n \operatorname{tr}(yx)$, and $z \mapsto xzy$ sends E_{ij} to $\sum_{l,m} x_{li}y_{jm}E_{lm}$, whose diagonal coefficient at E_{ij} is $x_{ii}y_{jj}$, so its trace is $\operatorname{tr} x \operatorname{tr} y$, as is that of $z \mapsto yzx$. Hence

$$\kappa_{\mathfrak{gl}_n}(x, y) = 2n \operatorname{tr}(xy) - 2 \operatorname{tr} x \operatorname{tr} y.$$

It is degenerate: $\kappa(I, y) = 2n \operatorname{tr} y - 2n \operatorname{tr} y = 0$. Indeed $k \cdot I$ is an abelian ideal, the centre. For $x, y \in \mathfrak{sl}_n(k)$, $\operatorname{ad} x \operatorname{ad} y$ maps $\mathfrak{gl}_n$ into $[\mathfrak{gl}_n, \mathfrak{gl}_n] \subseteq \mathfrak{sl}_n$, so by the argument of Lemma 13.7.2(4) its trace on $\mathfrak{gl}_n$ equals its trace on $\mathfrak{sl}_n$:

$$\kappa_{\mathfrak{sl}_n}(x, y) = 2n \operatorname{tr}(xy).$$

This form is nondegenerate for $n \geq 2$: if $x \in \mathfrak{sl}_n$ and $\operatorname{tr}(xy) = 0$ for all $y \in \mathfrak{sl}_n$, then $y = E_{ji}$ $(i \neq j)$ gives $x_{ij} = 0$, and $y = E_{ii} - E_{jj}$ gives $x_{ii} = x_{jj}$; so $x = cI$ with $nc = \operatorname{tr} x = 0$, and $x = 0$. Hence $\mathfrak{sl}_n(k)$ is semisimple. For $n = 2$, in the basis e, h, f of Section 13.6, $\kappa(e, f) = 4$, $\kappa(h, h) = 8$, and all other pairings of basis vectors vanish.

2. *A solvable example.* For the Lie algebra with basis x, y and $[x, y] = y$ (Example 13.5.3(3)), the matrices of $\operatorname{ad} x$ and $\operatorname{ad} y$ in the basis (x, y) are $\left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 & 0 \\ -1 & 0 \end{smallmatrix}\right)$, so $\kappa(x, x) = 1$ and $\kappa(x, y) = \kappa(y, y) = 0$. The form vanishes on $[\mathfrak{g}, \mathfrak{g}] \times \mathfrak{g} = ky \times \mathfrak{g}$, as Corollary 13.7.7 predicts, but it is not zero: the Killing form of a solvable Lie algebra need not vanish, in contrast with the nilpotent case (Exercise 13.12.8).

Theorem 13.7.10. *Let $\mathfrak{g}$ be semisimple. There are simple ideals $\mathfrak{g}_1, \ldots, \mathfrak{g}_t$ with $\mathfrak{g} = \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_t$, and $[\mathfrak{g}_i, \mathfrak{g}_j] = 0$ for $i \neq j$. Every simple ideal of $\mathfrak{g}$ is one of the $\mathfrak{g}_i$, and every ideal is a sum of some of them. In particular $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}$, and ideals and quotients of $\mathfrak{g}$ are semisimple.*

Proof. Let $\mathfrak{a}$ be an ideal. Then $\mathfrak{a}^\perp$, the orthogonal for κ, is an ideal (Lemma 13.7.2(3)), and so is $\mathfrak{a} \cap \mathfrak{a}^\perp$, on which the Killing form of $\mathfrak{g}$ vanishes. By Lemma 13.7.2(4) and Corollary 13.7.7, $\mathfrak{a} \cap \mathfrak{a}^\perp$ is solvable, hence 0. Since κ is nondegenerate (Theorem 13.7.8), $\mathfrak{a}^\perp$ is the kernel of the map $\mathfrak{g} \to \mathfrak{a}^*$, $x \mapsto \kappa(x, -)|_{\mathfrak{a}}$, so $\dim \mathfrak{a}^\perp \geq \dim \mathfrak{g} - \dim \mathfrak{a}$. Hence $\mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^\perp$, and $[\mathfrak{a}, \mathfrak{a}^\perp] \subseteq \mathfrak{a} \cap \mathfrak{a}^\perp = 0$. Consequently an ideal $\mathfrak{b}$ of the Lie algebra $\mathfrak{a}$ is an ideal of $\mathfrak{g}$, since $[\mathfrak{g}, \mathfrak{b}] = [\mathfrak{a}, \mathfrak{b}] + [\mathfrak{a}^\perp, \mathfrak{b}] = [\mathfrak{a}, \mathfrak{b}] \subseteq \mathfrak{b}$. In particular a solvable ideal of $\mathfrak{a}$ is a solvable ideal of $\mathfrak{g}$, hence 0: $\mathfrak{a}$ is semisimple, and so is $\mathfrak{g}/\mathfrak{a} \cong \mathfrak{a}^\perp$.

Existence of the decomposition, by induction on $\dim \mathfrak{g}$: if $\mathfrak{g} \neq 0$, let $\mathfrak{a}$ be a nonzero ideal of minimal dimension. Its ideals are ideals of $\mathfrak{g}$, so they are 0 and $\mathfrak{a}$; and $\mathfrak{a}$ is not abelian, being semisimple and nonzero. So $\mathfrak{a}$ is simple, and $\mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^\perp$ with $\mathfrak{a}^\perp$ semisimple, to which the induction hypothesis applies; the simple ideals of $\mathfrak{a}^\perp$ are ideals of $\mathfrak{g}$.

Let $\mathfrak{b}$ be a simple ideal of $\mathfrak{g}$. Then $[\mathfrak{g}, \mathfrak{b}] = \mathfrak{b}$, since it is a nonzero ideal of $\mathfrak{b}$ (nonzero because the centre of $\mathfrak{g}$ is 0). So $\mathfrak{b} = \sum_i [\mathfrak{g}_i, \mathfrak{b}]$, and each $[\mathfrak{g}_i, \mathfrak{b}] \subseteq \mathfrak{g}_i \cap \mathfrak{b}$ is an ideal of $\mathfrak{g}$ contained in $\mathfrak{b}$, hence 0 or $\mathfrak{b}$. As the $\mathfrak{g}_i$ are independent, exactly one is $\mathfrak{b}$, and then $\mathfrak{b} \subseteq \mathfrak{g}_i$ is a nonzero ideal of the simple $\mathfrak{g}_i$, so $\mathfrak{b} = \mathfrak{g}_i$. An arbitrary ideal $\mathfrak{a}$ is semisimple, so by the existence part it is a sum of simple ideals of $\mathfrak{a}$, which are simple ideals of $\mathfrak{g}$, hence some of the $\mathfrak{g}_i$. Finally $[\mathfrak{g}, \mathfrak{g}] = \sum_i [\mathfrak{g}_i, \mathfrak{g}_i] = \sum_i \mathfrak{g}_i$ by Lemma 13.7.2(2). □

A *derivation* of a Lie algebra $\mathfrak{g}$ is a linear map $\delta \colon \mathfrak{g} \to \mathfrak{g}$ with $\delta[x, y] = [\delta x, y] + [x, \delta y]$. The derivations form a Lie subalgebra $\operatorname{Der} \mathfrak{g} \subseteq \mathfrak{gl}(\mathfrak{g})$, and by the Jacobi identity every $\operatorname{ad} x$ is a derivation, called *inner*. For $\delta \in \operatorname{Der} \mathfrak{g}$ and $x \in \mathfrak{g}$,

$$[\delta, \operatorname{ad} x] = \operatorname{ad}(\delta x),$$

since $[\delta, \operatorname{ad} x](y) = \delta[x, y] - [x, \delta y] = [\delta x, y]$; so $\operatorname{ad} \mathfrak{g}$ is an ideal of $\operatorname{Der} \mathfrak{g}$.

Theorem 13.7.11. *If $\mathfrak{g}$ is semisimple, every derivation of $\mathfrak{g}$ is inner, and $\operatorname{ad} \colon \mathfrak{g} \to \operatorname{Der} \mathfrak{g}$ is an isomorphism of Lie algebras.*

Proof. ad is injective, as the centre is 0. Let $D = \operatorname{Der} \mathfrak{g}$ and $I = \operatorname{ad} \mathfrak{g} \cong \mathfrak{g}$, an ideal of D. The Killing form of I is the restriction of κ_D (Lemma 13.7.2(4)), and it is nondegenerate since $I \cong \mathfrak{g}$ is semisimple; so $I \cap I^\perp = 0$, where $I^\perp$ is the orthogonal of I for κ_D, an ideal of D. Then $[I, I^\perp] \subseteq I \cap I^\perp = 0$, and for $\delta \in I^\perp$ and $x \in \mathfrak{g}$, $\operatorname{ad}(\delta x) = [\delta, \operatorname{ad} x] = 0$, so $\delta x = 0$: $I^\perp = 0$. As in the proof of Theorem 13.7.10, $\dim I^\perp \geq \dim D - \dim I$, so $D = I$. □

Proposition 13.7.12 (Abstract Jordan decomposition)**.** *Let k be algebraically closed and $\mathfrak{g}$ semisimple. Every $x \in \mathfrak{g}$ can be written uniquely as $x = x_s + x_n$ with $\operatorname{ad} x_s$ diagonalisable, $\operatorname{ad} x_n$ nilpotent and $[x_s, x_n] = 0$. Moreover $\operatorname{ad} x_s$ and $\operatorname{ad} x_n$ are the semisimple and nilpotent parts of $\operatorname{ad} x$, and every $y \in \mathfrak{g}$ commuting with x commutes with x_s and x_n.*

Proof. Let $\operatorname{ad} x = \sigma + \nu$ be the Jordan–Chevalley decomposition in $\operatorname{End}(\mathfrak{g})$. For $a \in k$ let $\mathfrak{g}_a = \ker(\operatorname{ad} x - a)^d$, $d = \dim \mathfrak{g}$; then $\mathfrak{g} = \bigoplus_a \mathfrak{g}_a$ and $\sigma = a$ on $\mathfrak{g}_a$ (Step 1 of the proof of Theorem 11.8.11). Since $\operatorname{ad} x$ is a derivation, $(\operatorname{ad} x - a - b)[y, z] = [(\operatorname{ad} x - a)y, z] + [y, (\operatorname{ad} x - b)z]$, and by induction

$$(\operatorname{ad} x - a - b)^m [y, z] = \sum_{i=0}^{m} \binom{m}{i} \big[(\operatorname{ad} x - a)^i y, (\operatorname{ad} x - b)^{m-i} z\big].$$

For $y \in \mathfrak{g}_a$, $z \in \mathfrak{g}_b$ and $m = 2d$ every term vanishes, so $[y, z] \in \mathfrak{g}_{a+b}$, and $\sigma[y, z] = (a+b)[y, z] = [\sigma y, z] + [y, \sigma z]$. By bilinearity σ is a derivation, so $\sigma = \operatorname{ad} x_s$ for a unique x_s (Theorem 13.7.11). Put $x_n = x - x_s$; then $\operatorname{ad} x_n = \nu$ is nilpotent, and $\operatorname{ad}[x_s, x_n] = [\sigma, \nu] = 0$ gives $[x_s, x_n] = 0$, as ad is injective. If $x = s' + n'$ is another such decomposition, then $\operatorname{ad} x = \operatorname{ad} s' + \operatorname{ad} n'$ is a Jordan–Chevalley decomposition, so $\operatorname{ad} s' = \sigma$ and $s' = x_s$. Finally, if $[x, y] = 0$, then $\operatorname{ad} y$ commutes with $\operatorname{ad} x$, hence with the polynomial σ in $\operatorname{ad} x$; so $\operatorname{ad}[y, x_s] = [\operatorname{ad} y, \sigma] = 0$ and $[y, x_s] = 0$. □

We call x *semisimple* if $x = x_s$, that is, if $\operatorname{ad} x$ is diagonalisable, and *nilpotent* if $x = x_n$. For $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ this agrees with the usual Jordan decomposition of the matrix x (Corollary 13.8.4 below), but that requires Weyl's theorem.

To recognise semisimple Lie algebras of matrices, the following criterion is often quicker than computing the Killing form. A Lie algebra is *reductive* if it is the direct sum $\mathfrak{z}(\mathfrak{g}) \oplus \mathfrak{s}$ of its centre and a semisimple ideal $\mathfrak{s}$.

Proposition 13.7.13. *Let $k = \mathbb{R}$ or $\mathbb{C}$, and let $\mathfrak{g}$ be a Lie algebra over k with an inner product (Hermitian if $k = \mathbb{C}$) such that the adjoint of every $\operatorname{ad} x$ is of the form $\operatorname{ad} x'$ for some $x' \in \mathfrak{g}$. Then the orthogonal complement of an ideal is an ideal, $\mathfrak{g}$ is the orthogonal direct sum of its centre and of simple ideals, and $\mathfrak{g} = \mathfrak{z}(\mathfrak{g}) \oplus [\mathfrak{g}, \mathfrak{g}]$ with $[\mathfrak{g}, \mathfrak{g}]$ semisimple. In particular $\mathfrak{g}$ is reductive, and it is semisimple if its centre is 0.*

Proof. Let $\mathfrak{a}$ be an ideal, $z \in \mathfrak{a}^\perp$, $x \in \mathfrak{g}$ and $a \in \mathfrak{a}$. With $(\operatorname{ad} x)^* = \operatorname{ad} x'$, $\langle [x, z], a\rangle = \langle z, [x', a]\rangle = 0$, since $[x', a] \in \mathfrak{a}$. So $\mathfrak{a}^\perp$ is an ideal, and $\mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^\perp$.

Every ideal $\mathfrak{b}$ is an orthogonal direct sum of minimal nonzero ideals of $\mathfrak{g}$, by induction on $\dim \mathfrak{b}$: if $\mathfrak{b} \neq 0$, it contains a minimal nonzero ideal $\mathfrak{a}$ of $\mathfrak{g}$, and $\mathfrak{b} = \mathfrak{a} \oplus (\mathfrak{b} \cap \mathfrak{a}^\perp)$, because for $y \in \mathfrak{b}$ the component of y in $\mathfrak{a}^\perp$ is y minus an element of $\mathfrak{a} \subseteq \mathfrak{b}$. So $\mathfrak{g} = \mathfrak{a}_1 \oplus \cdots \oplus \mathfrak{a}_m$ with minimal nonzero ideals $\mathfrak{a}_i$, and $[\mathfrak{a}_i, \mathfrak{a}_j] \subseteq \mathfrak{a}_i \cap \mathfrak{a}_j = 0$ for $i \neq j$. Hence an ideal $\mathfrak{c}$ of the Lie algebra $\mathfrak{a}_i$ is an ideal of $\mathfrak{g}$, as $[\mathfrak{g}, \mathfrak{c}] = [\mathfrak{a}_i, \mathfrak{c}]$, and by minimality $\mathfrak{a}_i$ has no ideals but 0 and itself. So each $\mathfrak{a}_i$ is either simple or abelian, and in the abelian case every subspace is an ideal, so $\dim \mathfrak{a}_i = 1$.

An element $\sum_i x_i$, $x_i \in \mathfrak{a}_i$, is central if and only if each x_i is central in $\mathfrak{a}_i$; the centre of a simple Lie algebra is 0, so $\mathfrak{z}(\mathfrak{g})$ is the sum of the abelian $\mathfrak{a}_i$. And $[\mathfrak{g}, \mathfrak{g}] = \sum_i [\mathfrak{a}_i, \mathfrak{a}_i]$ is the sum $\mathfrak{s}$ of the simple $\mathfrak{a}_i$ (Lemma 13.7.2(2)). It remains to see that $\mathfrak{s}$ is semisimple. If $\mathfrak{r}$ is an abelian ideal of $\mathfrak{s}$ and $\mathfrak{a}_i$ is one of its simple summands, then $\mathfrak{a}_i \cap \mathfrak{r}$ is an abelian ideal of $\mathfrak{a}_i$, hence 0, and so $[\mathfrak{a}_i, \mathfrak{r}] \subseteq \mathfrak{a}_i \cap \mathfrak{r} = 0$. Thus $\mathfrak{r}$ is central in $\mathfrak{s}$, whose centre is 0; so $\mathfrak{r} = 0$, and $\mathfrak{s}$ is semisimple by Lemma 13.7.2(2). □

The hypothesis holds for every complex Lie subalgebra $\mathfrak{g} \subseteq \mathfrak{gl}_n(\mathbb{C})$ that is closed under $x \mapsto x^* = \bar{x}^T$, with the Hermitian inner product $\langle x, y\rangle = \operatorname{tr}(xy^*) = \sum_{i,j} x_{ij}\bar{y}_{ij}$: then $(\operatorname{ad} x)^* = \operatorname{ad}(x^*)$, because

$$\langle [x, y], z\rangle = \operatorname{tr}(xyz^* - yxz^*) = \operatorname{tr}\big(y(z^*x - xz^*)\big) = \operatorname{tr}\big(y[x^*, z]^*\big) = \langle y, [x^*, z]\rangle.$$

It also holds for the Lie algebra of a compact Lie group, with an invariant inner product (Chapter 34).

Example 13.7.14. *The classical Lie algebras.* Let $J = \left(\begin{smallmatrix} 0 & I_n \\ -I_n & 0 \end{smallmatrix}\right)$ and let $\mathfrak{sp}_{2n}(k) = \{x \in \mathfrak{gl}_{2n}(k) : x^TJ + Jx = 0\}$, the Lie algebra of the bilinear form v^TJw in the sense of Example 13.4.2(3). Writing x in blocks of size n, $x^TJ + Jx = 0$ says exactly that

$$x = \begin{pmatrix} A & B \\ C & -A^T \end{pmatrix}, \qquad B = B^T, \quad C = C^T,$$

so $\dim \mathfrak{sp}_{2n} = n^2 + n(n+1) = n(2n+1)$. The Lie algebras $\mathfrak{sl}_n(\mathbb{C})$ ($n \geq 2$), $\mathfrak{so}_n(\mathbb{C})$ ($n \geq 3$) and $\mathfrak{sp}_{2n}(\mathbb{C})$ ($n \geq 1$) are semisimple, and $\mathfrak{gl}_n(\mathbb{C}) = \mathbb{C}I \oplus \mathfrak{sl}_n(\mathbb{C})$ is reductive. All four are closed under $x \mapsto x^*$: for $\mathfrak{so}_n$ the conjugate of a skew-symmetric matrix is skew-symmetric, and for $\mathfrak{sp}_{2n}$, conjugating $x^TJ + Jx = 0$ and multiplying by $J^{-1} = -J$ on both sides gives $\bar{x}J + J\bar{x}^T = 0$, which is the condition for x^*. By Proposition 13.7.13 it suffices to compute the centres.

1. $\mathfrak{sl}_n$: if x commutes with E_{ij}, $i \neq j$, comparing the entries in row i of $E_{ij}x = xE_{ij}$ gives $x_{jl} = 0$ for $l \neq j$ and $x_{jj} = x_{ii}$. So a central x is a scalar matrix cI with $nc = \operatorname{tr} x = 0$, and $x = 0$. The centre of $\mathfrak{gl}_n$ is $\mathbb{C}I$ by the same computation.

2. $\mathfrak{so}_n$, $n \geq 3$: a central x commutes with $F_{ij} = E_{ij} - E_{ji}$, so it preserves its image $\operatorname{span}(e_i, e_j)$. For distinct i, j, l it preserves $\operatorname{span}(e_i, e_j) \cap \operatorname{span}(e_i, e_l) = \mathbb{C}e_i$; so x is diagonal, and a diagonal skew-symmetric matrix is 0. (For $n = 2$, $\mathfrak{so}_2$ is one-dimensional, hence abelian.)

3. $\mathfrak{sp}_{2n}$: write a central x in blocks P, Q, R, S. Commuting with all $\operatorname{diag}(A, -A^T) \in \mathfrak{sp}_{2n}$ means $PA = AP$, $QA^T = -AQ$, $RA = -A^T R$ and $SA^T = A^T S$ for all $A \in \mathfrak{gl}_n$; so P and S are scalar, and $A = I$ gives $Q = R = 0$. Then $x = p\operatorname{diag}(I, -I)$, and commuting with $\left(\begin{smallmatrix} 0 & I \\ 0 & 0 \end{smallmatrix}\right) \in \mathfrak{sp}_{2n}$ gives $2p = 0$.

The real Lie algebras $\mathfrak{su}(n)$ ($n \geq 2$) and $\mathfrak{so}(n)$ ($n \geq 3$) are semisimple for the same reason, with the real inner product $\operatorname{Re}\operatorname{tr}(xy^*)$ and $x^* = -x$. These are the Lie algebras $\mathfrak{sl}_n$ ($n \geq 2$), $\mathfrak{so}_{2n+1}$ ($n \geq 1$), $\mathfrak{sp}_{2n}$ ($n \geq 1$) and $\mathfrak{so}_{2n}$ ($n \geq 2$) of the four infinite families in the classification (Section 13.10).

13.8 Weyl's theorem

For $\mathfrak{sl}_2$, complete reducibility was proved with the Casimir operator $C = ef + fe + \frac{1}{2}h^2$, which commutes with the action and separates the irreducible representations (Theorem 13.6.3). The same element exists for every semisimple Lie algebra; it is built from a nondegenerate invariant form, and it gives complete reducibility in general. In this section $\mathfrak{g}$ is semisimple and k has characteristic 0.

Lemma 13.8.1 (Casimir element)**.** *Let $\varphi\colon \mathfrak{g} \to \mathfrak{gl}(V)$ be a faithful (injective) representation. Then the trace form $\beta = \beta_\varphi$ is nondegenerate. Let $x_1, \dots, x_n$ be a basis of $\mathfrak{g}$ and $y_1, \dots, y_n$ the dual basis, $\beta(x_i, y_j) = \delta_{ij}$, and put*

$$c_\varphi = \sum_{i=1}^{n} \varphi(x_i)\varphi(y_i) \in \operatorname{End}(V).$$

Then c_φ commutes with $\varphi(x)$ for all $x \in \mathfrak{g}$, and $\operatorname{tr} c_\varphi = \dim \mathfrak{g}$.

Proof. The radical S of β is an ideal (Lemma 13.7.2(3)), and $\operatorname{tr}(\varphi(x)\varphi(y)) = 0$ for $x, y \in S$; by Cartan's criterion (Theorem 13.7.6) $\varphi(S) \cong S$ is solvable, so $S = 0$. For $x \in \mathfrak{g}$ write $[x, x_i] = \sum_j a_{ij} x_j$ and $[x, y_i] = \sum_j b_{ij} y_j$. By invariance, $a_{il} = \beta([x, x_i], y_l) = -\beta([x_i, x], y_l) = -\beta(x_i, [x, y_l]) = -b_{li}$. Using $[X, YZ] = [X, Y]Z + Y[X, Z]$ in $\operatorname{End}(V)$,

$$[\varphi(x), c_\varphi] = \sum_i \big([\varphi(x), \varphi(x_i)]\varphi(y_i) + \varphi(x_i)[\varphi(x), \varphi(y_i)]\big) = \sum_{i,j} a_{ij}\varphi(x_j)\varphi(y_i) + \sum_{i,j} b_{ij}\varphi(x_i)\varphi(y_j),$$

and renaming the indices in the second sum, it becomes $\sum_{i,j} b_{ji}\varphi(x_j)\varphi(y_i) = -\sum_{i,j} a_{ij}\varphi(x_j)\varphi(y_i)$. Finally $\operatorname{tr} c_\varphi = \sum_i \beta(x_i, y_i) = n$. □

If φ is not faithful, its kernel is an ideal, so $\mathfrak{g} = \ker\varphi \oplus \mathfrak{g}'$ where $\mathfrak{g}'$ is the sum of the other simple ideals (Theorem 13.7.10); $\varphi|_{\mathfrak{g}'}$ is faithful with the same image, and we define $c_\varphi = c_{\varphi|\mathfrak{g}'}$. It commutes with $\varphi(\mathfrak{g})$, and its trace is $\dim \varphi(\mathfrak{g})$. For $\mathfrak{sl}_2$ acting on k^2 the trace form is $\operatorname{tr}(xy)$, the dual basis of e, f, h is $f, e, \frac{1}{2}h$, and $c_\varphi = ef + fe + \frac{1}{2}h^2$ is the Casimir operator of Theorem 13.6.3.

Theorem 13.8.2 (Weyl)**.** *Every finite-dimensional representation of a semisimple Lie algebra over a field of characteristic 0 is completely reducible.*

Proof. It suffices to show that every subrepresentation W of a representation V has a complementary subrepresentation; complete reducibility then follows by induction on $\dim V$. First note that $\mathfrak{g}$ acts by 0 on every one-dimensional representation, since $\mathfrak{gl}_1$ is abelian and $\mathfrak{g} = [\mathfrak{g}, \mathfrak{g}]$.

Step 1: W of codimension 1. We argue by induction on $\dim V$. By the remark just made, $\mathfrak{g}V \subseteq W$. If $\varphi = 0$, any complement will do. Suppose first that W is irreducible, and let $c = c_\varphi$.

It maps V into W, being a sum of products of elements of $\varphi(\mathfrak{g})$, so $\operatorname{tr}(c|_W) = \operatorname{tr} c = \dim \varphi(\mathfrak{g}) \neq 0$ (Lemma 13.7.2(4)). Since c commutes with $\mathfrak{g}$, $\ker(c|_W)$ is a subrepresentation of W, not equal to W, hence 0. So $\ker c \cap W = 0$, while $\dim \ker c \geq \dim V - \dim W = 1$ because $c(V) \subseteq W$; hence $V = W \oplus \ker c$, and $\ker c$ is a subrepresentation. If W is not irreducible, let $0 \neq W' \subsetneq W$ be a subrepresentation. By induction, applied to $W/W' \subseteq V/W'$, there is a subrepresentation $\widetilde{W} \supseteq W'$ with $V/W' = W/W' \oplus \widetilde{W}/W'$ and $\dim \widetilde{W}/W' = 1$. By induction again, applied to $W' \subseteq \widetilde{W}$ (of codimension 1, and $\dim \widetilde{W} < \dim V$), $\widetilde{W} = W' \oplus X$ with X a subrepresentation of dimension 1. Then $X \cap W \subseteq \widetilde{W} \cap W = W'$, so $X \cap W = X \cap W' = 0$, and $V = W \oplus X$.

Step 2: general $W \neq 0$. The space $\operatorname{Hom}_k(V, W)$ is a representation with $(x \cdot f)(v) = xf(v) - f(xv)$ (it is $V^* \otimes W$, Definition 13.4.3). Let $\mathcal{V}$ be the subspace of maps f whose restriction to W is a scalar multiple $\lambda_f \mathrm{id}_W$, and $\mathcal{W} \subseteq \mathcal{V}$ those with $f|_W = 0$. For $f \in \mathcal{V}$ and $w \in W$, $(x \cdot f)(w) = \lambda_f xw - \lambda_f xw = 0$, so $\mathfrak{g}\mathcal{V} \subseteq \mathcal{W}$; in particular both are subrepresentations, and $\mathcal{W}$ has codimension 1 in $\mathcal{V}$, because $f \mapsto \lambda_f$ is onto (extend id_W by a linear projection). By Step 1, $\mathcal{V} = \mathcal{W} \oplus kf$ with kf a subrepresentation, on which $\mathfrak{g}$ acts by 0. We may take $\lambda_f = 1$. Then $x \cdot f = 0$ says $xf(v) = f(xv)$: $f : V \to W$ is a homomorphism of representations which is the identity on W, and $\ker f$ is a subrepresentation complementary to W. □

Counterexample 13.8.3. Semisimplicity is needed. The one-dimensional Lie algebra k acts on k^2 by $t \mapsto \left(\begin{smallmatrix} 0 & t \\ 0 & 0 \end{smallmatrix}\right)$; the line ke_1 is a subrepresentation, and a complementary one would be a second line killed by the nilpotent matrix, whose kernel is ke_1. The same happens for the adjoint representation of the solvable Lie algebra with $[x, y] = y$: the ideal ky has no complementary ideal, as a complement would be a line $k(x + cy)$ with $[y, x + cy] = -y$ in it.

Corollary 13.8.4 (Preservation of the Jordan decomposition)**.** *Let k be algebraically closed.*

1. *If $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ is a semisimple Lie subalgebra and $x \in \mathfrak{g}$, the semisimple and nilpotent parts s, n of the endomorphism x lie in $\mathfrak{g}$, and they are the parts x_s, x_n of the abstract Jordan decomposition.*

2. *If $\varphi : \mathfrak{g} \to \mathfrak{gl}(V)$ is a representation of a semisimple Lie algebra, then $\varphi(x_s)$ and $\varphi(x_n)$ are the semisimple and nilpotent parts of $\varphi(x)$. In particular a semisimple element acts diagonalisably in every finite-dimensional representation.*

Proof. (1) By Lemma 13.7.4, $\operatorname{ad} s$ and $\operatorname{ad} n$ are polynomials without constant term in $\operatorname{ad} x$, which maps $\mathfrak{g}$ into itself; so s and n lie in the normaliser $N = \{y \in \mathfrak{gl}(V) : [y, \mathfrak{g}] \subseteq \mathfrak{g}\}$, a Lie subalgebra. For each subrepresentation $W \subseteq V$ let $L_W = \{y \in \mathfrak{gl}(V) : y(W) \subseteq W,\ \operatorname{tr}(y|_W) = 0\}$, also a Lie subalgebra. It contains $\mathfrak{g} = [\mathfrak{g}, \mathfrak{g}]$, as the restrictions of commutators are commutators, and it contains s and n: these are polynomials in x, so they preserve W, $n|_W$ is nilpotent, so of trace 0, and $s|_W = x|_W - n|_W$. Let $\mathfrak{g}' = N \cap \bigcap_W L_W$; it contains $\mathfrak{g}$, s and n, and $\mathfrak{g}$ is an ideal of $\mathfrak{g}'$. By Weyl's theorem, applied to the representation ad of $\mathfrak{g}$ on $\mathfrak{g}'$, $\mathfrak{g}' = \mathfrak{g} \oplus M$ with $[\mathfrak{g}, M] \subseteq M$; also $[\mathfrak{g}, M] \subseteq \mathfrak{g}$, so $[\mathfrak{g}, M] = 0$. Let $y \in M$ and let $W \subseteq V$ be an irreducible subrepresentation. Then $y|_W$ commutes with $\mathfrak{g}$, so it is a scalar by Schur's lemma (Lemma 13.2.3, whose proof applies to Lie algebras), and it has trace 0, so $y|_W = 0$. By Weyl's theorem V is a sum of irreducible subrepresentations, so $y = 0$. Hence $\mathfrak{g}' = \mathfrak{g}$ contains s and n. Now $\operatorname{ad}_{\mathfrak{g}} s$ is diagonalisable, as the restriction of the diagonalisable $\operatorname{ad} s$ to an invariant subspace, $\operatorname{ad}_{\mathfrak{g}} n$ is nilpotent, and $[s, n] = 0$; by uniqueness in Proposition 13.7.12, $s = x_s$ and $n = x_n$.

(2) The image $\varphi(\mathfrak{g}) \cong \mathfrak{g}/\ker\varphi$ is semisimple (Theorem 13.7.10). $\mathfrak{g}$ has a basis of eigenvectors of $\operatorname{ad} x_s$, and φ maps it onto a spanning set of $\varphi(\mathfrak{g})$ consisting of eigenvectors of $\operatorname{ad}\varphi(x_s)$; so $\operatorname{ad}\varphi(x_s)$ is diagonalisable on $\varphi(\mathfrak{g})$. Similarly $(\operatorname{ad}\varphi(x_n))^N \varphi(y) = \varphi((\operatorname{ad} x_n)^N y) = 0$ for large N, and $[\varphi(x_s), \varphi(x_n)] = 0$. By uniqueness, $\varphi(x) = \varphi(x_s) + \varphi(x_n)$ is the abstract Jordan decomposition in $\varphi(\mathfrak{g})$, and by (1) it is the Jordan decomposition of the endomorphism $\varphi(x)$. □

13.9 The root space decomposition

In $\mathfrak{sl}_n$ the diagonal matrices $\mathfrak{h}$ act on $\mathfrak{sl}_n$ by ad diagonalisably: $[h, E_{ij}] = (h_i - h_j)E_{ij}$ for $h = \operatorname{diag}(h_1, \dots, h_n)$. So $\mathfrak{sl}_n$ is the sum of $\mathfrak{h}$ and of the lines $\mathbb{C}E_{ij}$, on which $\mathfrak{h}$ acts through the linear forms $h \mapsto h_i - h_j$, the *roots*. This section shows that every semisimple Lie algebra has such a decomposition, and that the roots satisfy strong integrality conditions, all coming from the representation theory of $\mathfrak{sl}_2$. In this section $k = \mathbb{C}$ (the proofs work over any algebraically closed field of characteristic 0), and $\mathfrak{g}$ is semisimple, with Killing form κ.

Definition 13.9.1. A subalgebra $\mathfrak{t} \subseteq \mathfrak{g}$ is *toral* if all its elements are semisimple, that is, every $\operatorname{ad} x$, $x \in \mathfrak{t}$, is diagonalisable. A *Cartan subalgebra* of $\mathfrak{g}$ is a maximal toral subalgebra (one not contained in a larger toral subalgebra).

For semisimple Lie algebras over $\mathbb{C}$ this agrees with the general definition of a Cartan subalgebra as a nilpotent subalgebra equal to its own normaliser [Hum72, Section 15].

Lemma 13.9.2. *Toral subalgebras are abelian, and if $\mathfrak{g} \neq 0$ it has nonzero toral subalgebras. Hence Cartan subalgebras exist, and they are abelian and nonzero.*

Proof. Let $\mathfrak{t}$ be toral and $x \in \mathfrak{t}$. Since $\operatorname{ad}_{\mathfrak{t}} x$ is the restriction of the diagonalisable $\operatorname{ad} x$ to an invariant subspace, it is diagonalisable, and it suffices to show that it has no nonzero eigenvalue. Suppose $[x, y] = ay$ with $y \in \mathfrak{t}$ and $a \neq 0$. Then $\operatorname{ad}_{\mathfrak{t}} y(x) = -ay$ is a nonzero eigenvector of $\operatorname{ad}_{\mathfrak{t}} y$ with eigenvalue 0. But $\operatorname{ad}_{\mathfrak{t}} y$ is diagonalisable: writing $x = \sum_i v_i$ with $[y, v_i] = \lambda_i v_i$, the vector $[y, x] = \sum_{\lambda_i \neq 0} \lambda_i v_i$ lies in the sum of the eigenspaces with nonzero eigenvalues, which meets the kernel only in 0; contradiction.

If every $x \in \mathfrak{g}$ satisfied $x_s = 0$, every $\operatorname{ad} x$ would be nilpotent, and $\mathfrak{g}$ would be nilpotent by Engel's theorem (Corollary 13.5.6), hence solvable, hence 0. So some x_s is nonzero, and $\mathbb{C}x_s$ is toral. A toral subalgebra of maximal dimension is maximal. □

Fix a Cartan subalgebra $\mathfrak{h}$. Its elements commute, so the operators $\operatorname{ad} h$, $h \in \mathfrak{h}$, are commuting diagonalisable endomorphisms of $\mathfrak{g}$, and they are simultaneously diagonalisable: apply Theorem 11.7.6 to $\operatorname{ad} h_1$, then to the restrictions of $\operatorname{ad} h_2$ to its eigenspaces, and so on, for a basis $h_1, \dots, h_l$ of $\mathfrak{h}$. A common eigenvector x satisfies $[h, x] = \alpha(h)x$ for a linear form $\alpha \in \mathfrak{h}^*$. Hence

$$\mathfrak{g} = \bigoplus_{\alpha \in \mathfrak{h}^*} \mathfrak{g}_\alpha, \qquad \mathfrak{g}_\alpha = \{x \in \mathfrak{g} : [h, x] = \alpha(h)x \text{ for all } h \in \mathfrak{h}\}.$$

Here $\mathfrak{g}_0 = C_{\mathfrak{g}}(\mathfrak{h})$ is the centraliser of $\mathfrak{h}$, which contains $\mathfrak{h}$. The *roots* of $\mathfrak{g}$ with respect to $\mathfrak{h}$ are the nonzero α with $\mathfrak{g}_\alpha \neq 0$; they form a finite set $\Phi \subseteq \mathfrak{h}^*$, and $\mathfrak{g}_\alpha$ is the *root space* of α.

Proposition 13.9.3. *For $\alpha, \beta \in \mathfrak{h}^*$:*

1. $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] \subseteq \mathfrak{g}_{\alpha+\beta}$;
2. *if $\alpha \neq 0$ and $x \in \mathfrak{g}_\alpha$, then $\operatorname{ad} x$ is nilpotent;*
3. *if $\alpha + \beta \neq 0$, then $\kappa(\mathfrak{g}_\alpha, \mathfrak{g}_\beta) = 0$;*
4. *the restriction of κ to $\mathfrak{g}_0$ is nondegenerate.*

Proof. (1) For $x \in \mathfrak{g}_\alpha$, $y \in \mathfrak{g}_\beta$, the Jacobi identity gives $[h, [x, y]] = [[h, x], y] + [x, [h, y]] = (\alpha(h) + \beta(h))[x, y]$. (2) By (1), $\operatorname{ad} x$ maps $\mathfrak{g}_\gamma$ into $\mathfrak{g}_{\gamma+\alpha}$, and only finitely many $\mathfrak{g}_\gamma$ are nonzero. (3) Choose h with $\alpha(h) + \beta(h) \neq 0$; by invariance, for $x \in \mathfrak{g}_\alpha$ and $y \in \mathfrak{g}_\beta$, $\alpha(h)\kappa(x, y) = \kappa([h, x], y) = -\kappa([x, h], y) = -\kappa(x, [h, y]) = -\beta(h)\kappa(x, y)$, so $\kappa(x, y) = 0$. (4) By (3), $\mathfrak{g}_0$ is orthogonal to all $\mathfrak{g}_\alpha$ with $\alpha \neq 0$; so an element of $\mathfrak{g}_0$ orthogonal to $\mathfrak{g}_0$ is orthogonal to $\mathfrak{g}$, hence zero (Theorem 13.7.8). □

Theorem 13.9.4. $C_\mathfrak{g}(\mathfrak{h}) = \mathfrak{h}$. *Hence* $\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha\in\Phi} \mathfrak{g}_\alpha$, *and the restriction of* κ *to* $\mathfrak{h}$ *is nondegenerate.*

Proof. Write $C = C_\mathfrak{g}(\mathfrak{h})$, a subalgebra by the Jacobi identity.

Step 1: C contains the semisimple and nilpotent parts of its elements. For $x \in C$, $\operatorname{ad} x$ maps $\mathfrak{h}$ to 0, and $\operatorname{ad} x_s$, $\operatorname{ad} x_n$ are polynomials without constant term in $\operatorname{ad} x$ (Proposition 13.7.12 and Lemma 13.7.4(1)); so they also kill $\mathfrak{h}$.

Step 2: the semisimple elements of C lie in $\mathfrak{h}$. If $s \in C$ is semisimple, $\mathfrak{h} + \mathbb{C}s$ is an abelian subalgebra, and its elements $h + cs$ have $\operatorname{ad}(h + cs) = \operatorname{ad} h + c \operatorname{ad} s$, a sum of commuting diagonalisable endomorphisms, which is diagonalisable (Theorem 11.7.6). So $\mathfrak{h} + \mathbb{C}s$ is toral, and $s \in \mathfrak{h}$ by maximality.

Step 3: $\kappa|_\mathfrak{h}$ is nondegenerate. Let $h \in \mathfrak{h}$ with $\kappa(h, \mathfrak{h}) = 0$, and $x \in C$. Then $x_s \in \mathfrak{h}$ by Steps 1 and 2, so $\kappa(h, x_s) = 0$. And $x_n \in C$, so $\operatorname{ad} x_n$ is nilpotent and commutes with $\operatorname{ad} h$; then $\operatorname{ad} h \operatorname{ad} x_n$ is nilpotent and $\kappa(h, x_n) = 0$. So $\kappa(h, C) = 0$, and $h = 0$ by Proposition 13.9.3(4).

Step 4: C is nilpotent. For $x \in C$, $\operatorname{ad}_C x_s = 0$ since $x_s \in \mathfrak{h}$, and $\operatorname{ad}_C x_n$ is nilpotent; so every $\operatorname{ad}_C x = \operatorname{ad}_C x_n$ is nilpotent, and C is nilpotent by Engel's theorem.

Step 5: $\mathfrak{h} \cap [C, C] = 0$. By invariance $\kappa(\mathfrak{h}, [C, C]) = \kappa([\mathfrak{h}, C], C) = 0$; apply Step 3.

Step 6: C is abelian. Otherwise $[C, C]$ is a nonzero ideal of the nilpotent Lie algebra C. The operators $\operatorname{ad}_C x$ restricted to $[C, C]$ are nilpotent, so by Theorem 13.5.5 they have a common null vector: there is $z \neq 0$ in $[C, C]$ with $[C, z] = 0$. By Steps 2 and 5, z is not semisimple, so $z_n \neq 0$; and $z_n \in C$ with $\operatorname{ad} z_n$ a polynomial in $\operatorname{ad} z$, which kills C, so $[z_n, C] = 0$. For $y \in C$, $\operatorname{ad} z_n$ is nilpotent and commutes with $\operatorname{ad} y$, so $\kappa(z_n, y) = 0$. This contradicts Proposition 13.9.3(4).

Step 7: $C = \mathfrak{h}$. Otherwise there is $x \in C \setminus \mathfrak{h}$, and $x_n = x - x_s \neq 0$ lies in C by Steps 1 and 2. Since C is abelian, $\operatorname{ad} x_n$ commutes with every $\operatorname{ad} y$, $y \in C$, so $\kappa(x_n, C) = 0$ as in Step 6; again a contradiction. □

Since $\kappa|_\mathfrak{h}$ is nondegenerate, every $\lambda \in \mathfrak{h}^*$ is $\kappa(t_\lambda, -)$ for a unique $t_\lambda \in \mathfrak{h}$, and $\lambda \mapsto t_\lambda$ is a linear isomorphism $\mathfrak{h}^* \to \mathfrak{h}$. We transport κ to the symmetric bilinear form $(\lambda, \mu) = \kappa(t_\lambda, t_\mu)$ on $\mathfrak{h}^*$, which is nondegenerate.

Proposition 13.9.5. 1. Φ *spans* $\mathfrak{h}^*$.

2. *If* $\alpha \in \Phi$, *then* $-\alpha \in \Phi$.

3. *If* $\alpha \in \Phi$, $x \in \mathfrak{g}_\alpha$ *and* $y \in \mathfrak{g}_{-\alpha}$, *then* $[x, y] = \kappa(x, y)t_\alpha$.

4. *If* $\alpha \in \Phi$, *then* $(\alpha, \alpha) = \alpha(t_\alpha) \neq 0$.

5. *If* $\alpha \in \Phi$ *and* $0 \neq x_\alpha \in \mathfrak{g}_\alpha$, *there is* $y_\alpha \in \mathfrak{g}_{-\alpha}$ *such that* x_α, y_α *and* $h_\alpha = [x_\alpha, y_\alpha]$ *span a subalgebra* S_α *isomorphic to* $\mathfrak{sl}_2$, *by* $x_\alpha \mapsto e$, $y_\alpha \mapsto f$, $h_\alpha \mapsto h$. *The element* $h_\alpha = 2t_\alpha/(\alpha, \alpha)$, *the* coroot *of* α, *does not depend on the choices,* $\alpha(h_\alpha) = 2$, *and* $h_{-\alpha} = -h_\alpha$.

Proof. (1) Otherwise some $h \neq 0$ in $\mathfrak{h}$ satisfies $\alpha(h) = 0$ for all $\alpha \in \Phi$. Then $[h, \mathfrak{g}_\alpha] = 0$ for all roots and $[h, \mathfrak{h}] = 0$, so h is central (Theorem 13.9.4), contradicting semisimplicity.

(2) If $-\alpha \notin \Phi$, then $\kappa(\mathfrak{g}_\alpha, \mathfrak{g}_\beta) = 0$ for all β with $\mathfrak{g}_\beta \neq 0$ (Proposition 13.9.3(3)), so $\mathfrak{g}_\alpha \perp \mathfrak{g}$ and $\mathfrak{g}_\alpha = 0$, which is absurd.

(3) $[x, y] \in \mathfrak{g}_0 = \mathfrak{h}$, and for $h \in \mathfrak{h}$, $\kappa(h, [x, y]) = \kappa([h, x], y) = \alpha(h)\kappa(x, y) = \kappa(h, \kappa(x, y)t_\alpha)$. As $\kappa|_\mathfrak{h}$ is nondegenerate, $[x, y] = \kappa(x, y)t_\alpha$.

(4) Suppose $\alpha(t_\alpha) = 0$. For $x \neq 0$ in $\mathfrak{g}_\alpha$, $\kappa(x, \mathfrak{g}_{-\alpha}) \neq 0$, since x is orthogonal to all other $\mathfrak{g}_\beta$ and κ is nondegenerate; choose $y \in \mathfrak{g}_{-\alpha}$ with $\kappa(x, y) = 1$, so that $[x, y] = t_\alpha$ by (3). Then $[t_\alpha, x] = \alpha(t_\alpha)x = 0$ and $[t_\alpha, y] = 0$, so $S = \operatorname{span}(x, y, t_\alpha)$ is a solvable subalgebra, with $[S, S] = \mathbb{C}t_\alpha$. By Lie's theorem applied to $\operatorname{ad} S \subseteq \mathfrak{gl}(\mathfrak{g})$, the element $\operatorname{ad} t_\alpha \in [\operatorname{ad} S, \operatorname{ad} S]$ is strictly upper triangular in a suitable basis, hence nilpotent. It is also diagonalisable, as $t_\alpha \in \mathfrak{h}$; so $\operatorname{ad} t_\alpha = 0$ and t_α is central, hence 0, contradicting $\alpha \neq 0$.

(5) Choose $y_\alpha \in \mathfrak{g}_{-\alpha}$ with $\kappa(x_\alpha, y_\alpha) = 2/(\alpha,\alpha)$, which is possible as in (4). By (3), $h_\alpha = [x_\alpha, y_\alpha] = 2t_\alpha/(\alpha,\alpha)$, so $\alpha(h_\alpha) = 2$, $[h_\alpha, x_\alpha] = 2x_\alpha$ and $[h_\alpha, y_\alpha] = -2y_\alpha$. The three elements are linearly independent (they lie in $\mathfrak{g}_\alpha$, $\mathfrak{g}_{-\alpha}$, $\mathfrak{h}$ and are nonzero), and their brackets are those of e, f, h. Since $t_{-\alpha} = -t_\alpha$, $h_{-\alpha} = -h_\alpha$. □

So $\mathfrak{g}$ is a representation of each $S_\alpha \cong \mathfrak{sl}_2$, by ad, and Section 13.6 applies. In such a representation M the eigenvalues of h_α, the *weights*, are integers, M is a direct sum of irreducible representations $V(m)$, and since $V(m)$ has the weights $m, m-2, \dots, -m$, each with multiplicity one, the number of summands is $\dim M_0 + \dim M_1$, where M_j is the j-eigenspace of h_α (Theorems 13.6.2 and 13.6.3).

Theorem 13.9.6. *Let $\alpha, \beta \in \Phi$.*

1. $\dim \mathfrak{g}_\alpha = 1$, *and the only multiples $c\alpha$, $c \in \mathbb{C}$, of α that are roots are α and $-\alpha$.*
2. $\beta(h_\alpha) \in \mathbb{Z}$, *and $\beta - \beta(h_\alpha)\alpha \in \Phi$.*
3. *Let $\beta \neq \pm\alpha$, and let r, q be the largest integers such that $\beta - r\alpha$ and $\beta + q\alpha$ are roots. Then $\beta + i\alpha \in \Phi$ for all $-r \le i \le q$ (the α-*string through β *is unbroken), and $\beta(h_\alpha) = r - q$.*
4. *If $\alpha + \beta \in \Phi$, then $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] = \mathfrak{g}_{\alpha+\beta}$.*
5. $\mathfrak{h}$ *is spanned by the coroots h_α, and $\mathfrak{g}$ is generated as a Lie algebra by the root spaces.*

Proof. (1) Let $M = \mathfrak{h} \oplus \bigoplus_{c\neq 0} \mathfrak{g}_{c\alpha}$. By Proposition 13.9.3(1) it is stable under ad S_α, and h_α acts on $\mathfrak{g}_{c\alpha}$ by $c\alpha(h_\alpha) = 2c$. So $2c \in \mathbb{Z}$ whenever $c\alpha \in \Phi$, and the 0-weight space of M is $\mathfrak{h}$. Now $\mathfrak{h} = \ker\alpha \oplus \mathbb{C}h_\alpha$, and S_α acts by 0 on $\ker\alpha$: $[x_\alpha, h] = -\alpha(h)x_\alpha = 0$ and $[y_\alpha, h] = 0$ for $h \in \ker\alpha$. So $\ker\alpha \oplus S_\alpha$ is a subrepresentation of M, and by Theorem 13.6.3 it has a complementary subrepresentation M'. The 0-weight space of M is contained in $\ker\alpha \oplus S_\alpha$, so M' has no weight 0, hence no summand $V(m)$ with m even. Thus the even weights of M are those of $\ker\alpha \oplus S_\alpha$, namely 0 and ± 2; as $\mathfrak{g}_{2\alpha}$ would have weight 4, $2\alpha \notin \Phi$. This holds for every root, so $\frac{1}{2}\alpha$ is not a root either (α would be twice a root). Hence M has no weight 1, M' has no summand $V(m)$ with m odd, and $M' = 0$. So $M = \ker\alpha \oplus S_\alpha$: $\mathfrak{g}_\alpha = \mathbb{C}x_\alpha$, and $\mathfrak{g}_{c\alpha} = 0$ for $c \neq 0, \pm 1$.

(2) and (3) Let $\beta \neq \pm\alpha$ and $K = \bigoplus_{i\in\mathbb{Z}} \mathfrak{g}_{\beta+i\alpha}$, a subrepresentation of S_α. No $\beta + i\alpha$ is 0, by (1), so each summand is a root space, of dimension 1, or zero. The weight of $\mathfrak{g}_{\beta+i\alpha}$ is $\beta(h_\alpha) + 2i$; these are integers, so $\beta(h_\alpha) \in \mathbb{Z}$, they are distinct, and they all have the same parity. So $\dim K_0 + \dim K_1 = 1$, and K is irreducible, $K \cong V(m)$. The weights of $V(m)$ form the unbroken string $m, m-2, \dots, -m$, so the i with $\beta + i\alpha \in \Phi$ form an interval $[-r, q]$, and $m = \beta(h_\alpha) + 2q$, $-m = \beta(h_\alpha) - 2r$. Hence $\beta(h_\alpha) = r - q$, and $\beta - \beta(h_\alpha)\alpha = \beta + (q-r)\alpha$ is a root, as $-r \le q - r \le q$. For $\beta = \pm\alpha$, (2) holds since $\pm\alpha(h_\alpha) = \pm 2$ and $-\beta \in \Phi$.

(4) Since 2α and 0 are not roots, $\beta \neq \pm\alpha$, and $K \cong V(m)$ as above, with $\mathfrak{g}_\beta$ and $\mathfrak{g}_{\alpha+\beta}$ the weight spaces of weights $j = \beta(h_\alpha)$ and $j + 2 \le m$. In $V(m)$, e maps the weight space $m - 2i$ onto the weight space $m - 2i + 2$ for $1 \le i \le m$, since $ev_i = (m - i + 1)v_{i-1}$ (Theorem 13.6.2). So ad $x_\alpha : \mathfrak{g}_\beta \to \mathfrak{g}_{\alpha+\beta}$ is nonzero, and onto, both spaces being one-dimensional.

(5) The coroots are nonzero multiples of the t_α, and the t_α span $\mathfrak{h}$ because Φ spans $\mathfrak{h}^*$. As $h_\alpha = [x_\alpha, y_\alpha]$, the subalgebra generated by the root spaces contains $\mathfrak{h}$, hence everything. □

Corollary 13.9.7 (Dimension from the roots)**.** $\dim \mathfrak{g} = \dim \mathfrak{h} + |\Phi|$*: the dimension of a semisimple Lie algebra is its rank plus the number of its roots. The number of roots is even, as $\alpha \mapsto -\alpha$ is a fixed point free involution of Φ.*

Proof. $\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha\in\Phi} \mathfrak{g}_\alpha$ by Theorem 13.9.4, each $\mathfrak{g}_\alpha$ is a line by Theorem 13.9.6(1), and $-\Phi = \Phi$ by Proposition 13.9.5(2). □

For example $\mathfrak{sl}_n$ has rank $n-1$ and $n(n-1)$ roots, and $(n-1)+n(n-1) = n^2-1$ (Example 13.9.9).

Theorem 13.9.8. *1. For $h, h' \in \mathfrak{h}$, $\kappa(h,h') = \sum_{\gamma\in\Phi} \gamma(h)\gamma(h')$. For $\lambda \in \mathfrak{h}^*$ and $\alpha \in \Phi$, $\lambda(h_\alpha) = 2(\lambda,\alpha)/(\alpha,\alpha)$.*

2. *$(\alpha,\beta) \in \mathbb{Q}$ for all $\alpha, \beta \in \Phi$.*

3. *Let $E_\mathbb{Q}$ be the $\mathbb{Q}$-span of Φ in $\mathfrak{h}^*$. Every basis of $\mathfrak{h}^*$ consisting of roots is a basis of $E_\mathbb{Q}$ over $\mathbb{Q}$; so $\dim_\mathbb{Q} E_\mathbb{Q} = \dim \mathfrak{h}$, the* rank *of $\mathfrak{g}$.*

4. *The form $(\ ,\ )$ is positive definite on $E_\mathbb{Q}$, and extends to an inner product on the real vector space $E = \mathbb{R}\otimes_\mathbb{Q} E_\mathbb{Q}$.*

In E, with $\langle\beta,\alpha\rangle = 2(\beta,\alpha)/(\alpha,\alpha)$:

(R1) Φ is finite, spans E, and does not contain 0;

(R2) the only multiples of $\alpha \in \Phi$ in Φ are $\pm\alpha$;

(R3) for $\alpha,\beta \in \Phi$, $\sigma_\alpha(\beta) = \beta - \langle\beta,\alpha\rangle\alpha \in \Phi$;

(R4) for $\alpha,\beta \in \Phi$, $\langle\beta,\alpha\rangle \in \mathbb{Z}$.

Proof. (1) $\operatorname{ad} h \operatorname{ad} h'$ is 0 on $\mathfrak{h}$ and $\gamma(h)\gamma(h')$ on the line $\mathfrak{g}_\gamma$. And $\lambda(h_\alpha) = \kappa(t_\lambda, h_\alpha) = 2\kappa(t_\lambda,t_\alpha)/(\alpha,\alpha)$.

(2) By (1), $(\lambda,\mu) = \sum_\gamma \gamma(t_\lambda)\gamma(t_\mu) = \sum_\gamma(\gamma,\lambda)(\gamma,\mu)$. For $\beta\in\Phi$, dividing $(\beta,\beta) = \sum_\gamma(\gamma,\beta)^2$ by $(\beta,\beta)^2 \neq 0$ gives $1/(\beta,\beta) = \frac{1}{4}\sum_\gamma \gamma(h_\beta)^2$, which is rational by Theorem 13.9.6(2). So $(\beta,\beta)\in\mathbb{Q}$, and $(\alpha,\beta) = \frac{1}{2}\alpha(h_\beta)(\beta,\beta) \in \mathbb{Q}$.

(3) Let $\alpha_1,\dots,\alpha_l \in \Phi$ be a basis of $\mathfrak{h}^*$, and $\beta = \sum_i c_i\alpha_i \in \Phi$ with $c_i \in \mathbb{C}$. Then $(\beta,\alpha_j) = \sum_i c_i(\alpha_i,\alpha_j)$ for all j. The matrix $((\alpha_i,\alpha_j))$ has rational entries by (2) and is invertible, as $(\ ,\ )$ is nondegenerate; so by Cramer's rule the c_i are rational. Hence the α_i span $E_\mathbb{Q}$ over $\mathbb{Q}$, and they are linearly independent over $\mathbb{Q}$, even over $\mathbb{C}$.

(4) For $\lambda \in E_\mathbb{Q}$, the numbers (γ,λ) are rational, and $(\lambda,\lambda) = \sum_\gamma(\gamma,\lambda)^2 \geq 0$, with equality only if $(\gamma,\lambda) = 0$ for all roots γ, that is, $\lambda = 0$, since Φ spans $\mathfrak{h}^*$. In the basis (α_i) the Gram matrix G is a rational symmetric matrix with $x^TGx > 0$ for $x \in \mathbb{Q}^l \setminus 0$; by density of $\mathbb{Q}^l$ in $\mathbb{R}^l$ and continuity, $x^TGx \geq 0$ for all $x \in \mathbb{R}^l$. A real eigenvector x of G with eigenvalue μ (Theorem 11.10.6) gives $\mu|x|^2 = x^TGx \geq 0$, and $\mu \neq 0$ since $\det G \neq 0$; so all eigenvalues are positive, and G defines an inner product on $E = \mathbb{R}\otimes_\mathbb{Q} E_\mathbb{Q} = \mathbb{R}^l$.

(R1) is clear, (R2) is Theorem 13.9.6(1) (a real multiple of α lying in $E_\mathbb{Q}$ is a rational multiple), and (R3), (R4) are Theorem 13.9.6(2), since $\langle\beta,\alpha\rangle = \beta(h_\alpha)$ by (1). □

Example 13.9.9. *The roots of $\mathfrak{sl}_n$.* Let $\mathfrak{h} \subseteq \mathfrak{sl}_n(\mathbb{C})$ be the diagonal matrices of trace 0, and $\varepsilon_i \in \mathfrak{h}^*$ the i-th diagonal entry. Since $[h, E_{ij}] = (\varepsilon_i(h) - \varepsilon_j(h))E_{ij}$, $\mathfrak{h}$ is toral. Its centraliser is $\mathfrak{h}$: choosing h with distinct diagonal entries, $[h,x] = \sum_{i\neq j}(h_i - h_j)x_{ij}E_{ij}$ vanishes only if x is diagonal. A toral subalgebra containing $\mathfrak{h}$ is abelian (Lemma 13.9.2), hence contained in $C(\mathfrak{h}) = \mathfrak{h}$; so $\mathfrak{h}$ is a Cartan subalgebra. The roots are $\varepsilon_i - \varepsilon_j$, $i \neq j$, with root spaces $\mathbb{C}E_{ij}$; there are $n(n-1)$ of them, and the rank is $n-1$. With $\kappa(x,y) = 2n\operatorname{tr}(xy)$ (Example 13.7.9), for $\alpha = \varepsilon_i - \varepsilon_j$ one finds $t_\alpha = (E_{ii} - E_{jj})/2n$, $(\alpha,\alpha) = 1/n$ and $h_\alpha = E_{ii} - E_{jj}$, and S_α is the copy of $\mathfrak{sl}_2$ spanned by E_{ij}, E_{ji} and $E_{ii} - E_{jj}$. For distinct i, j, l, $(\varepsilon_i - \varepsilon_j, \varepsilon_j - \varepsilon_l) = -1/2n$. So all roots have the same length, and the angle between $\varepsilon_i - \varepsilon_j$ and $\varepsilon_j - \varepsilon_l$ is $2\pi/3$. Concretely, E is the hyperplane $x_1 + \cdots + x_n = 0$ of $\mathbb{R}^n$ with $\frac{1}{2n}$ times the standard inner product, and $\Phi = \{e_i - e_j : i \neq j\}$; this root system is called A_{n-1}. For $n = 2$ there are two roots $\pm\alpha$, with $\alpha(h) = 2$.

Counterexample 13.9.10. A maximal abelian subalgebra need not be a Cartan subalgebra. In $\mathfrak{sl}_2$, $[e, ae + bh + cf] = -2be + ch$ vanishes only for $b = c = 0$, so $\mathbb{C}e$ is a maximal abelian subalgebra; but it consists of nilpotent elements, and it is not toral. By contrast $\mathbb{C}h$ is a Cartan subalgebra. And over $\mathbb{R}$ the theory has to be modified: in $\mathfrak{so}(3)$, for the infinitesimal rotation $L_3 = E_{21} - E_{12}$ the operator $\operatorname{ad} L_3$ has eigenvalues $0, \pm i$, and in fact no nonzero element has $\operatorname{ad} x$ diagonalisable over $\mathbb{R}$; over $\mathbb{C}$, $\mathbb{C}L_3$ is a Cartan subalgebra of $\mathfrak{so}_3(\mathbb{C})$.

Remark 13.9.11. All Cartan subalgebras of a semisimple Lie algebra over $\mathbb{C}$ are conjugate under the group of automorphisms generated by the $\exp(\operatorname{ad} x)$, x nilpotent [Hum72, Section 16]. Hence the root system does not depend, up to isomorphism, on the choice of $\mathfrak{h}$, and the rank is an invariant of $\mathfrak{g}$.

13.10 Root systems and the classification

The properties (R1)–(R4) of Theorem 13.9.8 are purely Euclidean, and they turn out to determine the Lie algebra.

Definition 13.10.1. A *root system* in a finite-dimensional real inner product space E is a subset Φ satisfying (R1)–(R4) of Theorem 13.9.8, where for $\alpha \neq 0$

$$\langle \beta, \alpha \rangle = \frac{2(\beta, \alpha)}{(\alpha, \alpha)}, \qquad \sigma_\alpha(\beta) = \beta - \langle \beta, \alpha \rangle \alpha.$$

Its *rank* is $\dim E$. The *Weyl group* W is the subgroup of the orthogonal group of E generated by the reflections σ_α, $\alpha \in \Phi$. An isomorphism of root systems $(E, \Phi) \to (E', \Phi')$ is a linear isomorphism ϕ with $\phi(\Phi) = \Phi'$ and $\langle \phi\beta, \phi\alpha \rangle = \langle \beta, \alpha \rangle$. Φ is *irreducible* if it is not the union of two nonempty subsets orthogonal to each other.

σ_α is the orthogonal reflection in the hyperplane $\alpha^\perp$: it fixes $\alpha^\perp$ and sends α to $-\alpha$. By (R3) every $w \in W$ permutes Φ, and since Φ spans E, w is determined by this permutation; so W is finite. Note that $\langle \beta, \alpha \rangle$ is linear in β but not in α. The vectors $\alpha^\vee = 2\alpha/(\alpha, \alpha)$ form a root system as well, the *dual* root system; for the root system of a Lie algebra, $\alpha^\vee$ corresponds to the coroot h_α under the identification of $\mathfrak{h}$ with $\mathfrak{h}^*$.

Lemma 13.10.2. *Let $\alpha, \beta \in \Phi$ with $\beta \neq \pm\alpha$, and θ the angle between them. Then $\langle \alpha, \beta \rangle \langle \beta, \alpha \rangle = 4\cos^2\theta \in \{0, 1, 2, 3\}$. If $(\beta, \beta) \geq (\alpha, \alpha)$ and $(\alpha, \beta) \neq 0$, then $\langle \alpha, \beta \rangle = \pm 1$ and $(\beta, \beta)/(\alpha, \alpha) = |\langle \beta, \alpha \rangle| \in \{1, 2, 3\}$; so the possible pairs are*

$$\theta = \tfrac{\pi}{2},\ \tfrac{\pi}{3},\ \tfrac{2\pi}{3},\ \tfrac{\pi}{4},\ \tfrac{3\pi}{4},\ \tfrac{\pi}{6},\ \tfrac{5\pi}{6}, \qquad \frac{(\beta, \beta)}{(\alpha, \alpha)} = \text{any},\ 1,\ 1,\ 2,\ 2,\ 3,\ 3.$$

Moreover, if $(\alpha, \beta) > 0$ then $\alpha - \beta \in \Phi$, and if $(\alpha, \beta) < 0$ then $\alpha + \beta \in \Phi$.

Proof. $\langle \alpha, \beta \rangle \langle \beta, \alpha \rangle = 4(\alpha, \beta)^2/((\alpha, \alpha)(\beta, \beta)) = 4\cos^2\theta$ is an integer by (R4), and it is less than 4 because α and β are not proportional (by (R2)), so the Cauchy–Schwarz inequality is strict. The two integers $\langle \alpha, \beta \rangle$ and $\langle \beta, \alpha \rangle$ have the sign of (α, β), and $|\langle \alpha, \beta \rangle| \leq |\langle \beta, \alpha \rangle|$ when $(\beta, \beta) \geq (\alpha, \alpha)$; if their product is 1, 2 or 3, the smaller one is ± 1, and $\langle \beta, \alpha \rangle / \langle \alpha, \beta \rangle = (\beta, \beta)/(\alpha, \alpha)$. If $(\alpha, \beta) > 0$, one of $\langle \alpha, \beta \rangle, \langle \beta, \alpha \rangle$ is 1: in the first case $\sigma_\beta(\alpha) = \alpha - \beta \in \Phi$, and in the second $\sigma_\alpha(\beta) = \beta - \alpha \in \Phi$, so $\alpha - \beta = \sigma_{\alpha-\beta}(\beta - \alpha) \in \Phi$. If $(\alpha, \beta) < 0$, apply this to α and $-\beta = \sigma_\beta(\beta)$. □

Example 13.10.3. In rank 1 the only root system is $A_1 = \{\pm\alpha\}$, by (R2). In rank 2 there are four, up to isomorphism [Hum72, Section 9.3]; one checks (R1)–(R4) directly.

1. $A_1 \times A_1 = \{\pm e_1, \pm e_2\}$ in $\mathbb{R}^2$, reducible; it is the root system of $\mathfrak{sl}_2 \times \mathfrak{sl}_2$.

2. $A_2 = \{\pm(\varepsilon_1 - \varepsilon_2), \pm(\varepsilon_2 - \varepsilon_3), \pm(\varepsilon_1 - \varepsilon_3)\}$ in the plane $x_1 + x_2 + x_3 = 0$ of $\mathbb{R}^3$: six roots of equal length at angles $\pi/3$, the root system of $\mathfrak{sl}_3$ (Example 13.9.9).

3. $B_2 = \{\pm e_1, \pm e_2, \pm e_1 \pm e_2\}$: four short and four long roots, at angles $\pi/4$; it is also called C_2, the root system of $\mathfrak{sp}_4$ (Exercise 13.12.11).

4. G_2: in the plane $x_1 + x_2 + x_3 = 0$, the six short roots of A_2 together with the six long roots $\pm(2\varepsilon_1 - \varepsilon_2 - \varepsilon_3)$, $\pm(2\varepsilon_2 - \varepsilon_1 - \varepsilon_3)$, $\pm(2\varepsilon_3 - \varepsilon_1 - \varepsilon_2)$; consecutive roots make angles $\pi/6$, and long roots are $\sqrt{3}$ times longer than short ones.

Definition 13.10.4. A *base* of a root system Φ is a subset Δ that is a basis of E such that every root is $\beta = \sum_{\alpha\in\Delta} k_\alpha \alpha$ with integer coefficients k_α that are either all ≥ 0 or all ≤ 0. The elements of Δ are the *simple roots*, the roots with all $k_\alpha \geq 0$ are *positive* ($\beta > 0$), and they form a set Φ^+ with $\Phi = \Phi^+ \sqcup -\Phi^+$. The *height* of β is $\sum_\alpha k_\alpha$.

Theorem 13.10.5. *Let $\gamma \in E$ be* regular, *that is, $(\gamma, \alpha) \neq 0$ for all $\alpha \in \Phi$ (such γ exist, see the end of the proof). Let $\Phi^+(\gamma) = \{\alpha \in \Phi : (\gamma, \alpha) > 0\}$, and let $\Delta(\gamma)$ be the set of $\alpha \in \Phi^+(\gamma)$ that are not the sum of two elements of $\Phi^+(\gamma)$. Then $\Delta(\gamma)$ is a base, with positive roots $\Phi^+(\gamma)$, and $(\alpha, \beta) \leq 0$ for distinct $\alpha, \beta \in \Delta(\gamma)$.*

Proof. Every $\beta \in \Phi^+(\gamma)$ is a non-negative integer combination of $\Delta(\gamma)$. Otherwise choose such a β with (γ, β) minimal. It is not in $\Delta(\gamma)$, so $\beta = \beta_1 + \beta_2$ with $\beta_i \in \Phi^+(\gamma)$; as $(\gamma, \beta) = (\gamma, \beta_1) + (\gamma, \beta_2)$ with both terms positive, each $(\gamma, \beta_i) < (\gamma, \beta)$, so each β_i is such a combination, and so is β.

$(\alpha, \beta) \leq 0$ for distinct $\alpha, \beta \in \Delta(\gamma)$. Otherwise $\alpha - \beta \in \Phi$ by Lemma 13.10.2, and $\alpha - \beta$ or $\beta - \alpha$ lies in $\Phi^+(\gamma)$; then $\alpha = \beta + (\alpha - \beta)$ or $\beta = \alpha + (\beta - \alpha)$ is decomposable.

$\Delta(\gamma)$ is linearly independent. Suppose $\sum_\alpha r_\alpha \alpha = 0$, and separate the terms: $\varepsilon = \sum_{\alpha\in A} s_\alpha \alpha = \sum_{\beta\in B} t_\beta \beta$ with disjoint $A, B \subseteq \Delta(\gamma)$ and $s_\alpha, t_\beta > 0$. Then $(\varepsilon, \varepsilon) = \sum s_\alpha t_\beta (\alpha, \beta) \leq 0$, so $\varepsilon = 0$; and $0 = (\gamma, \varepsilon) = \sum s_\alpha (\gamma, \alpha)$ with all $(\gamma, \alpha) > 0$ forces $A = \emptyset$, and similarly $B = \emptyset$.

Since $\Phi = \Phi^+(\gamma) \sqcup -\Phi^+(\gamma)$ spans E, so does $\Delta(\gamma)$, and it is a base. Regular elements exist: in coordinates, $\gamma \mapsto \prod_{\alpha\in\Phi}(\gamma, \alpha)$ is a product of nonzero linear polynomials, hence a nonzero polynomial, and a nonzero real polynomial does not vanish everywhere on $\mathbb{R}^l$. □

Lemma 13.10.6. *Let Δ be a base and $\alpha \in \Delta$. Then σ_α permutes $\Phi^+ \setminus \{\alpha\}$. Consequently $\rho = \frac{1}{2}\sum_{\beta\in\Phi^+} \beta$ satisfies $\sigma_\alpha(\rho) = \rho - \alpha$ and $\langle \rho, \alpha \rangle = 1$ for every simple root α.*

Proof. Let $\beta = \sum_{\delta\in\Delta} k_\delta \delta \in \Phi^+$, $\beta \neq \alpha$. By (R2), β is not a multiple of α, so $k_\delta > 0$ for some $\delta \neq \alpha$. The coefficient of δ in $\sigma_\alpha(\beta) = \beta - \langle \beta, \alpha \rangle \alpha$ is still $k_\delta > 0$, so $\sigma_\alpha(\beta)$ is a positive root, different from α. As σ_α is injective and $\sigma_\alpha(\alpha) = -\alpha$, $\sigma_\alpha(2\rho) = 2\rho - 2\alpha$. Comparing with $\sigma_\alpha(\rho) = \rho - \langle \rho, \alpha \rangle \alpha$ gives $\langle \rho, \alpha \rangle = 1$. □

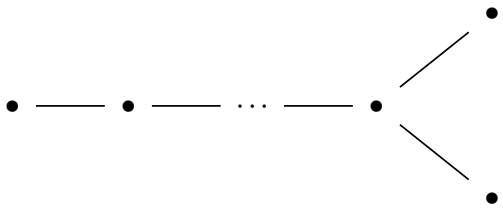
Further facts about bases, which we quote [Hum72, Sections 10.1 and 10.3]: every base is $\Delta(\gamma)$ for some regular γ; the Weyl group acts simply transitively on the set of bases and is generated by the simple reflections σ_α, $\alpha \in \Delta$; and every root is W-conjugate to a simple root.

Definition 13.10.7. Let $\Delta = \{\alpha_1, \ldots, \alpha_l\}$ be a base. The *Cartan matrix* is the integer matrix $(\langle \alpha_i, \alpha_j \rangle)_{i,j}$. Its diagonal entries are 2, and by Theorem 13.10.5 and Lemma 13.10.2 its other entries lie in $\{0, -1, -2, -3\}$. The *Dynkin diagram* has a vertex for each simple root, and α_i and α_j ($i \neq j$) are joined by $\langle \alpha_i, \alpha_j \rangle \langle \alpha_j, \alpha_i \rangle \in \{0, 1, 2, 3\}$ edges; when two joined roots have different lengths, the edges carry an arrow pointing to the shorter one.

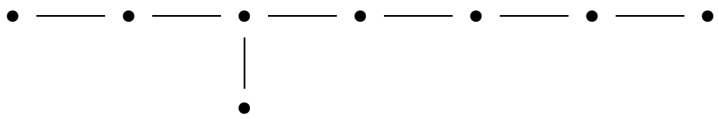
By Lemma 13.10.2 the Dynkin diagram determines the Cartan matrix, and the Cartan matrix determines the root system up to isomorphism, because Φ is the set of images of the simple roots under the group generated by the simple reflections, and these act by $\sigma_{\alpha_j}(\alpha_i) = \alpha_i - \langle \alpha_i, \alpha_j \rangle \alpha_j$ [Hum72, Section 11.1]. The root system is irreducible if and only if its Dynkin diagram is connected, and in general it is the orthogonal union of the irreducible root systems belonging to the connected components.

Theorem 13.10.8 (Classification of root systems)**.** *The connected Dynkin diagrams are those of the following list, and each belongs to exactly one irreducible root system up to isomorphism [Hum72, Sections 11.4 and 12.1].*

1. *A_l ($l \geq 1$), a chain of l vertices joined by single edges:*



2. *B_l ($l \geq 2$), a chain whose last edge is double, with the arrow pointing to the last (short) root:*



3. *C_l ($l \geq 3$), the same chain with the arrow reversed (the last root is long):*

4. *D_l ($l \geq 4$), a chain of $l-2$ vertices whose last vertex is joined to two further vertices:*

5. *E_6, E_7, E_8, a chain of $5, 6, 7$ vertices with one more vertex joined to the third one; for E_8:*

6. *F_4, a chain of four vertices whose middle edge is double:*

7. *G_2, two vertices joined by a triple edge, with the arrow pointing to the short root.*

The restrictions on l avoid repetitions: $B_1 = C_1 = A_1$, $C_2 = B_2$, $D_2 = A_1 \times A_1$ and $D_3 = A_3$. The proof is an exercise in Euclidean geometry: the simple roots, normalised to unit vectors u_i, are linearly independent with $(u_i, u_j) \in \{0, -\frac{1}{2}, -\frac{1}{\sqrt{2}}, -\frac{\sqrt{3}}{2}\}$ for $i \neq j$, and positivity of $(\sum c_i u_i, \sum c_i u_i)$ for well-chosen coefficients excludes all other graphs.

Theorem 13.10.9 (Classification of semisimple Lie algebras)**.** *Let $\mathfrak{g}$ be a semisimple Lie algebra over $\mathbb{C}$ with Cartan subalgebra $\mathfrak{h}$ and root system Φ.*

1. *$\mathfrak{g}$ is simple if and only if Φ is irreducible; the simple ideals of $\mathfrak{g}$ correspond to the irreducible components of Φ.*

2. *Two semisimple Lie algebras are isomorphic if and only if their root systems are isomorphic.*

3. *Every root system is the root system of a semisimple Lie algebra.*

Consequently the simple Lie algebras over $\mathbb{C}$ are, up to isomorphism, exactly one for each diagram of Theorem 13.10.8: the classical algebras $\mathfrak{sl}_{l+1}$ (A_l), $\mathfrak{so}_{2l+1}$ (B_l), $\mathfrak{sp}_{2l}$ (C_l), $\mathfrak{so}_{2l}$ (D_l), of dimensions $l(l+2)$, $l(2l+1)$, $l(2l+1)$, $l(2l-1)$, and five exceptional algebras $\mathfrak{e}_6$, $\mathfrak{e}_7$, $\mathfrak{e}_8$, $\mathfrak{f}_4$, $\mathfrak{g}_2$ of dimensions 78, 133, 248, 52 and 14.

For (1) see [Hum72, Section 14.1], for (2) [Hum72, Sections 14 and 16], and for (3) [Hum72, Section 18], where $\mathfrak{g}$ is constructed by generators x_i, y_i, h_i ($1 \le i \le l$) and relations read off from the Cartan matrix (Serre's theorem). The dimension of $\mathfrak{g}$ is $l + |\Phi|$ (Corollary 13.9.7); the number of roots of each type can be computed from the Cartan matrix, as in Example 13.10.11 below.

Lemma 13.10.10. *Let Δ be a base. Every positive root β that is not simple has a simple root α with $\beta - \alpha \in \Phi^+$. Hence every positive root of height h is a sum $\alpha_{i_1} + \cdots + \alpha_{i_h}$ of simple roots such that every partial sum $\alpha_{i_1} + \cdots + \alpha_{i_j}$ is a root.*

Proof. Write $\beta = \sum_{\alpha\in\Delta} k_\alpha \alpha$ with $k_\alpha \ge 0$. If $(\beta, \alpha) \le 0$ for all $\alpha \in \Delta$, then $(\beta, \beta) = \sum k_\alpha(\beta, \alpha) \le 0$, which is impossible; so $(\beta, \alpha) > 0$ for some simple α, and $\beta - \alpha \in \Phi$ by Lemma 13.10.2 ($\beta \ne \alpha$ as β is not simple, and $\beta \ne -\alpha$ as $\beta > 0$). Since β is not a multiple of α, some k_δ with $\delta \ne \alpha$ is positive, and it is a coefficient of $\beta - \alpha$; so $\beta - \alpha$ is positive, of height one less. The second statement follows by induction on the height. □

Example 13.10.11. *Counting roots from the Cartan matrix.* By the lemma, the positive roots can be listed by height, starting from the simple roots: a root of height $h+1$ is $\beta + \alpha_i$ with β a root of height h and α_i simple. Whether $\beta + \alpha_i$ is a root is decided by the α_i-string through β (Theorem 13.9.6(3); the same holds for every root system [Hum72, Section 9.4]): if r is the largest integer with $\beta - r\alpha_i \in \Phi$, already known from the lower heights, then $q = r - \langle\beta, \alpha_i\rangle$, and $\beta + \alpha_i$ is a root if and only if $q \ge 1$. The numbers $\langle\beta, \alpha_i\rangle$ are computed from the Cartan matrix by linearity in β.

For G_2, with α short and β long, $\langle\alpha, \beta\rangle = -1$ and $\langle\beta, \alpha\rangle = -3$. Height 2: $\alpha+\beta$ (as $(\alpha, \beta) < 0$); 2α and 2β are not roots. Height 3: for $\alpha + \beta$, the α-string goes down to β, so $r = 1$, and $\langle\alpha + \beta, \alpha\rangle = 2 - 3 = -1$, so $q = 2$: $2\alpha + \beta$ and $3\alpha + \beta$ are roots; the β-string has $r = 1$ and $\langle\alpha + \beta, \beta\rangle = -1 + 2 = 1$, so $q = 0$ and $\alpha + 2\beta$ is not a root. Height 4: $3\alpha + \beta$; for $2\alpha + \beta$ the β-string has $r = 0$ and $\langle 2\alpha + \beta, \beta\rangle = -2 + 2 = 0$, so $2\alpha + 2\beta$ is not a root. Height 5: for $3\alpha + \beta$, $r = 0$ for β and $\langle 3\alpha + \beta, \beta\rangle = -3 + 2 = -1$, so $3\alpha + 2\beta$ is a root; $\langle 3\alpha + \beta, \alpha\rangle = 6 - 3 = 3 = r$ with $r = 3$, so $4\alpha + \beta$ is not. Height 6: $\langle 3\alpha + 2\beta, \alpha\rangle = 0$ with $r = 0$, and $\langle 3\alpha + 2\beta, \beta\rangle = -3 + 4 = 1$ with $r = 1$, so nothing more. So G_2 has the six positive roots α, β, $\alpha + \beta$, $2\alpha + \beta$, $3\alpha + \beta$, $3\alpha + 2\beta$, twelve roots in all, and $\dim \mathfrak{g}_2 = 2 + 12 = 14$ (Corollary 13.9.7).

The same computation for the other types gives the number of roots [Hum72, Section 12.1], and with Corollary 13.9.7 the dimension:

1. A_l: $l(l+1)$ roots, $\dim = l + l(l+1) = l(l+2) = (l+1)^2 - 1$, which is $\dim \mathfrak{sl}_{l+1}$;
2. B_l and C_l: $2l^2$ roots (for B_l: $\pm\varepsilon_i$ and $\pm\varepsilon_i \pm \varepsilon_j$, $i < j$), $\dim = l(2l+1)$, which is $\dim \mathfrak{so}_{2l+1} = \binom{2l+1}{2}$ and $\dim \mathfrak{sp}_{2l}$ (Example 13.7.14);
3. D_l: $2l(l-1)$ roots ($\pm\varepsilon_i \pm \varepsilon_j$, $i < j$), $\dim = l(2l-1) = \binom{2l}{2} = \dim \mathfrak{so}_{2l}$;
4. E_6, E_7, E_8, F_4, G_2: 72, 126, 240, 48, 12 roots, and dimensions 78, 133, 248, 52, 14.

Proposition 13.10.12 (Serre's relations)**.** *Let $\mathfrak{g}$ be semisimple with base $\Delta = \{\alpha_1, \ldots, \alpha_l\}$, and choose $e_i = x_{\alpha_i}$, $f_i = y_{\alpha_i}$, $h_i = h_{\alpha_i}$ as in Proposition 13.9.5. With $c_{ij} = \langle\alpha_j, \alpha_i\rangle$, the generators e_i, f_i, h_i of $\mathfrak{g}$ satisfy*

$$[h_i, h_j] = 0, \quad [e_i, f_j] = \delta_{ij} h_i, \quad [h_i, e_j] = c_{ij} e_j, \quad [h_i, f_j] = -c_{ij} f_j, \quad (\operatorname{ad} e_i)^{1-c_{ij}} e_j = 0 = (\operatorname{ad} f_i)^{1-c_{ij}} f_j \ (i \ne j).$$

Proof. $\mathfrak{h}$ is abelian. For $i \neq j$, $[e_i, f_j] \in \mathfrak{g}_{\alpha_i - \alpha_j} = 0$, since a difference of two simple roots has coefficients of both signs and is not a root; and $[e_i, f_i] = h_i$. Next $[h_i, e_j] = \alpha_j(h_i)e_j = \langle \alpha_j, \alpha_i \rangle e_j$ (Theorem 13.9.8(1)), and similarly for f_j. Finally, for $i \neq j$ the α_i-string through α_j has $r = 0$, as $\alpha_j - \alpha_i$ is not a root, so by Theorem 13.9.6(3) it is $\alpha_j, \dots, \alpha_j + q\alpha_i$ with $q = -c_{ij}$; hence $\alpha_j + (1 - c_{ij})\alpha_i$ is not a root, and $(\operatorname{ad} e_i)^{1-c_{ij}} e_j \in \mathfrak{g}_{\alpha_j + (1-c_{ij})\alpha_i} = 0$. The same argument with negative roots gives the relation for the f_i. □

Serre's theorem [Hum72, Section 18.3] says that these relations are a presentation: for every root system with Cartan matrix (c_{ij}), the Lie algebra generated by e_i, f_i, h_i with only these relations is finite-dimensional and semisimple, with the given root system. This gives part (3) of Theorem 13.10.9. For $\mathfrak{sl}_3$, with $e_1 = E_{12}$, $e_2 = E_{23}$, the relations say $[e_1, [e_1, e_2]] = [E_{12}, E_{13}] = 0$ and $[e_2, [e_2, e_1]] = -[E_{23}, E_{13}] = 0$, while $[e_1, e_2] = E_{13} \neq 0$.

13.11 Weights and highest weights

The classification of the representations of $\mathfrak{sl}_2$ by their highest weight m (Theorem 13.6.2) extends to every semisimple Lie algebra. In this section $\mathfrak{g}$ is semisimple over $\mathbb{C}$, $\mathfrak{h}$ is a Cartan subalgebra with roots Φ, Δ is a base, and representations are finite-dimensional. For $\lambda, \mu \in \mathfrak{h}^*$ write $\mu \leq \lambda$ if $\lambda - \mu$ is a sum of positive roots (possibly empty), and put $\langle \lambda, \alpha \rangle = \lambda(h_\alpha) = 2(\lambda, \alpha)/(\alpha, \alpha)$ (Theorem 13.9.8(1)).

Proposition 13.11.1. *Let V be a representation of $\mathfrak{g}$, and for $\lambda \in \mathfrak{h}^*$ let $V_\lambda = \{v : hv = \lambda(h)v \text{ for all } h \in \mathfrak{h}\}$.*

1. *$V = \bigoplus_\lambda V_\lambda$; the λ with $V_\lambda \neq 0$ are the* weights *of V, and* $\dim V_\lambda$ *is the* multiplicity *of λ.*
2. *$\mathfrak{g}_\alpha V_\lambda \subseteq V_{\lambda+\alpha}$.*
3. *Every weight λ is* integral*: $\langle \lambda, \alpha \rangle \in \mathbb{Z}$ for all $\alpha \in \Phi$.*
4. *The multiplicities are invariant under the Weyl group:* $\dim V_\lambda = \dim V_{\sigma_\alpha \lambda}$ *for $\alpha \in \Phi$.*

Proof. (1) The elements of $\mathfrak{h}$ are semisimple, so they act diagonalisably on V (Corollary 13.8.4(2)), and they commute; so they are simultaneously diagonalisable, as for the root space decomposition. (2) For $x \in \mathfrak{g}_\alpha$ and $v \in V_\lambda$, $hxv = xhv + [h, x]v = (\lambda(h) + \alpha(h))xv$. (3) V_λ is contained in the $\lambda(h_\alpha)$-eigenspace of h_α, and h_α has integer eigenvalues on the S_α-representation V (Theorem 13.6.3). (4) Let $m = \langle \lambda, \alpha \rangle$, and replacing λ by $\sigma_\alpha \lambda = \lambda - m\alpha$ if necessary, assume $m \geq 0$. The subspace $U = \bigoplus_{i \in \mathbb{Z}} V_{\lambda + i\alpha}$ is S_α-stable by (2), and $V_{\lambda+i\alpha}$ is its h_α-eigenspace for the eigenvalue $m + 2i$. By Corollary 13.6.4, y_α^m maps the eigenspace $U_m = V_\lambda$ isomorphically onto $U_{-m} = V_{\lambda - m\alpha} = V_{\sigma_\alpha \lambda}$. □

For the adjoint representation, the weights are the roots, of multiplicity 1, and 0, of multiplicity the rank. A *maximal vector* of weight λ is a nonzero $v \in V_\lambda$ with $\mathfrak{g}_\alpha v = 0$ for all $\alpha \in \Phi^+$. An integral weight λ is *dominant* if $\langle \lambda, \alpha \rangle \geq 0$ for all $\alpha \in \Delta$, hence for all $\alpha \in \Phi^+$.

Theorem 13.11.2 (Highest weight)**.** *Let V be an irreducible representation of $\mathfrak{g}$.*

1. *V has a maximal vector v^+, unique up to a scalar. Its weight λ, the* highest weight *of V, satisfies $\mu \leq \lambda$ for every weight μ of V, and* $\dim V_\lambda = 1$*. V is spanned by the vectors $y_1 y_2 \cdots y_k v^+$ with $k \geq 0$ and $y_i \in \mathfrak{g}_{-\beta_i}$, $\beta_i \in \Phi^+$.*
2. *The highest weight is dominant integral.*
3. *Two irreducible representations with the same highest weight are isomorphic.*

Proof. (1) The subspace $\mathfrak{n} = \bigoplus_{\alpha>0} \mathfrak{g}_\alpha$ is a subalgebra, since the sum of two positive roots is positive if it is a root, and by Proposition 13.9.3(1) the bracket $[\mathfrak{n}, \mathfrak{n}]$ involves only roots of height ≥ 2, and inductively the j-th term of the lower central series only roots of height $\geq j$; so $\mathfrak{n}$ is nilpotent. Hence $\mathfrak{b} = \mathfrak{h} \oplus \mathfrak{n}$ is a solvable subalgebra ($[\mathfrak{b}, \mathfrak{b}] \subseteq \mathfrak{n}$; Lemma 13.5.2). By Lie's theorem its image in $\mathfrak{gl}(V)$ has a common eigenvector v^+. Then $v^+ \in V_\lambda$ for some λ, and for $x \in \mathfrak{g}_\alpha$, $\alpha > 0$, the vector xv^+ lies in $V_{\lambda+\alpha} \cap \mathbb{C}v^+ = 0$. So v^+ is a maximal vector.

Let U_k be the span of the vectors $y_1 \cdots y_j v^+$ as in the statement with $j \leq k$, and $U = \bigcup_k U_k$. Clearly U is stable under the $\mathfrak{g}_{-\beta}$, $\beta > 0$, and under $\mathfrak{h}$, which acts on $y_1 \cdots y_j v^+$ by the weight $\lambda - \beta_1 - \cdots - \beta_j$. We show by induction on k that $xU_k \subseteq U_k$ for $x \in \mathfrak{g}_\alpha$, $\alpha > 0$; for $k = 0$, $xv^+ = 0$. For $w = y_1 u$ with $u \in U_{k-1}$, $xw = y_1(xu) + [x, y_1]u$; here $xu \in U_{k-1}$ by induction, and $[x, y_1] \in \mathfrak{g}_{\alpha-\beta_1}$ lies in $\mathfrak{h}$, in a negative root space, or in a positive root space, and in each case $[x, y_1]u \in U_k$ (by induction in the last case). So U is a nonzero subrepresentation, and $U = V$. All weights of V are therefore of the form $\lambda - \beta_1 - \cdots - \beta_j \leq \lambda$, and the weight λ occurs only for $j = 0$, since a nonempty sum of positive roots has positive height; so $V_\lambda = \mathbb{C}v^+$. If w is another maximal vector, of weight μ, the same argument gives $\lambda \leq \mu$, so $\mu = \lambda$ (the relation $\leq$ is antisymmetric, as heights add) and $w \in V_\lambda = \mathbb{C}v^+$.

(2) Integrality is Proposition 13.11.1(3). For $\alpha \in \Delta$, v^+ is killed by x_α and is an eigenvector of h_α with eigenvalue $\langle \lambda, \alpha \rangle$, which is therefore a non-negative integer by Theorem 13.6.2.

(3) Let V, V' be irreducible with maximal vectors v, v' of the same weight λ, and let $W \subseteq V \oplus V'$ be the subrepresentation generated by the maximal vector $w = (v, v')$. As in (1), W is spanned by the vectors $y_1 \cdots y_j w$, all its weights are $\leq \lambda$, and $W_\lambda = \mathbb{C}w$. A subrepresentation $W' \subseteq W$ is the sum of its intersections with the weight spaces, since $\mathfrak{h}$ acts diagonalisably; if $W'_\lambda \neq 0$ it contains w and equals W. So the sum of all proper subrepresentations has no component of weight λ, and it is the unique maximal proper subrepresentation N of W. The two projections $W \to V$ and $W \to V'$ are nonzero ($w \mapsto v, v'$), hence onto, as V and V' are irreducible; their kernels are maximal proper subrepresentations, hence equal to N. So $V \cong W/N \cong V'$. □

Remark 13.11.3. Conversely, for every dominant integral weight λ there is an irreducible representation $V(\lambda)$ with highest weight λ, constructed as the unique irreducible quotient of the Verma module $U(\mathfrak{g}) \otimes_{U(\mathfrak{b})} \mathbb{C}_\lambda$ [Hum72, Section 21]. So the irreducible representations of $\mathfrak{g}$ correspond bijectively to the dominant integral weights, which are the $\sum_i n_i \omega_i$ with $n_i \in \mathbb{Z}_{\geq 0}$, where the *fundamental weights* ω_i are defined by $\langle \omega_i, \alpha_j \rangle = \delta_{ij}$ [Hum72, Section 13]. Its dimension is given by the *Weyl dimension formula* [Hum72, Section 24.3]

$$\dim V(\lambda) = \prod_{\alpha \in \Phi^+} \frac{(\lambda + \rho, \alpha)}{(\rho, \alpha)},$$

with ρ as in Lemma 13.10.6. For $\mathfrak{sl}_2$, with $\Phi^+ = \{\alpha\}$ and $\lambda = m\omega_1 = \frac{m}{2}\alpha$, the formula gives $m + 1$, and $V(\lambda)$ is the representation $V(m)$ of Section 13.6.

Example 13.11.4. For $\mathfrak{sl}_3$ take $\Delta = \{\alpha_1, \alpha_2\}$ with $\alpha_1 = \varepsilon_1 - \varepsilon_2$, $\alpha_2 = \varepsilon_2 - \varepsilon_3$; it is the base $\Delta(\gamma)$ of Theorem 13.10.5 for $\gamma = \varepsilon_1 - \varepsilon_3$, which pairs positively with α_1, α_2 and $\alpha_1 + \alpha_2$. The positive roots are α_1, α_2, $\alpha_1 + \alpha_2 = \varepsilon_1 - \varepsilon_3$, with root vectors E_{12}, E_{23}, E_{13}, the strictly upper triangular matrices, and $\mathfrak{b}$ consists of the upper triangular matrices of trace 0. The coroots are $h_{\alpha_1} = E_{11} - E_{22}$ and $h_{\alpha_2} = E_{22} - E_{33}$.

1. On $\mathbb{C}^3$, e_i has weight ε_i, and e_1 is a maximal vector: its highest weight is $\varepsilon_1 = \omega_1$, since $\varepsilon_1(h_{\alpha_1}) = 1$ and $\varepsilon_1(h_{\alpha_2}) = 0$.

2. On the dual $(\mathbb{C}^3)^*$ the weights are $-\varepsilon_i$, and the highest is $-\varepsilon_3 = \omega_2$.

3. On the adjoint representation the weights are the six roots and 0, with multiplicity 2; the maximal vector is E_{13}, of weight $\alpha_1 + \alpha_2 = \omega_1 + \omega_2$.

In each case the Weyl group S_3, which permutes the ε_i (Exercise 13.12.12), permutes the weights preserving multiplicities.

13.12 Exercises

Exercise 13.12.1. Let $\mathfrak{sl}_2$ act on $\mathbb{C}^2$ by matrix multiplication. Show that $S^m(\mathbb{C}^2) \cong V(m)$.

Exercise 13.12.2. Show that $V(m) \otimes V(n) \cong \bigoplus_{i=0}^{\min(m,n)} V(m+n-2i)$. (Hint: count weights.)

Solution. The vectors $v_a \otimes w_b$ form a basis of weight vectors, of weight $(m-2a)+(n-2b)$. So the weight $l = m+n-2s$ has multiplicity $c(s) = |\{(a,b) : 0 \le a \le m, 0 \le b \le n, a+b = s\}|$, and for $0 \le s \le (m+n)/2$ one finds $c(s) = \min(s, m, n) + 1$. By Theorem 13.6.3 the representation is a direct sum of $V(l)$'s, and the multiplicity of $V(l)$, $l \ge 0$, is $\dim V_l - \dim V_{l+2} = c(s) - c(s-1)$ (with $c(-1) = 0$), which is 1 for $s \le \min(m,n)$ and 0 otherwise. □

Exercise 13.12.3. Determine the character table of S_4.

Solution. The classes of S_4 are given by cycle types: e (1 element), transpositions (6), double transpositions (3), 3-cycles (8) and 4-cycles (6). So there are five irreducible characters. Besides the trivial character and the sign ε, the standard representation (Proposition 13.3.13) has character χ_3 = (fixed points) $- 1 = (3, 1, -1, 0, -1)$, and $\varepsilon\chi_3 = (3, -1, -1, 0, 1)$ is irreducible by twisting and different from χ_3. The remaining degree is $\sqrt{24 - 1 - 1 - 9 - 9} = 2$. A two-dimensional irreducible representation is obtained by lifting: the Klein group V of Example 13.3.14 is normal in S_4, and $S_4/V \cong S_3$ (the action of S_4 by conjugation on the three nontrivial elements of V has kernel exactly V, since (12), (123) and (1234) move (13)(24) or (12)(34), and so its image has order $24/4 = 6$). Lifting the character $(2, 0, -1)$ of S_3 from Example 13.3.5: a transposition and a 4-cycle map to elements of order 2 in S_3 (the square of a 4-cycle lies in V), a double transposition maps to e, and a 3-cycle to an element of order 3. So

	e	(12)	(12)(34)	(123)	(1234)
class size	1	6	3	8	6
1	1	1	1	1	1
ε	1	−1	1	1	−1
χ_2	2	0	2	−1	0
χ_3	3	1	−1	0	−1
$\varepsilon\chi_3$	3	−1	−1	0	1

As a check, the column of (12) has $\sum |\chi_i|^2 = 1 + 1 + 0 + 1 + 1 = 4 = |C_{S_4}((12))|$, the centraliser being $\{e, (12), (34), (12)(34)\}$. Geometrically, S_4 is the rotation group of the cube, acting on the four long diagonals, and $\varepsilon\chi_3$ is its three-dimensional rotation representation: a 4-cycle is a rotation by $\pi/2$ about an axis through the centres of opposite faces, with trace $1 + 2\cos(\pi/2) = 1$. □

Exercise 13.12.4. Show that a finite group is abelian if and only if all its irreducible complex representations are one-dimensional. (One direction is Proposition 13.3.6; for the other use Theorem 13.3.4.)

Exercise 13.12.5. Let $V = \bigoplus_{k=0}^{2n} V^k$ be a graded finite-dimensional vector space and $L\colon V^k \to V^{k+2}$ a linear map. Suppose there is $\Lambda\colon V^k \to V^{k-2}$ such that, with $H = (k-n)\mathrm{id}$ on V^k, the relations $[H, L] = 2L$, $[H, \Lambda] = -2\Lambda$, $[L, \Lambda] = H$ hold. Show that $L^j\colon V^{n-j} \to V^{n+j}$ is an isomorphism for all $j \ge 0$. (This is the algebraic form of the hard Lefschetz theorem.)

Exercise 13.12.6. Show that every Lie algebra of dimension 2 is either abelian or isomorphic to the Lie algebra with basis x, y and $[x, y] = y$ of Example 13.5.3(3).

Solution. Let u, v be a basis. The bracket is determined by $[u, v]$, as $[u, u] = [v, v] = 0$. If $[u, v] = 0$ the algebra is abelian. Otherwise $y = [u, v]$ spans $[\mathfrak{g}, \mathfrak{g}]$, which is one-dimensional. Complete y to a basis y, x'; then $[x', y] = cy$ for some $c \in k$, as $[x', y] \in [\mathfrak{g}, \mathfrak{g}]$, and $c \neq 0$ because $[x', y]$ spans $[\mathfrak{g}, \mathfrak{g}]$. So $x = x'/c$ satisfies $[x, y] = y$. □

Exercise 13.12.7. Let $\mathfrak{g}$ be the real Lie algebra $\mathbb{R}^3$ with the cross product as bracket (it is isomorphic to the Lie algebra $\mathfrak{so}(3)$ of the rotation group, Chapter 34). Show that $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}$, so that $\mathfrak{g}$ is not solvable, and that it has no ideals other than 0 and itself.

Solution. $e_1 \times e_2 = e_3$, $e_2 \times e_3 = e_1$ and $e_3 \times e_1 = e_2$, so the brackets span everything and $D^i\mathfrak{g} = \mathfrak{g}$ for all i. The cross product satisfies the Jacobi identity, so $\mathfrak{g}$ is a Lie algebra. If $\mathfrak{a}$ is an ideal containing some $a \neq 0$, then $\mathfrak{a} \supseteq a \times \mathbb{R}^3$, and $a \times \mathbb{R}^3 = a^\perp$, since $v \mapsto a \times v$ has kernel $\mathbb{R}a$ and image in $a^\perp$. For an orthonormal basis u, w of $a^\perp$, $u \times w$ is a unit vector orthogonal to u and w, so $u \times w = \pm a/|a|$ lies in $\mathfrak{a}$. Hence $\mathfrak{a} \supseteq a^\perp + \mathbb{R}a = \mathbb{R}^3$. □

Exercise 13.12.8. Show that the Killing form $\operatorname{tr}(\operatorname{ad} x \operatorname{ad} y)$ of a nilpotent Lie algebra is zero.

Solution. By Corollary 13.5.6 and Theorem 13.5.5 applied to $\operatorname{ad}\mathfrak{g}$, there is a basis of $\mathfrak{g}$ in which every $\operatorname{ad} x$ is strictly upper triangular. A product of strictly upper triangular matrices is strictly upper triangular, so it has trace 0. □

Exercise 13.12.9. Compute the Gram matrix of the Killing form of $\mathfrak{sl}_2$ in the basis e, h, f, and the Casimir element $c_{\mathrm{ad}} \in \operatorname{End}(\mathfrak{sl}_2)$ of the adjoint representation (Lemma 13.8.1). Show that c_{ad} is $\frac{1}{4}$ times the Casimir operator C of Theorem 13.6.3 acting on $\mathfrak{sl}_2 \cong V(2)$, and deduce that $c_{\mathrm{ad}} = \mathrm{id}$, in agreement with $\operatorname{tr} c_{\mathrm{ad}} = \dim \mathfrak{sl}_2 = 3$.

Solution. In the basis (e, h, f), $\operatorname{ad} h = \operatorname{diag}(2, 0, -2)$, $\operatorname{ad} e$ sends $h \mapsto -2e$, $f \mapsto h$, and $\operatorname{ad} f$ sends $e \mapsto -h$, $h \mapsto 2f$. So $\kappa(h, h) = 8$, $\kappa(e, f) = \operatorname{tr}(\operatorname{ad} e \operatorname{ad} f) = 4$ (the composite sends $e \mapsto 2e$, $h \mapsto 2h$, $f \mapsto 0$), and the other pairings vanish by Proposition 13.9.3(3); the Gram matrix has 8 in the middle and 4 in the two corners (e, f), (f, e), in agreement with $\kappa = 4\operatorname{tr}(xy)$ (Example 13.7.9). The dual basis of (e, h, f) is $(\frac{1}{4}f, \frac{1}{8}h, \frac{1}{4}e)$, so

$$c_{\mathrm{ad}} = \tfrac{1}{4}\operatorname{ad} e \operatorname{ad} f + \tfrac{1}{8}(\operatorname{ad} h)^2 + \tfrac{1}{4}\operatorname{ad} f \operatorname{ad} e = \tfrac{1}{4}\big(\operatorname{ad} e \operatorname{ad} f + \operatorname{ad} f \operatorname{ad} e + \tfrac{1}{2}(\operatorname{ad} h)^2\big),$$

which is $\frac{1}{4}C$ in the adjoint representation. By the proof of Theorem 13.6.3, C acts on $V(m)$ by $\frac{1}{2}m(m+2)$, which is 4 for $m = 2$; so $c_{\mathrm{ad}} = \mathrm{id}$. □

Exercise 13.12.10. Show that $\mathfrak{sl}_n(\mathbb{C})$ is simple for $n \geq 2$. (Hint: an ideal is stable under $\operatorname{ad}\mathfrak{h}$, $\mathfrak{h}$ the diagonal matrices of trace 0.)

Solution. Let $\mathfrak{a} \neq 0$ be an ideal. It is stable under the commuting diagonalisable operators $\operatorname{ad} h$, $h \in \mathfrak{h}$, so it is the sum of its intersections with $\mathfrak{h}$ and with the root spaces $\mathbb{C}E_{ij}$ (Example 13.9.9). If $\mathfrak{a} \subseteq \mathfrak{h}$, take $h \neq 0$ in $\mathfrak{a}$; its diagonal entries are not all equal, since $\operatorname{tr} h = 0$, say $h_i \neq h_j$, and then $[h, E_{ij}] = (h_i - h_j)E_{ij} \in \mathfrak{a}$ is not in $\mathfrak{h}$, a contradiction. So $\mathfrak{a}$ contains some E_{ij}, $i \neq j$. Then it contains $[E_{ij}, E_{ji}] = E_{ii} - E_{jj}$ and $[E_{ji}, E_{ii} - E_{jj}] = 2E_{ji}$, and for $l \notin \{i, j\}$ also $[E_{li}, E_{ij}] = E_{lj}$ and $[E_{ij}, E_{jl}] = E_{il}$. Repeating with the new matrix units, $\mathfrak{a}$ contains all E_{lm} with $l \neq m$, hence all $E_{ll} - E_{mm} = [E_{lm}, E_{ml}]$, and $\mathfrak{a} = \mathfrak{sl}_n$. Finally $\mathfrak{sl}_n$ is not abelian. □

Exercise 13.12.11. Let $\mathfrak{h} \subseteq \mathfrak{sp}_4(\mathbb{C})$ be the diagonal matrices $h = \operatorname{diag}(a_1, a_2, -a_1, -a_2)$ (Example 13.7.14), and $\varepsilon_i(h) = a_i$. Show that $\mathfrak{h}$ is a Cartan subalgebra, that the roots are $\pm 2\varepsilon_1$, $\pm 2\varepsilon_2$, $\pm(\varepsilon_1 + \varepsilon_2)$, $\pm(\varepsilon_1 - \varepsilon_2)$, that $\kappa(h, h') = 12(a_1a_1' + a_2a_2')$ on $\mathfrak{h}$, and that $\Delta = \{\varepsilon_1 - \varepsilon_2, 2\varepsilon_2\}$ is a base with Cartan matrix $\left(\begin{smallmatrix} 2 & -1 \\ -2 & 2 \end{smallmatrix}\right)$. So the root system is $C_2 = B_2$.

Solution. Write $x = \left(\begin{smallmatrix} A & B \\ C & -A^T \end{smallmatrix}\right)$ and $h = \operatorname{diag}(D, -D)$ with $D = \operatorname{diag}(a_1, a_2)$. Then

$$[h, x] = \begin{pmatrix} [D, A] & DB + BD \\ -(DC + CD) & [D, A]' \end{pmatrix},$$

where $[D, A]' = -[D, A]^T$ is determined by the upper left block. The entries transform as $(DA - AD)_{ij} = (a_i - a_j)A_{ij}$, $(DB + BD)_{ij} = (a_i + a_j)B_{ij}$ and $(DC + CD)_{ij} = (a_i + a_j)C_{ij}$. So $\mathfrak{h}$ is toral, the root vectors are $A = E_{12}, E_{21}$ (roots $\pm(\varepsilon_1 - \varepsilon_2)$), the symmetric $B = E_{11}, E_{22}, E_{12} + E_{21}$ (roots $2\varepsilon_1, 2\varepsilon_2, \varepsilon_1 + \varepsilon_2$) and the corresponding C (their negatives). If $[h, x] = 0$ for h with $a_1, a_2, a_1 \pm a_2$ nonzero, then A is diagonal and $B = C = 0$, so $C(\mathfrak{h}) = \mathfrak{h}$, and $\mathfrak{h}$ is a Cartan subalgebra, as in Example 13.9.9. By Theorem 13.9.8(1),

$$\kappa(h, h') = 2\big[(a_1 - a_2)(a_1' - a_2') + 4a_1a_1' + 4a_2a_2' + (a_1 + a_2)(a_1' + a_2')\big] = 12(a_1a_1' + a_2a_2'),$$

so $(\ ,\ )$ is a multiple of the standard inner product in the coordinates $\varepsilon_1, \varepsilon_2$. With $\alpha_1 = \varepsilon_1 - \varepsilon_2$ and $\alpha_2 = 2\varepsilon_2$, the positive roots α_1, α_2, $\alpha_1 + \alpha_2 = \varepsilon_1 + \varepsilon_2$, $2\alpha_1 + \alpha_2 = 2\varepsilon_1$ are non-negative combinations, so Δ is a base, and $\langle \alpha_1, \alpha_2 \rangle = 2(-2)/4 = -1$, $\langle \alpha_2, \alpha_1 \rangle = 2(-2)/2 = -2$. The four long roots $\pm 2\varepsilon_i$ and the four short roots $\pm\varepsilon_1 \pm \varepsilon_2$ form, after rotating by $\pi/4$ and rescaling, the root system B_2 of Example 13.10.3. □

Exercise 13.12.12. Show that the Weyl group of the root system A_{n-1} of $\mathfrak{sl}_n$ (Example 13.9.9) is the symmetric group S_n, acting on $E = \{x \in \mathbb{R}^n : \sum_i x_i = 0\}$ by permuting the coordinates.

Solution. For $\alpha = e_i - e_j$ and $x \in E$, $\langle x, \alpha \rangle = 2(x \cdot \alpha)/(\alpha \cdot \alpha) = x_i - x_j$ (the factor $\frac{1}{2n}$ cancels), so $\sigma_\alpha(x) = x - (x_i - x_j)(e_i - e_j)$ exchanges the coordinates x_i and x_j. So W is the image of the group generated by the transpositions, which is S_n, and S_n acts faithfully on E for $n \geq 2$: a permutation fixing every $e_i - e_j$ is the identity. □

Exercise 13.12.13. Show that α-strings have length at most 4: in Theorem 13.9.6(3), $r + q \leq 3$. Find a string of length 4 in G_2.

Solution. Apply Theorem 13.9.6(3) to the bottom $\beta' = \beta - r\alpha$ of the string, which is the same string; for β' one has $r' = 0$ and $q' = r + q$, so $\langle \beta', \alpha \rangle = -(r + q)$. As $\beta' \neq \pm\alpha$ (β is not a multiple of α), Lemma 13.10.2 gives $|\langle \beta', \alpha \rangle| \leq 3$. In G_2, for the short root $\alpha = \varepsilon_1 - \varepsilon_2$ and the long root $\beta = -(2\varepsilon_1 - \varepsilon_2 - \varepsilon_3)$, the vectors β, $\beta + \alpha = \varepsilon_3 - \varepsilon_1$, $\beta + 2\alpha = \varepsilon_3 - \varepsilon_2$ and $\beta + 3\alpha = -(2\varepsilon_2 - \varepsilon_1 - \varepsilon_3)$ are roots, while $\beta - \alpha$ and $\beta + 4\alpha$ are not; accordingly $\langle \beta, \alpha \rangle = 2(-3)/2 = -3 = r - q$. □

Exercise 13.12.14. Using the Weyl dimension formula (Remark 13.11.3), check that $\dim V(\omega_1) = 3$ and $\dim V(\omega_1 + \omega_2) = 8$ for $\mathfrak{sl}_3$, in agreement with Example 13.11.4, and compute $\dim V(2\omega_1)$. Identify $V(2\omega_1)$ with $S^2(\mathbb{C}^3)$.

Solution. All roots of A_2 have the same length; normalise $(\alpha_i, \alpha_i) = 2$, so $(\alpha_1, \alpha_2) = -1$, and $(\omega_i, \alpha_j) = \delta_{ij}$. By Lemma 13.10.6, $(\rho, \alpha_i) = 1$, so $\rho = \omega_1 + \omega_2$ and $(\rho, \alpha_1 + \alpha_2) = 2$. For $\lambda = a\omega_1 + b\omega_2$, the formula gives

$$\dim V(\lambda) = \frac{(a+1)}{1} \cdot \frac{(b+1)}{1} \cdot \frac{(a+b+2)}{2},$$

which is 3 for $(a, b) = (1, 0)$, 8 for $(1, 1)$, and 6 for $(2, 0)$. The weights of $S^2(\mathbb{C}^3)$ are the $\varepsilon_i + \varepsilon_j$, $i \leq j$, with e_1^2 of weight $2\varepsilon_1 = 2\omega_1$ killed by the upper triangular matrices; its dimension is 6. The subrepresentation W generated by e_1^2 has $W_{2\omega_1} = \mathbb{C}e_1^2$, as in the proof of Theorem 13.11.2(3); in a decomposition $W = W_1 \oplus W_2$ into subrepresentations this line lies in one summand, which then contains e_1^2 and is all of W. So W is indecomposable, hence irreducible by Weyl's theorem, of highest weight $2\omega_1$, and of dimension 6; so $W = S^2(\mathbb{C}^3)$. □

Exercise 13.12.15. Show that Theorem 13.7.11 fails for the abelian Lie algebra k^2 and for the Heisenberg algebra $\mathfrak{n}_3$ (Example 13.5.3(3)): exhibit derivations that are not inner.

Solution. For an abelian Lie algebra every linear map is a derivation, while all inner derivations are 0. For $\mathfrak{n}_3$ with $[E_{12}, E_{23}] = E_{13}$, the linear map δ with $\delta E_{12} = E_{12}$, $\delta E_{23} = 0$, $\delta E_{13} = E_{13}$ is a derivation: on the only nonzero bracket, $\delta[E_{12}, E_{23}] = E_{13} = [\delta E_{12}, E_{23}] + [E_{12}, \delta E_{23}]$, and the brackets involving E_{13} vanish on both sides. An inner derivation $\operatorname{ad} x$ maps $\mathfrak{n}_3$ into $[\mathfrak{n}_3, \mathfrak{n}_3] = \mathbb{C}E_{13}$, while $\delta E_{12} = E_{12}$; so δ is not inner. □

Chapter 14

Commutative Algebra

14.1 Introduction

Commutative algebra is the local theory of algebraic geometry. This chapter develops the tools used in Part VIII and in the local theory of analytic functions (Chapter 31): localisation, Nakayama's lemma, Noetherian and Artinian rings, integral extensions and Noether normalisation, the Nullstellensatz, primary decomposition, dimension theory, regular local rings and Dedekind domains, completions, and Kähler differentials.

References are [AM69], [Mat86] and [Eis95].

Prerequisites. Chapter 8 (Rings and Modules), Chapter 9 (Fields and Galois Theory) and Chapter 11 (Linear Algebra).

On the way to the Hodge conjecture. Needed for algebraic geometry: radicals, localisation, Nakayama's lemma, Noetherian rings, integral extensions, the Nullstellensatz, dimension theory and regular local rings. Primary decomposition and completions can be postponed; Kähler differentials (Section 14.12) are used for sheaves of differentials.

In accordance with Notation 1.7.4, from now on all rings are commutative with 1.

14.2 Prime ideals and radicals

Definition 14.2.1. The *spectrum* $\operatorname{Spec} R$ is the set of prime ideals of R. For an ideal I let $V(I) = \{\mathfrak{p} \in \operatorname{Spec} R : I \subseteq \mathfrak{p}\}$, and for $f \in R$ let $D(f) = \{\mathfrak{p} : f \notin \mathfrak{p}\}$. The *nilradical* of R is the set of nilpotent elements, the *Jacobson radical* $J(R)$ is the intersection of all maximal ideals, and the *radical* of an ideal is $\sqrt{I} = \{f : f^n \in I \text{ for some } n\}$.

Proposition 14.2.2. *1. The nilradical is the intersection of all prime ideals, and $\sqrt{I}$ is the intersection of all primes containing I.*

2. *More precisely, if $S \subseteq R$ is closed under multiplication, $1 \in S$, and I is an ideal with $I \cap S = \emptyset$, then there is a prime $\mathfrak{p} \supseteq I$ with $\mathfrak{p} \cap S = \emptyset$.*

3. *$x \in J(R)$ if and only if $1 - xy$ is a unit for all $y \in R$.*

Proof. (2) The set of ideals containing I and disjoint from S is nonempty and closed under unions of chains, so it has a maximal element $\mathfrak{p}$ by Zorn's lemma. If $a, b \notin \mathfrak{p}$, then $\mathfrak{p} + (a)$ and $\mathfrak{p} + (b)$ meet S, say $s = p_1 + ra$ and $t = p_2 + r'b$; then $st \in \mathfrak{p} + (ab)$ lies in S, so $ab \notin \mathfrak{p}$. Also $1 \in S$, so $\mathfrak{p} \neq R$. (1) A nilpotent element lies in every prime. If f is not nilpotent, apply (2) with $S = \{f^n\}$ and $I = 0$. For $\sqrt{I}$, apply this to R/I. (3) If $x \in J(R)$ and $1 - xy$ is not a unit, it lies in a maximal ideal $\mathfrak{m}$ (Theorem 8.4.3), which also contains xy, hence 1. Conversely if

$x \notin \mathfrak{m}$ for a maximal $\mathfrak{m}$, then $\mathfrak{m} + (x) = R$, so $1 = u + xy$ with $u \in \mathfrak{m}$, and $1 - xy = u$ is not a unit. □

Lemma 14.2.3 (Prime avoidance)**.** *If an ideal I is contained in the union of prime ideals $\mathfrak{p}_1, \dots, \mathfrak{p}_n$, then $I \subseteq \mathfrak{p}_i$ for some i.*

Proof. By induction on n; suppose $I \not\subseteq \bigcup_{j \neq i} \mathfrak{p}_j$ for each i (otherwise use induction), and choose $x_i \in I$ with $x_i \notin \mathfrak{p}_j$ for $j \neq i$. Then $x_i \in \mathfrak{p}_i$ for all i. The element $y = x_1 + x_2 \cdots x_n$ lies in I but in no $\mathfrak{p}_i$: for $i = 1$, $x_1 \in \mathfrak{p}_1$ and $x_2 \cdots x_n \notin \mathfrak{p}_1$; for $i \geq 2$, $x_1 \notin \mathfrak{p}_i$ while $x_2 \cdots x_n \in \mathfrak{p}_i$. This contradicts $I \subseteq \mathfrak{p}_1 \cup \cdots \cup \mathfrak{p}_n$. □

14.3 Localisation

Definition 14.3.1. A subset $S \subseteq R$ is *multiplicative* if $1 \in S$ and $st \in S$ for $s, t \in S$. For an R-module M, the *localisation* $S^{-1}M$ is the set of equivalence classes m/s of pairs $(m, s) \in M \times S$ under $(m, s) \sim (m', s') \iff t(s'm - sm') = 0$ for some $t \in S$, with $m/s + m'/s' = (s'm + sm')/ss'$. For $M = R$ it is a ring with $(r/s)(r'/s') = rr'/ss'$, and $S^{-1}M$ is an $S^{-1}R$-module. For $f \in R$ we write R_f for $S^{-1}R$ with $S = \{f^n\}$, and for a prime $\mathfrak{p}$ we write $R_\mathfrak{p}$, $M_\mathfrak{p}$ for $S = R \setminus \mathfrak{p}$. A ring is *local* if it has exactly one maximal ideal.

Proposition 14.3.2.
1. *$\sim$ is an equivalence relation and the operations are well defined. The map $R \to S^{-1}R$, $r \mapsto r/1$, is a ring homomorphism sending S to units, and every homomorphism $\varphi\colon R \to B$ sending S to units factors uniquely through it.*
2. *If $M' \to M \to M''$ is exact, so is $S^{-1}M' \to S^{-1}M \to S^{-1}M''$. There is a natural isomorphism $S^{-1}R \otimes_R M \cong S^{-1}M$; hence $S^{-1}R$ is a flat R-module.*
3. *The primes of $S^{-1}R$ are the $S^{-1}\mathfrak{p}$ for primes $\mathfrak{p}$ of R with $\mathfrak{p} \cap S = \emptyset$, and this is an inclusion-preserving bijection with inverse $\mathfrak{q} \mapsto$ its preimage in R. In particular $R_\mathfrak{p}$ is local with maximal ideal $\mathfrak{p}R_\mathfrak{p}$.*
4. *A ring is local if and only if its nonunits form an ideal.*

Proof. (1) Transitivity: from $t(s'm - sm') = 0$ and $t'(s''m' - s'm'') = 0$, multiplying by $t's''$ and ts and adding gives $tt's'(s''m - sm'') = 0$. The other verifications are similar. Given φ, the map $r/s \mapsto \varphi(r)\varphi(s)^{-1}$ is well defined since $t(s'r - sr') = 0$ implies $\varphi(s'r) = \varphi(sr')$, and it is forced. (2) Let $f\colon M' \to M$, $g\colon M \to M''$ with $\operatorname{im} f = \ker g$. If $g(m)/s = 0$, then $tg(m) = 0$ for some t, so $tm = f(m')$ and $m/s = f(m')/ts$. The map $S^{-1}R \times M \to S^{-1}M$, $(r/s, m) \mapsto rm/s$, is bilinear, and $m/s \mapsto (1/s) \otimes m$ is a well-defined inverse of the induced map: if $t(s'm - sm') = 0$ then $(1/s) \otimes m = (1/tss') \otimes ts'm = (1/tss') \otimes tsm' = (1/s') \otimes m'$. So $S^{-1}R \otimes -$ is exact, that is, $S^{-1}R$ is flat. (3) If $\mathfrak{q}$ is a prime of $S^{-1}R$, its preimage $\mathfrak{p}$ is prime and disjoint from S, and $\mathfrak{q} = S^{-1}\mathfrak{p}$ since $r/s \in \mathfrak{q}$ iff $r/1 \in \mathfrak{q}$. Conversely, for $\mathfrak{p}$ disjoint from S, $S^{-1}\mathfrak{p}$ is a proper ideal, it is prime because $(r/s)(r'/s') \in S^{-1}\mathfrak{p}$ gives $trr' \in \mathfrak{p}$ for some $t \in S$, and its preimage is $\mathfrak{p}$ by the same argument. For $R_\mathfrak{p}$, the primes correspond to primes contained in $\mathfrak{p}$. (4) If the nonunits form an ideal, it is the unique maximal ideal. If R is local with maximal ideal $\mathfrak{m}$, every nonunit lies in a maximal ideal, hence in $\mathfrak{m}$. □

Proposition 14.3.3. *For an R-module M the following are equivalent: $M = 0$; $M_\mathfrak{p} = 0$ for all primes $\mathfrak{p}$; $M_\mathfrak{m} = 0$ for all maximal ideals $\mathfrak{m}$. A homomorphism $M \to N$ is injective (surjective) if and only if all $M_\mathfrak{m} \to N_\mathfrak{m}$ are.*

Proof. If $x \in M$ is nonzero, its annihilator is a proper ideal, contained in a maximal ideal $\mathfrak{m}$, and then $x/1 \neq 0$ in $M_\mathfrak{m}$. The second statement follows by applying the first to kernels and cokernels, which commute with localisation by Proposition 14.3.2(2). □

Example 14.3.4. $\mathbb{Z}_{(p)}$ is the ring of rationals whose denominators are prime to p, a local ring with maximal ideal $p\mathbb{Z}_{(p)}$; $\mathbb{Z}_{(0)} = \mathbb{Q}$; and the localisation of $\mathbb{Z}$ at $f = p$ is $\mathbb{Z}[1/p]$, the ring of rationals whose denominators are powers of p (we avoid the notation $\mathbb{Z}_p$ for it, which is reserved for the p-adic integers). Localisation can kill elements: in $(\mathbb{Z}/6\mathbb{Z})_{(2)}$ the element 3 is a unit and $2 \cdot 3 = 0$, so $2/1 = 0$ and $(\mathbb{Z}/6\mathbb{Z})_{(2)} \cong \mathbb{Z}/2\mathbb{Z}$. If f is nilpotent, $R_f = 0$.

14.4 Nakayama's lemma

Lemma 14.4.1 (Determinant trick)**.** *Let M be an R-module generated by n elements, I an ideal and $\varphi\colon M \to M$ an R-linear map with $\varphi(M) \subseteq IM$. Then $\varphi^n + a_1\varphi^{n-1} + \cdots + a_n = 0$ for some $a_i \in I$.*

Proof. Let $x_1, \dots, x_n$ generate M and write $\varphi(x_i) = \sum_j a_{ij}x_j$ with $a_{ij} \in I$. View M as a module over the commutative ring $R[\varphi]$ of endomorphisms. The matrix $T = \varphi I - (a_{ij})$ over $R[\varphi]$ kills the column vector (x_j), so by Proposition 11.5.3(4) $\det(T)x_j = \operatorname{adj}(T)T(x) = 0$ for all j, that is, $\det T = 0$ on M. Expanding the determinant gives the claim. □

Theorem 14.4.2 (Nakayama's lemma)**.** *Let M be a finitely generated R-module and I an ideal with $IM = M$. Then there is $a \in 1 + I$ with $aM = 0$. If $I \subseteq J(R)$, then $M = 0$.*

Proof. Apply Lemma 14.4.1 to $\varphi = \mathrm{id}$: $a = 1 + a_1 + \cdots + a_n$ kills M. If $I \subseteq J(R)$, a is a unit by Proposition 14.2.2(3). □

Corollary 14.4.3. *Let $(R, \mathfrak{m}, k)$ be a local ring and M a finitely generated module. Elements $x_1, \dots, x_n \in M$ generate M if and only if their images generate the k-vector space $M/\mathfrak{m}M$. Every minimal generating set has $\dim_k M/\mathfrak{m}M$ elements.*

Proof. Let N be the submodule generated by the x_i. If their images generate $M/\mathfrak{m}M$ then $M = N + \mathfrak{m}M$, so $\mathfrak{m}(M/N) = M/N$ and $M/N = 0$ by Theorem 14.4.2. The last statement follows because a generating set of M maps to a spanning set of $M/\mathfrak{m}M$, and a minimal one to a basis. □

14.5 Noetherian and Artinian rings

Definition 14.5.1. A module is *Noetherian* if every increasing chain of submodules is eventually constant, and *Artinian* if every decreasing chain is. A ring is Noetherian (Artinian) if it is so as a module over itself.

Proposition 14.5.2.

1. *M is Noetherian if and only if every submodule is finitely generated, if and only if every nonempty set of submodules has a maximal element.*
2. *If $0 \to M' \to M \to M'' \to 0$ is exact, then M is Noetherian (Artinian) if and only if M' and M'' are.*
3. *Over a Noetherian ring, finitely generated modules are Noetherian; quotients and localisations of Noetherian rings are Noetherian.*

Proof. (1) If N is not finitely generated, choose $x_1, x_2, \dots \in N$ with $x_{n+1} \notin (x_1, \dots, x_n)$, a strictly increasing chain (using dependent choice). If every submodule is finitely generated, the union of a chain is generated by finitely many elements, which lie in one member. A nonempty set without maximal element contains a strictly increasing chain, and conversely a strictly increasing chain has no maximal element. (2) A chain in M gives chains in M' and M''; if both stabilise, so does the original, because $N_1 \subseteq N_2$ with $N_1 \cap M' = N_2 \cap M'$ and equal images in M'' implies $N_1 = N_2$. The converse is clear. (3) R^n is Noetherian by (2) and

induction, and finitely generated modules are its quotients. Ideals of $S^{-1}R$ are of the form $S^{-1}I$ (by the argument of Proposition 14.3.2(3)), so they are finitely generated. □

Theorem 14.5.3 (Hilbert's basis theorem)**.** *If R is Noetherian, so is $R[x]$. Consequently every finitely generated R-algebra is Noetherian; in particular $k[x_1, \dots, x_n]$ and $\mathbb{Z}[x_1, \dots, x_n]$ are Noetherian.*

Proof. Let $I \subseteq R[x]$ be an ideal and $L_d \subseteq R$ the set of leading coefficients of elements of I of degree d, together with 0. These are ideals with $L_d \subseteq L_{d+1}$ (multiply by x), so $L_d = L_{d_0}$ for $d \geq d_0$. For each $d \leq d_0$ choose finitely many $f_{d,j} \in I$ of degree d whose leading coefficients generate L_d. Let I' be the ideal they generate. If $f \in I$ has degree d, some combination $g = \sum_j c_j x^{d-\min(d,d_0)} f_{\min(d,d_0),j}$ has the same degree and leading coefficient, so $f - g \in I$ has smaller degree; by induction on the degree $f \in I'$. So $I = I'$. The last statement follows from quotients (Proposition 14.5.2). □

Counterexample 14.5.4. The polynomial ring $k[x_1, x_2, \dots]$ in infinitely many variables is not Noetherian: $(x_1) \subsetneq (x_1, x_2) \subsetneq \cdots$. It is a subring of its fraction field, which is Noetherian; so subrings of Noetherian rings need not be Noetherian.

Lemma 14.5.5. *Let R be a ring and $\mathfrak{m}_1, \dots, \mathfrak{m}_n$ maximal ideals (not necessarily distinct) with $\mathfrak{m}_1 \cdots \mathfrak{m}_n = 0$. Then R is Noetherian if and only if it is Artinian.*

Proof. Consider the chain $R \supseteq \mathfrak{m}_1 \supseteq \mathfrak{m}_1\mathfrak{m}_2 \supseteq \cdots \supseteq \mathfrak{m}_1 \cdots \mathfrak{m}_n = 0$. Each quotient is a vector space over the field $R/\mathfrak{m}_i$, and for a vector space the ascending and the descending chain conditions are both equivalent to finite dimension. By Proposition 14.5.2(2) applied along the chain, R satisfies ACC iff all quotients are finite-dimensional iff R satisfies DCC. □

Theorem 14.5.6. *An Artinian ring R is Noetherian, every prime ideal of R is maximal, R has finitely many maximal ideals, its nilradical is nilpotent, and R is a finite product of local Artinian rings. (For the converse see Corollary 14.8.5.)*

Proof. Let R be Artinian. If $\mathfrak{p}$ is prime, $R/\mathfrak{p}$ is an Artinian domain; for $x \neq 0$ the chain $(x) \supseteq (x^2) \supseteq \cdots$ stabilises, $x^n = x^{n+1}y$, so $xy = 1$; hence $\mathfrak{p}$ is maximal. Among finite intersections of maximal ideals choose a minimal one, $\mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n$; every maximal $\mathfrak{m}$ contains it, hence contains $\mathfrak{m}_1 \cdots \mathfrak{m}_n$ and so some $\mathfrak{m}_i$, and $\mathfrak{m} = \mathfrak{m}_i$. The nilradical $N = \mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n$ satisfies $N^k = N^{k+1} = \cdots =: I$ for some k. If $I \neq 0$, choose an ideal J minimal with $IJ \neq 0$; there is $x \in J$ with $xI \neq 0$, so $J = (x)$ by minimality, and $(xI)I = xI \neq 0$ with $xI \subseteq (x)$ gives $xI = (x)$, so $x = xy$ with $y \in I$, hence $x = xy^m = 0$ as y is nilpotent; contradiction. So N is nilpotent, $(\mathfrak{m}_1 \cdots \mathfrak{m}_n)^k \subseteq N^k = 0$, and R is Noetherian by Lemma 14.5.5.

Finally, the ideals $\mathfrak{m}_i^k$ are pairwise comaximal and their product is 0, so $R \cong \prod_i R/\mathfrak{m}_i^k$ by Theorem 8.3.3, and $R/\mathfrak{m}_i^k$ is local with maximal ideal $\mathfrak{m}_i/\mathfrak{m}_i^k$. □

14.6 Integral extensions

Definition 14.6.1. Let $A \subseteq B$ be rings. An element $b \in B$ is *integral* over A if it is a root of a monic polynomial with coefficients in A. B is *integral* over A if all its elements are, and *finite* over A if it is a finitely generated A-module. The *integral closure* of A in B is the set of elements integral over A. A domain is *normal* (or integrally closed) if it equals its integral closure in its fraction field.

Proposition 14.6.2.

1. *b is integral over A if and only if $A[b]$ is a finite A-module, if and only if b lies in a subring $C \subseteq B$ that is a finite A-module.*
2. *The integral closure of A in B is a subring. If $A \subseteq B \subseteq C$ with C integral over B and B integral over A, then C is integral over A.*

3. *If $A \subseteq B$ are domains and B is integral over A, then B is a field if and only if A is.*

4. *A unique factorisation domain is normal.*

Proof. (1) A monic equation of degree n shows that $1, b, \dots, b^{n-1}$ generate $A[b]$. If $b \in C$ with C finite, apply Lemma 14.4.1 to multiplication by b on C with $I = A$; the resulting polynomial kills $1 \in C$, so it vanishes at b. (2) If b, b' are integral, $A[b, b']$ is finite over A, so $b \pm b'$ and bb' are integral by (1). If $c \in C$ satisfies a monic equation with coefficients $b_1, \dots, b_n \in B$, then $A[b_1, \dots, b_n, c]$ is finite over A by the tower of finite extensions, so c is integral over A. (3) If A is a field and $0 \neq b \in B$ satisfies $b^n + a_1 b^{n-1} + \cdots + a_n = 0$ with n minimal, then $a_n \neq 0$ (as B is a domain), and $b^{-1} = -a_n^{-1}(b^{n-1} + \cdots + a_{n-1}) \in B$. If B is a field and $0 \neq a \in A$, then $a^{-1} \in B$ is integral over A: $a^{-m} + c_1 a^{-m+1} + \cdots + c_m = 0$, so $a^{-1} = -(c_1 + c_2 a + \cdots + c_m a^{m-1}) \in A$. (4) If $x = r/s$ in lowest terms satisfies a monic equation of degree n, then $r^n = -s(a_1 r^{n-1} + \cdots + a_n s^{n-1})$, so every prime factor of s divides r; hence s is a unit. □

Theorem 14.6.3 (Lying over and going up)**.** *Let $A \subseteq B$ be an integral extension and $\mathfrak{p}$ a prime of A.*

1. *There is a prime $\mathfrak{q}$ of B with $\mathfrak{q} \cap A = \mathfrak{p}$.*

2. *If $\mathfrak{q} \subseteq \mathfrak{q}'$ are primes of B with $\mathfrak{q} \cap A = \mathfrak{q}' \cap A$, then $\mathfrak{q} = \mathfrak{q}'$ (incomparability). A prime $\mathfrak{q}$ is maximal if and only if $\mathfrak{q} \cap A$ is maximal.*

3. *If $\mathfrak{p} \subseteq \mathfrak{p}'$ are primes of A and $\mathfrak{q} \cap A = \mathfrak{p}$, there is $\mathfrak{q}' \supseteq \mathfrak{q}$ with $\mathfrak{q}' \cap A = \mathfrak{p}'$ (going up).*

Proof. For a prime $\mathfrak{q}$ of B over $\mathfrak{p}$, the extension $A/\mathfrak{p} \subseteq B/\mathfrak{q}$ is integral, so by Proposition 14.6.2(3) $\mathfrak{q}$ is maximal iff $\mathfrak{p}$ is. This gives the second part of (2).

(1) Let $S = A \setminus \mathfrak{p}$. Then $A_{\mathfrak{p}} \subseteq S^{-1}B$ is integral and $S^{-1}B \neq 0$. Let $\mathfrak{n}$ be a maximal ideal of $S^{-1}B$. Then $\mathfrak{n} \cap A_{\mathfrak{p}}$ is maximal by the first remark, hence equals $\mathfrak{p}A_{\mathfrak{p}}$, and the preimage $\mathfrak{q}$ of $\mathfrak{n}$ in B satisfies $\mathfrak{q} \cap A = \mathfrak{p}$. (2) Localising at $S = A \setminus \mathfrak{p}$ as in (1), $S^{-1}\mathfrak{q} \subseteq S^{-1}\mathfrak{q}'$ both lie over the maximal ideal $\mathfrak{p}A_{\mathfrak{p}}$, hence are maximal, hence equal, and so $\mathfrak{q} = \mathfrak{q}'$. (3) Apply (1) to the integral extension $A/\mathfrak{p} \subseteq B/\mathfrak{q}$ and the prime $\mathfrak{p}'/\mathfrak{p}$. □

Remark 14.6.4. If moreover A is a normal domain and B is a domain, the *going down* theorem holds: given $\mathfrak{p}' \subseteq \mathfrak{p}$ and $\mathfrak{q}$ over $\mathfrak{p}$, there is $\mathfrak{q}' \subseteq \mathfrak{q}$ over $\mathfrak{p}'$ [AM69, Theorem 5.16].

Theorem 14.6.5 (Noether normalisation)**.** *Let A be a finitely generated algebra over a field k. There are elements $y_1, \dots, y_d \in A$, algebraically independent over k, such that A is finite over $k[y_1, \dots, y_d]$.*

Proof. By induction on the number n of generators $x_1, \dots, x_n$. If they are algebraically independent, take $y_i = x_i$. Otherwise let $F \neq 0$ be a polynomial with $F(x_1, \dots, x_n) = 0$, and let r be larger than all exponents occurring in F. Put $z_i = x_i - x_n^{r^i}$ for $i < n$. Substituting $x_i = z_i + x_n^{r^i}$, a monomial $c\, x_1^{a_1} \cdots x_n^{a_n}$ of F becomes $c\, x_n^{a_n + a_1 r + \cdots + a_{n-1} r^{n-1}}$ plus terms of lower degree in x_n with coefficients in $k[z_1, \dots, z_{n-1}]$. The exponents $a_n + a_1 r + \cdots$ of distinct monomials are distinct (base r expansions), so exactly one monomial produces the highest power of x_n. Dividing by its coefficient, x_n satisfies a monic equation over $k[z_1, \dots, z_{n-1}]$. So $A = k[z_1, \dots, z_{n-1}][x_n]$ is finite over $k[z_1, \dots, z_{n-1}]$, which by induction is finite over a polynomial ring $k[y_1, \dots, y_d]$; conclude with Proposition 14.6.2(2). □

14.7 The Nullstellensatz

Theorem 14.7.1 (Zariski's lemma)**.** *Let k be a field and L a field that is finitely generated as a k-algebra. Then L is a finite extension of k. Consequently, for every finitely generated k-algebra A and maximal ideal $\mathfrak{m}$, $A/\mathfrak{m}$ is finite over k.*

Proof. By Theorem 14.6.5, L is finite over some $k[y_1, \dots, y_d]$, which is then a field by Proposition 14.6.2(3). A polynomial ring in $d \geq 1$ variables is not a field, so $d = 0$. □

Theorem 14.7.2 (Hilbert's Nullstellensatz)**.** *Let k be algebraically closed. For $I \subseteq k[x_1, \dots, x_n]$ let $Z(I) = \{a \in k^n : f(a) = 0 \text{ for all } f \in I\}$.*

1. *The maximal ideals of $k[x_1, \dots, x_n]$ are the ideals $(x_1 - a_1, \dots, x_n - a_n)$, $a \in k^n$.*
2. *If $I \neq (1)$ then $Z(I) \neq \emptyset$.*
3. *If f vanishes on $Z(I)$, then $f \in \sqrt{I}$.*

Proof. (1) The ideal $(x_1 - a_1, \dots, x_n - a_n)$ is the kernel of evaluation at a, which is surjective onto k, so it is maximal. If $\mathfrak{m}$ is maximal, $k[x]/\mathfrak{m}$ is a finite extension of k by Theorem 14.7.1, hence equals k; so $x_i \equiv a_i$ modulo $\mathfrak{m}$ for some $a_i \in k$, and $\mathfrak{m}$ contains, hence equals, $(x - a)$. (2) A proper ideal lies in a maximal ideal $(x - a)$, and then $a \in Z(I)$. (3) (Rabinowitsch) We may assume $f \neq 0$. In $k[x_1, \dots, x_n, y]$ the ideal $J = Ik[x, y] + (1 - yf)$ has no zeros, since at a zero (a, b) we would have $a \in Z(I)$, so $f(a) = 0$ and $1 - bf(a) = 1$. By (2), $1 = \sum_i g_i h_i + g(1 - yf)$ with $h_i \in I$. Substituting $y = 1/f$ in $k(x_1, \dots, x_n)$ and multiplying by a high power f^N gives $f^N = \sum_i g_i' h_i \in I$. □

Counterexample 14.7.3. Algebraic closedness is needed: over $\mathbb{R}$, the ideal $(x^2 + 1) \subsetneq \mathbb{R}[x]$ is maximal but has no zeros in $\mathbb{R}$, and $\mathbb{R}[x]/(x^2 + 1) \cong \mathbb{C}$ is a finite extension of $\mathbb{R}$ different from $\mathbb{R}$.

Corollary 14.7.4. *In a finitely generated algebra A over a field, the nilradical equals the Jacobson radical.*

Proof. Let $f \in A$ be non-nilpotent. Then $A_f \neq 0$ has a maximal ideal $\mathfrak{n}$, and $A_f \cong A[t]/(tf - 1)$ is finitely generated, so $A_f/\mathfrak{n}$ is a finite field extension of k. The preimage $\mathfrak{m}$ of $\mathfrak{n}$ in A does not contain f, and $k \subseteq A/\mathfrak{m} \subseteq A_f/\mathfrak{n}$, so $A/\mathfrak{m}$ is a domain finite-dimensional over k, hence a field (Proposition 14.6.2(3)). So $f \notin J(A)$. □

14.8 Primary decomposition

In this section R is Noetherian.

Definition 14.8.1. Let M be an R-module. A prime $\mathfrak{p}$ is *associated* to M if $\mathfrak{p} = \operatorname{Ann}(x)$ for some $x \in M$; we write $\operatorname{Ass}(M)$. An ideal $\mathfrak{q} \neq R$ is *primary* if $xy \in \mathfrak{q}$ and $x \notin \mathfrak{q}$ imply $y^n \in \mathfrak{q}$ for some n. Then $\mathfrak{p} = \sqrt{\mathfrak{q}}$ is prime, and $\mathfrak{q}$ is called $\mathfrak{p}$-primary.

Proposition 14.8.2. *Let M be a finitely generated R-module.*

1. *Every maximal element of $\{\operatorname{Ann}(x) : 0 \neq x \in M\}$ is a prime ideal; so $M \neq 0$ implies $\operatorname{Ass}(M) \neq \emptyset$.*
2. *The set of zero divisors on M is $\bigcup_{\mathfrak{p} \in \operatorname{Ass}(M)} \mathfrak{p}$.*
3. *There is a chain $0 = M_0 \subseteq \cdots \subseteq M_n = M$ with $M_i/M_{i-1} \cong R/\mathfrak{p}_i$ for primes $\mathfrak{p}_i$, and $\operatorname{Ass}(M) \subseteq \{\mathfrak{p}_1, \dots, \mathfrak{p}_n\}$; in particular $\operatorname{Ass}(M)$ is finite.*

Proof. (1) Let $I = \operatorname{Ann}(x)$ be maximal and $ab \in I$ with $b \notin I$. Then $bx \neq 0$ and $\operatorname{Ann}(bx) \supseteq I + (a)$, so $a \in I$ by maximality. Maximal elements exist by Proposition 14.5.2(1). (2) Elements of associated primes are clearly zero divisors. If $ax = 0$ with $x \neq 0$, choose $z \in Rx$, $z \neq 0$, with $\operatorname{Ann}(z)$ maximal among the annihilators of nonzero elements of Rx. The argument of (1),

applied inside Rx, shows that $\operatorname{Ann}(z)$ is prime, and it contains $\operatorname{Ann}(x) \ni a$. (3) By (1), choose $M_1 = Rx_1 \cong R/\mathfrak{p}_1$, then apply (1) to M/M_1, and so on; the chain stops since M is Noetherian. If $0 \to M' \to M \to M'' \to 0$ is exact then $\operatorname{Ass}(M) \subseteq \operatorname{Ass}(M') \cup \operatorname{Ass}(M'')$: if $\operatorname{Ann}(x) = \mathfrak{p}$ and $Rx \cap M' \neq 0$, a nonzero $yx \in M'$ has annihilator $\mathfrak{p}$ (as $R/\mathfrak{p}$ is a domain); otherwise Rx maps isomorphically into M''. Finally $\operatorname{Ass}(R/\mathfrak{p}) = \{\mathfrak{p}\}$ since $R/\mathfrak{p}$ is a domain. □

Theorem 14.8.3 (Lasker–Noether)**.** *Every ideal $I \neq R$ of a Noetherian ring is a finite intersection $I = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_r$ of primary ideals. One can choose the decomposition with the primes $\sqrt{\mathfrak{q}_i}$ distinct and no $\mathfrak{q}_i$ superfluous; the set of these primes is then $\operatorname{Ass}(R/I)$, independent of the decomposition. The minimal elements of $\operatorname{Ass}(R/I)$ are the minimal primes containing I.*

Proof. Call I *irreducible* if $I = J \cap J'$ implies $I = J$ or $I = J'$. If some ideal is not a finite intersection of irreducible ideals, a maximal such ideal is reducible, a contradiction; so every ideal is a finite intersection of irreducibles. An irreducible ideal I is primary: passing to R/I, suppose $xy = 0$ with $x \neq 0$. The chain $\operatorname{Ann}(y) \subseteq \operatorname{Ann}(y^2) \subseteq \cdots$ stabilises at n; then $(x) \cap (y^n) = 0$ (if $ax = by^n$ then $axy = 0 = by^{n+1}$, so $by^n = 0$), and irreducibility of 0 gives $y^n = 0$.

If $\mathfrak{q}$ is $\mathfrak{p}$-primary, then $\operatorname{Ass}(R/\mathfrak{q}) = \{\mathfrak{p}\}$: if $\operatorname{Ann}(\bar{x}) = \mathfrak{p}'$ with $x \notin \mathfrak{q}$, then $\mathfrak{p}'x \subseteq \mathfrak{q}$ gives $\mathfrak{p}' \subseteq \mathfrak{p}$, and every $a \in \mathfrak{p}$ has $a^n\bar{x} = 0$, so $a \in \mathfrak{p}'$. A finite intersection of $\mathfrak{p}$-primary ideals is $\mathfrak{p}$-primary, so we may merge components with the same prime, and delete superfluous ones. Then $R/I \hookrightarrow \bigoplus_i R/\mathfrak{q}_i$ gives $\operatorname{Ass}(R/I) \subseteq \{\mathfrak{p}_i\}$, by the argument in Proposition 14.8.2(3). Conversely, if $\mathfrak{q}_i$ is not superfluous, choose $x \in \bigcap_{j\neq i} \mathfrak{q}_j \setminus \mathfrak{q}_i$; then $\bar{x} \in R/I$ generates a submodule isomorphic to a submodule of $R/\mathfrak{q}_i$, whose associated primes are $\{\mathfrak{p}_i\}$, so $\mathfrak{p}_i \in \operatorname{Ass}(R/I)$. For the last statement, a prime contains $I = \bigcap \mathfrak{q}_i$ iff it contains some $\mathfrak{q}_i$ iff it contains some $\mathfrak{p}_i$. □

Example 14.8.4. In $k[x, y]$, $(x^2, xy) = (x) \cap (x^2, y)$, where (x) is prime and (x^2, y) is (x, y)-primary. The associated primes are (x) and the *embedded* prime $(x, y) \supsetneq (x)$. Geometrically, the ideal defines the line $x = 0$ with an extra infinitesimal structure at the origin.

Corollary 14.8.5. *A Noetherian ring in which every prime ideal is maximal is Artinian.*

Proof. By Theorem 14.8.3 applied to $I = 0$, the ring has finitely many minimal primes; since all primes are maximal, these are all the primes, say $\mathfrak{m}_1, \ldots, \mathfrak{m}_n$. Their intersection is the nilradical (Proposition 14.2.2), which is finitely generated, hence nilpotent: $(\mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n)^k = 0$. Then $(\mathfrak{m}_1 \cdots \mathfrak{m}_n)^k = 0$, and the ring is Artinian by Lemma 14.5.5. □

14.9 Dimension theory

Definition 14.9.1. The *Krull dimension* $\dim R$ is the supremum of the lengths n of chains of primes $\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_n$. The *height* of a prime is $\operatorname{ht}\mathfrak{p} = \dim R_{\mathfrak{p}}$, the supremum of lengths of chains ending at $\mathfrak{p}$.

Proposition 14.9.2. *If B is integral over A, then $\dim B = \dim A$.*

Proof. A chain of primes of B contracts to a chain in A with strict inclusions by incomparability, and a chain in A lifts by lying over and going up (Theorem 14.6.3). □

Theorem 14.9.3. *Let A be a finitely generated k-algebra that is a domain. Then $\dim A = \operatorname{trdeg}_k \operatorname{Frac}(A)$. In particular $\dim k[x_1, \ldots, x_n] = n$.*

Proof. Let $t = \operatorname{trdeg}_k \operatorname{Frac}(A)$. By Theorem 14.6.5, A is finite over a polynomial ring $k[y_1, \ldots, y_d]$; then $\operatorname{Frac}(A)$ is algebraic over $k(y_1, \ldots, y_d)$, so $d = t$, and $\dim A = \dim k[y_1, \ldots, y_t]$ by Proposition 14.9.2. The chain $0 \subsetneq (y_1) \subsetneq (y_1, y_2) \subsetneq \cdots \subsetneq (y_1, \ldots, y_t)$ consists of primes

(the quotients are polynomial rings), so $\dim \geq t$. We show $\dim A \leq t$ for all such A by induction on t; by the above we may assume $A = k[y_1, \ldots, y_t]$. Let $0 = \mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_m$ be a chain. The domain $A/\mathfrak{p}_1$ is generated by the images of the y_i, which satisfy a nontrivial polynomial relation (any nonzero element of $\mathfrak{p}_1$), so its fraction field has transcendence degree $< t$ (Theorem 9.10.3). By induction the chain $\mathfrak{p}_1/\mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_m/\mathfrak{p}_1$ has length $m-1 \leq t-1$. □

Lemma 14.9.4. *A Noetherian local ring $(R, \mathfrak{m})$ in which $\mathfrak{m}$ is the only prime is Artinian, and $\mathfrak{m}^n = 0$ for some n.*

Proof. The nilradical is $\mathfrak{m}$ (Proposition 14.2.2), which is finitely generated, so $\mathfrak{m}^n = 0$; apply Lemma 14.5.5. □

Theorem 14.9.5 (Krull's principal ideal theorem)**.** *Let R be Noetherian, $x \in R$, and $\mathfrak{p}$ a prime minimal among primes containing x. Then $\operatorname{ht}\mathfrak{p} \leq 1$. More generally, if $\mathfrak{p}$ is minimal over $(x_1, \ldots, x_r)$, then $\operatorname{ht}\mathfrak{p} \leq r$.*

Proof. Localising at $\mathfrak{p}$ we may assume $(R, \mathfrak{p})$ local with $\mathfrak{p}$ minimal over (x). Let $\mathfrak{q} \subsetneq \mathfrak{p}$ be prime; we show $\operatorname{ht}\mathfrak{q} = 0$. For $n \geq 1$ let $\mathfrak{q}^{(n)} = \mathfrak{q}^n R_\mathfrak{q} \cap R$. The ring $R/(x)$ has $\mathfrak{p}/(x)$ as its only prime, so it is Artinian (Lemma 14.9.4), and the chain $\mathfrak{q}^{(n)} + (x)$ stabilises: for large n, $\mathfrak{q}^{(n)} \subseteq \mathfrak{q}^{(n+1)} + (x)$. For $a \in \mathfrak{q}^{(n)}$ write $a = b + rx$ with $b \in \mathfrak{q}^{(n+1)}$; then $rx \in \mathfrak{q}^{(n)}$, and since $x \notin \mathfrak{q}$ (by minimality of $\mathfrak{p}$) and x is a unit in $R_\mathfrak{q}$, $r \in \mathfrak{q}^{(n)}$. Hence $\mathfrak{q}^{(n)} = \mathfrak{q}^{(n+1)} + x\mathfrak{q}^{(n)}$, and Nakayama's lemma gives $\mathfrak{q}^{(n)} = \mathfrak{q}^{(n+1)}$. Localising, $\mathfrak{q}^n R_\mathfrak{q} = \mathfrak{q}^{n+1} R_\mathfrak{q}$, and Nakayama in $R_\mathfrak{q}$ gives $\mathfrak{q}^n R_\mathfrak{q} = 0$. So every prime of $R_\mathfrak{q}$, which contains $0 = (\mathfrak{q}R_\mathfrak{q})^n$, equals $\mathfrak{q}R_\mathfrak{q}$, and $\operatorname{ht}\mathfrak{q} = 0$.

For the general statement, argue by induction on r, again with $(R, \mathfrak{p})$ local. Let $\mathfrak{q} \subsetneq \mathfrak{p}$ be a prime such that there is no prime strictly between them; it suffices to show $\operatorname{ht}\mathfrak{q} \leq r-1$. As $\mathfrak{p}$ is minimal over $(x_1, \ldots, x_r)$, some x_i, say x_r, is not in $\mathfrak{q}$. Then $\mathfrak{p}$ is minimal over $\mathfrak{q} + (x_r)$, so $R/(\mathfrak{q} + (x_r))$ is Artinian and $x_i^N \in \mathfrak{q} + (x_r)$ for $i < r$: write $x_i^N = y_i + a_i x_r$ with $y_i \in \mathfrak{q}$. Every prime containing $(y_1, \ldots, y_{r-1}, x_r)$ contains all x_i, so $\mathfrak{p}$ is minimal over $(y_1, \ldots, y_{r-1}, x_r)$, hence $\mathfrak{p}/I$ is minimal over $(\bar{x}_r)$ in R/I, $I = (y_1, \ldots, y_{r-1})$. By the case $r = 1$, $\operatorname{ht}(\mathfrak{p}/I) \leq 1$, so $\mathfrak{q}/I$ is a minimal prime of R/I, that is, $\mathfrak{q}$ is minimal over I, and by induction $\operatorname{ht}\mathfrak{q} \leq r-1$. □

Corollary 14.9.6. *A Noetherian local ring $(R, \mathfrak{m}, k)$ has $\dim R \leq \dim_k \mathfrak{m}/\mathfrak{m}^2 < \infty$.*

Proof. By Corollary 14.4.3, $\mathfrak{m}$ is generated by $\dim_k \mathfrak{m}/\mathfrak{m}^2$ elements, and $\operatorname{ht}\mathfrak{m} = \dim R$. □

14.10 Completions

Lemma 14.10.1 (Artin–Rees)**.** *Let R be Noetherian, I an ideal, M a finitely generated module and $N \subseteq M$ a submodule. There is c such that $I^n M \cap N = I^{n-c}(I^c M \cap N)$ for all $n \geq c$.*

Proof. The *Rees algebra* $R^* = \bigoplus_n I^n$ is a finitely generated R-algebra (generated by generators of I in degree 1), hence Noetherian, and $M^* = \bigoplus_n I^n M$ is a finitely generated graded R^*-module. Its graded submodule $N^* = \bigoplus_n (I^n M \cap N)$ is therefore finitely generated, by homogeneous elements of degrees at most some c. For $n \geq c$, this means $I^n M \cap N = \sum_{j \leq c} I^{n-j}(I^j M \cap N) \subseteq I^{n-c}(I^c M \cap N)$, and the reverse inclusion is clear. □

Theorem 14.10.2 (Krull's intersection theorem)**.** *Let R be Noetherian, I an ideal and M finitely generated, and $N = \bigcap_n I^n M$. Then $IN = N$, so $aN = 0$ for some $a \in 1 + I$. If $I \subseteq J(R)$, for instance if R is local and $I \neq R$, then $\bigcap_n I^n M = 0$.*

Proof. By Lemma 14.10.1, $N = I^{c+1} M \cap N = I(I^c M \cap N) = IN$. Apply Theorem 14.4.2. □

Definition 14.10.3. The I-adic *completion* of a module M is $\hat{M} = \lim_n M/I^n M$, the inverse limit (Example 6.8.3) of the quotients. For $M = R$ it is a ring $\hat{R}$, and there is a natural map $M \to \hat{M}$, injective for R Noetherian local, $I = \mathfrak{m}$ and M finitely generated, by Theorem 14.10.2.

Example 14.10.4. The completion of $k[x_1, \dots, x_n]$ at $(x_1, \dots, x_n)$ is the power series ring $k[[x_1, \dots, x_n]]$, and the completion of $\mathbb{Z}$ at (p) is the ring $\mathbb{Z}_p$ of p-adic integers. For R Noetherian, $\hat{R}$ is Noetherian and flat over R, and completion is exact on finitely generated modules [AM69, Chapter 10].

14.11 Regular local rings and Dedekind domains

Definition 14.11.1. A Noetherian local ring $(R, \mathfrak{m}, k)$ is *regular* if $\dim R = \dim_k \mathfrak{m}/\mathfrak{m}^2$. A *discrete valuation ring* (DVR) is a domain R with a surjective map $v\colon \mathrm{Frac}(R)^\times \to \mathbb{Z}$ such that $v(xy) = v(x) + v(y)$, $v(x+y) \geq \min(v(x), v(y))$, and $R = \{0\} \cup \{x : v(x) \geq 0\}$. A *Dedekind domain* is a Noetherian normal domain of dimension at most 1.

Theorem 14.11.2. *For a Noetherian local domain $(R, \mathfrak{m}, k)$ of dimension 1, the following are equivalent: R is a DVR; R is normal; $\mathfrak{m}$ is principal; R is regular.*

Proof. DVR $\Rightarrow$ normal: if $x \notin R$ satisfies a monic equation $x^n + a_1 x^{n-1} + \cdots + a_n = 0$, then $v(x) < 0$ and $v(x^n)$ is smaller than the valuation of every other term, a contradiction.

Normal $\Rightarrow$ $\mathfrak{m}$ principal: the only primes are 0 and $\mathfrak{m}$, so for $0 \neq a \in \mathfrak{m}$, $R/(a)$ is Artinian and $\mathfrak{m}^n \subseteq (a)$, $\mathfrak{m}^{n-1} \not\subseteq (a)$ for some $n \geq 1$. Choose $b \in \mathfrak{m}^{n-1} \setminus (a)$ and let $x = a/b \in \mathrm{Frac}(R)$. Then $x^{-1} \notin R$ and $x^{-1}\mathfrak{m} \subseteq R$ (since $b\mathfrak{m} \subseteq \mathfrak{m}^n \subseteq (a)$). If $x^{-1}\mathfrak{m} \subseteq \mathfrak{m}$, apply Lemma 14.4.1 to multiplication by x^{-1} on the finitely generated module $\mathfrak{m}$ (with $I = R$): the resulting monic polynomial in x^{-1} kills the nonzero elements of $\mathfrak{m} \subseteq \mathrm{Frac}(R)$, hence vanishes at x^{-1}, so x^{-1} is integral over R, contradicting normality. So $x^{-1}\mathfrak{m}$ is an ideal not contained in $\mathfrak{m}$, that is, $x^{-1}\mathfrak{m} = R$, and $\mathfrak{m} = xR$.

$\mathfrak{m}$ principal $\Rightarrow$ DVR: let $\mathfrak{m} = (t)$. By Krull's intersection theorem (Theorem 14.10.2 below), $\bigcap_n \mathfrak{m}^n = 0$, so every $0 \neq r \in R$ is $r = ut^n$ with u a unit and n unique; put $v(ut^n/u't^{n'}) = n - n'$.

$\mathfrak{m}$ principal $\Leftrightarrow$ regular: $\dim_k \mathfrak{m}/\mathfrak{m}^2 \geq \dim R = 1$ by Corollary 14.9.6, and it equals 1 iff $\mathfrak{m}$ is principal by Corollary 14.4.3. □

Remark 14.11.3. Every regular local ring is a domain, and in fact a UFD [Mat86, Theorems 14.3 and 20.3]. The local rings $k[x_1, \dots, x_n]_{(x_1,\dots,x_n)}$ are regular of dimension n: the images of the x_i form a basis of $\mathfrak{m}/\mathfrak{m}^2$, and the dimension is at least n because of the chain $0 \subsetneq (x_1) \subsetneq \cdots$, and at most n by Corollary 14.9.6. Regularity is the algebraic counterpart of smoothness (Chapter 53).

Theorem 14.11.4. *In a Dedekind domain R every nonzero ideal I is uniquely a product $\mathfrak{p}_1^{n_1} \cdots \mathfrak{p}_r^{n_r}$ of distinct nonzero primes.*

Proof. If $I = R$ take the empty product. Otherwise let $I = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_r$ be a primary decomposition with distinct primes $\mathfrak{p}_i = \sqrt{\mathfrak{q}_i}$, which are nonzero, hence maximal. The $\mathfrak{q}_i$ are pairwise comaximal (their radicals are distinct maximal ideals), so $I = \mathfrak{q}_1 \cdots \mathfrak{q}_r$ by Theorem 8.3.3. Each $R_{\mathfrak{p}_i}$ is a Noetherian local domain of dimension 1, and it is normal: if $x \in \mathrm{Frac}(R)$ satisfies a monic equation with coefficients $a_j/s_j \in R_{\mathfrak{p}_i}$, then with $s = \prod_j s_j$ the element sx satisfies a monic equation over R, so $sx \in R$ and $x \in R_{\mathfrak{p}_i}$. By Theorem 14.11.2 it is a DVR, so $\mathfrak{q}_i R_{\mathfrak{p}_i} = \mathfrak{p}_i^{n_i} R_{\mathfrak{p}_i}$ for some n_i. Both $\mathfrak{q}_i$ and $\mathfrak{p}_i^{n_i}$ are $\mathfrak{p}_i$-primary (an ideal whose radical is a maximal ideal $\mathfrak{m}$ is $\mathfrak{m}$-primary, because in the quotient every element outside $\mathfrak{m}$ is a unit), and a $\mathfrak{p}$-primary ideal $\mathfrak{q}$ is the preimage of $\mathfrak{q}R_{\mathfrak{p}}$ (if $sx \in \mathfrak{q}$ with $s \notin \mathfrak{p}$ then $x \in \mathfrak{q}$); so $\mathfrak{q}_i = \mathfrak{p}_i^{n_i}$. Uniqueness: localising a factorisation at $\mathfrak{p}$ gives $IR_{\mathfrak{p}} = \mathfrak{p}^n R_{\mathfrak{p}}$ with n the exponent of $\mathfrak{p}$, which determines n as $v_{\mathfrak{p}}$ of a generator. □

Example 14.11.5. The ring $\mathbb{Z}[\sqrt{-5}]$ is a Dedekind domain (it is the integral closure of $\mathbb{Z}$ in $\mathbb{Q}(\sqrt{-5})$, see Exercise 14.13.2). Although $6 = 2\cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$ has two factorisations into irreducibles (Counterexample 8.5.6), the ideal (6) factors uniquely into primes: $(2) = \mathfrak{p}^2$ with $\mathfrak{p} = (2, 1+\sqrt{-5})$, and $(3) = \mathfrak{r}\bar{\mathfrak{r}}$ with $\mathfrak{r} = (3, 1+\sqrt{-5})$, $\bar{\mathfrak{r}} = (3, 1-\sqrt{-5})$, while $(1\pm\sqrt{-5}) = \mathfrak{p}\mathfrak{r}$, $\mathfrak{p}\bar{\mathfrak{r}}$.

14.12 Kähler differentials

Definition 14.12.1. Let $A \to B$ be a ring homomorphism and M a B-module. An *A-derivation* $D\colon B \to M$ is an A-linear map with $D(bb') = bD(b') + b'D(b)$. The *module of Kähler differentials* $\Omega_{B/A}$ is the free B-module on symbols db, $b \in B$, modulo the relations $d(b+b') - db - db'$, $d(bb') - b\,db' - b'\,db$ and da for a in the image of A; the map $d\colon B \to \Omega_{B/A}$ is an A-derivation.

Proposition 14.12.2. *1.* $\mathrm{Hom}_B(\Omega_{B/A}, M) \cong \mathrm{Der}_A(B, M)$, $\varphi \mapsto \varphi \circ d$, *naturally in* M.

2. $\Omega_{A[x_1,\dots,x_n]/A}$ *is free with basis* $dx_1, \dots, dx_n$, *and* $df = \sum_i (\partial f/\partial x_i) dx_i$.

3. *For* $A \to B \to C$ *there is an exact sequence* $C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to \Omega_{C/B} \to 0$.

4. *If* $C = B/I$, *there is an exact sequence* $I/I^2 \xrightarrow{\delta} C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to 0$ *with* $\delta(\bar{f}) = 1 \otimes df$.

5. $S^{-1}\Omega_{B/A} \cong \Omega_{S^{-1}B/A}$ *for a multiplicative* $S \subseteq B$.

Proof. (1) is the universal property of the construction. (2) The formal partial derivatives define a derivation $A[x] \to \bigoplus A[x]\, e_i$, $f \mapsto \sum_i (\partial f/\partial x_i) e_i$; a derivation is determined by its values on the x_i, which can be arbitrary. By (1), Ω is free on the dx_i. (3) and (4): a sequence $X \to Y \to Z \to 0$ of C-modules is exact if and only if $0 \to \mathrm{Hom}_C(Z, M) \to \mathrm{Hom}_C(Y, M) \to \mathrm{Hom}_C(X, M)$ is exact for every C-module M (for the nontrivial direction take $M = Z/\mathrm{im}(Y)$ and $M = \mathrm{coker}(X \to Y)$). By (1), $\mathrm{Hom}_C(C \otimes_B \Omega_{B/A}, M) = \mathrm{Der}_A(B, M)$ and $\mathrm{Hom}_C(I/I^2, M) = \mathrm{Hom}_B(I, M)$, so it suffices to show that for every C-module M the sequences $0 \to \mathrm{Der}_B(C, M) \to \mathrm{Der}_A(C, M) \to \mathrm{Der}_A(B, M)$ and $0 \to \mathrm{Der}_A(C, M) \to \mathrm{Der}_A(B, M) \to \mathrm{Hom}_B(I, M)$ are exact, which is immediate: a derivation of C over A vanishing on B is a B-derivation; and an A-derivation of B into a C-module that vanishes on I factors through $C = B/I$ (it automatically vanishes on I^2). (5) Derivations $S^{-1}B \to M$ correspond to derivations $B \to M$ into $S^{-1}B$-modules by the quotient rule $D(b/s) = (sDb - bDs)/s^2$. □

Example 14.12.3. For $B = k[x,y]/(y^2 - x^3)$, Proposition 14.12.2(4) gives $\Omega_{B/k} = (B\,dx \oplus B\,dy)/(2y\,dy - 3x^2 dx)$. At the origin, $\Omega_{B/k} \otimes k$ has dimension 2 although B has dimension 1; this detects the singularity of the cusp. For a finite separable field extension L/K one has $\Omega_{L/K} = 0$: if $L = K(\gamma)$ with minimal polynomial f, then $0 = d(f(\gamma)) = f'(\gamma)\,d\gamma$ and $f'(\gamma) \neq 0$ (Theorem 9.6.3 and Proposition 9.4.2).

14.13 Exercises

Exercise 14.13.1. Describe $\mathrm{Spec}\,\mathbb{Z}$, $\mathrm{Spec}\,\mathbb{Z}[x]$ (in terms of prime numbers and irreducible polynomials) and $\mathrm{Spec}\,k[x,y]$ for k algebraically closed.

Exercise 14.13.2. Let $d \neq 0, 1$ be a squarefree integer with $d \equiv 2, 3 \pmod 4$. Show that the integral closure of $\mathbb{Z}$ in $\mathbb{Q}(\sqrt{d})$ is $\mathbb{Z}[\sqrt{d}]$, and deduce that $\mathbb{Z}[\sqrt{-5}]$ is a Dedekind domain.

Exercise 14.13.3. Let $(R, \mathfrak{m})$ be a local ring and M a finitely generated R-module that is a direct summand of a free module. Show that M is free.

Exercise 14.13.4. Let $K = \mathbb{F}_p(t)$ and $L = K(t^{1/p})$. Show that $\Omega_{L/K}$ is one-dimensional over L.

Exercise 14.13.5. (Hensel's lemma.) Let $f \in \mathbb{Z}_p[x]$ and $a \in \mathbb{Z}_p$ with $f(a) \equiv 0 \pmod{p}$ and $f'(a) \not\equiv 0 \pmod{p}$. Show that there is a unique $b \in \mathbb{Z}_p$ with $f(b) = 0$ and $b \equiv a \pmod{p}$.

Exercise 14.13.6. Let k be a field and $f \in k[x_1, \ldots, x_n]$ irreducible. Show that $\dim k[x_1, \ldots, x_n]/(f) = n - 1$.

Chapter 15

Homological Algebra

15.1 Introduction

Homological algebra measures the failure of exactness. Its basic objects are complexes and their cohomology; its basic tools are the long exact sequence and derived functors. Everything in this project that is called a cohomology theory (singular cohomology in Chapter 22, sheaf cohomology in Chapter 26, de Rham and Dolbeault cohomology in Chapters 37 and 46) is built with the machinery of this chapter.

We work in abelian categories, but prove the diagram lemmas for modules; by the Freyd–Mitchell embedding theorem they then hold in every abelian category (Remark 15.2.5). References are [Wei94], [CE56] and [GM03].

Prerequisites. Chapter 6 (Categories) and Chapter 8 (Rings and Modules).

On the way to the Hodge conjecture. Needed: complexes and the long exact sequence, projective and injective objects, derived functors (the basis of sheaf cohomology), double complexes (for the de Rham and Dolbeault theorems) and the Künneth formula. Ext and Tor (Section 15.8) can be read when needed.

15.2 Abelian categories

Definition 15.2.1. An additive category $\mathcal{A}$ (Definition 6.12.1) is *abelian* if every morphism has a kernel and a cokernel (Definition 6.12.3), every monomorphism is a kernel of its cokernel, and every epimorphism is a cokernel of its kernel. For $f\colon X \to Y$ the *image* is $\operatorname{im} f = \ker(\operatorname{coker} f)$. A sequence $X \xrightarrow{f} Y \xrightarrow{g} Z$ with $gf = 0$ is *exact* at Y if the induced morphism $\operatorname{im} f \to \ker g$ is an isomorphism. An additive functor between abelian categories is *left exact* if it sends exact sequences $0 \to X \to Y \to Z$ to exact sequences, *right exact* if it sends exact $X \to Y \to Z \to 0$ to exact sequences, and *exact* if both.

Example 15.2.2. For a ring R, the category R-Mod is abelian (Proposition 8.7.3): kernels and cokernels are the usual ones, an injective map is the kernel of the projection onto its cokernel, and a surjective map is the cokernel of the inclusion of its kernel. In particular Ab is abelian. The category of sheaves of abelian groups on a topological space is abelian (Chapter 25). By Theorem 8.9.4, $- \otimes_R N$ is right exact, and $\operatorname{Hom}_R(N, -)$ is left exact.

Lemma 15.2.3. *In an abelian category a morphism that is both a monomorphism and an epimorphism is an isomorphism.*

Proof. Let $f\colon X \to Y$ be both. Its cokernel is $Y \to 0$, since f is an epimorphism; as f is a monomorphism, it is a kernel of $Y \to 0$. But id_Y is also a kernel of $Y \to 0$, so f is an isomorphism by uniqueness of kernels (Lemma 6.8.2). □

Counterexample 15.2.4. The category $\mathcal{F}$ of finitely generated free abelian groups is additive and has kernels (Proposition 7.11.4), but it is not abelian. The morphism $2\colon \mathbb{Z} \to \mathbb{Z}$ is a monomorphism, and it is an epimorphism in $\mathcal{F}$: if $g \circ 2 = 0$ for $g\colon \mathbb{Z} \to \mathbb{Z}^n$, then $2g(1) = 0$, so $g = 0$. It is not an isomorphism, contradicting Lemma 15.2.3.

Remark 15.2.5. By the Freyd–Mitchell embedding theorem, every small abelian category admits a fully faithful exact functor into R-Mod for some ring R [Wei94, Theorem 1.6.1]. Every statement about a finite diagram in an abelian category $\mathcal{A}$ that asserts exactness, or the existence of morphisms constructed from kernels, cokernels and compositions, involves only a small abelian subcategory of $\mathcal{A}$; hence it suffices to prove it for modules, where one may argue with elements ("diagram chasing"). We use this principle for Lemmas 15.4.1 and 15.4.2, and wherever we prove a statement about abelian categories by a chase.

15.3 Complexes

Definition 15.3.1. A *complex* (or cochain complex) $A^\bullet$ in an abelian category $\mathcal{A}$ is a family of objects A^n, $n \in \mathbb{Z}$, with morphisms $d^n\colon A^n \to A^{n+1}$ such that $d^{n+1}d^n = 0$. Its *cocycles*, *coboundaries* and *cohomology* are $Z^n = \ker d^n$, $B^n = \operatorname{im} d^{n-1}$ and $H^n(A^\bullet) = Z^n/B^n$. A *morphism of complexes* $f\colon A^\bullet \to B^\bullet$ is a family $f^n\colon A^n \to B^n$ with $df = fd$; it induces $H^n(f)$. It is a *quasi-isomorphism* if all $H^n(f)$ are isomorphisms. A complex is *acyclic* (or exact) if all H^n vanish, and *bounded below* if $A^n = 0$ for $n \ll 0$. The complexes form an abelian category $\mathrm{Ch}(\mathcal{A})$, with kernels and cokernels computed degreewise.

Notation 15.3.2. A *chain complex* $C_\bullet$ has differentials $d_n\colon C_n \to C_{n-1}$ and *homology* $H_n = \ker d_n/\operatorname{im} d_{n+1}$. Setting $C^n = C_{-n}$ turns it into a complex, with $H^n = H_{-n}$; all statements about complexes apply to chain complexes in this way. For a complex $A^\bullet$ and $k \in \mathbb{Z}$, the *shift* $A[k]$ has $A[k]^n = A^{n+k}$ and differential $(-1)^k d$.

Definition 15.3.3. Two morphisms $f, g\colon A^\bullet \to B^\bullet$ are *homotopic*, $f \simeq g$, if there are morphisms $h^n\colon A^n \to B^{n-1}$ with $f^n - g^n = d^{n-1}h^n + h^{n+1}d^n$. A morphism f is a *homotopy equivalence* if there is g with $gf \simeq \mathrm{id}$ and $fg \simeq \mathrm{id}$.

Lemma 15.3.4. *Homotopic morphisms induce the same maps on cohomology; homotopy equivalences are quasi-isomorphisms. Additive functors preserve homotopies.*

Proof. For a cocycle z, $f(z) - g(z) = dh(z) + hd(z) = dh(z)$ is a coboundary. The second statement follows, and the third because the defining identity is preserved by additive functors. □

Definition 15.3.5. The *mapping cone* of $f\colon A^\bullet \to B^\bullet$ is the complex $\mathrm{Cone}(f)$ with $\mathrm{Cone}(f)^n = A^{n+1} \oplus B^n$ and $d(a, b) = (-da, f(a) + db)$.

15.4 The long exact sequence

Lemma 15.4.1 (Snake lemma)**.** *Consider a commutative diagram of modules with exact rows*

$$\begin{array}{ccccccccc} & & A' & \xrightarrow{i'} & B' & \xrightarrow{p'} & C' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle h} & & \\ 0 & \longrightarrow & A & \xrightarrow{i} & B & \xrightarrow{p} & C & & \end{array}$$

There is a homomorphism $\delta\colon \ker h \to \operatorname{coker} f$ *such that the sequence*

$$\ker f \to \ker g \to \ker h \xrightarrow{\delta} \operatorname{coker} f \to \operatorname{coker} g \to \operatorname{coker} h$$

is exact. If i' *is injective so is* $\ker f \to \ker g$*, and if* p *is surjective so is* $\operatorname{coker} g \to \operatorname{coker} h$*.*

Proof. Definition of δ*.* Let $c' \in \ker h$. Choose $b' \in B'$ with $p'(b') = c'$. Then $p(g(b')) = h(c') = 0$, so $g(b') = i(a)$ for a unique $a \in A$; put $\delta(c') = [a]$. If b' is replaced by $b' + i'(a')$, then a is replaced by $a + f(a')$, with the same class; so δ is well defined, and it is clearly a homomorphism.

Exactness at $\ker g$. The composite is zero. If $b' \in \ker g$ and $p'(b') = 0$, then $b' = i'(a')$ and $i(f(a')) = g(b') = 0$, so $f(a') = 0$.

Exactness at $\ker h$. If $c' = p'(b')$ with $g(b') = 0$, then $a = 0$ and $\delta(c') = 0$. Conversely if $\delta(c') = 0$, then $a = f(a'')$, and $b' - i'(a'')$ is a preimage of c' with $g(b' - i'(a'')) = i(a) - i(f(a'')) = 0$.

Exactness at $\operatorname{coker} f$. The image of $\delta(c')$ in $\operatorname{coker} g$ is the class of $i(a) = g(b')$, which is zero. Conversely, if $i(a) = g(b')$ for some b', then $c' = p'(b')$ satisfies $h(c') = p(g(b')) = pi(a) = 0$ and $\delta(c') = [a]$.

Exactness at $\operatorname{coker} g$. The composite is zero. If $b \in B$ maps to zero in $\operatorname{coker} h$, then $p(b) = h(p'(b'))$ for some b', so $p(b - g(b')) = 0$ and $b - g(b') = i(a)$; hence $[b]$ is the image of $[a]$.

The last two statements are clear. □

Lemma 15.4.2 (Five lemma)**.** *Consider a commutative diagram of modules with exact rows* $A_1 \to A_2 \to A_3 \to A_4 \to A_5$ *and* $B_1 \to B_2 \to B_3 \to B_4 \to B_5$ *and vertical maps* $f_1, \dots, f_5$*. If* f_2 *and* f_4 *are isomorphisms,* f_1 *is surjective and* f_5 *is injective, then* f_3 *is an isomorphism.*

Proof. Write $\alpha_i\colon A_i \to A_{i+1}$ and $\beta_i\colon B_i \to B_{i+1}$. *Injectivity:* let $f_3(x) = 0$. Then $f_4\alpha_3(x) = 0$, so $\alpha_3(x) = 0$ and $x = \alpha_2(y)$. Now $\beta_2 f_2(y) = 0$, so $f_2(y) = \beta_1(z)$ and $z = f_1(w)$. Then $f_2(y - \alpha_1(w)) = 0$, so $y = \alpha_1(w)$ and $x = \alpha_2\alpha_1(w) = 0$. *Surjectivity:* let $u \in B_3$. Choose $x \in A_4$ with $f_4(x) = \beta_3(u)$. Then $f_5\alpha_4(x) = \beta_4\beta_3(u) = 0$, so $\alpha_4(x) = 0$ and $x = \alpha_3(y)$. Then $\beta_3(u - f_3(y)) = 0$, so $u - f_3(y) = \beta_2(v)$ with $v = f_2(t)$, and $u = f_3(y + \alpha_2(t))$. □

Theorem 15.4.3 (Long exact sequence, or zig-zag lemma)**.** *A short exact sequence* $0 \to A^\bullet \xrightarrow{f} B^\bullet \xrightarrow{g} C^\bullet \to 0$ *of complexes in an abelian category induces a long exact sequence*

$$\cdots \to H^n(A) \to H^n(B) \to H^n(C) \xrightarrow{\delta} H^{n+1}(A) \to H^{n+1}(B) \to \cdots,$$

natural in the short exact sequence. For $c \in Z^n(C)$ *(in the case of modules),* $\delta[c]$ *is the class of* a *where* $f(a) = d(b)$ *and* $g(b) = c$*.*

Proof. Applying the snake lemma to the vertical maps d^{n-1} between the short exact sequences in degrees $n-1$ and n, the cokernel sequence $A^n/B^n(A) \to B^n/B^n(B) \to C^n/B^n(C) \to 0$ is exact; applying it to d^{n+1}, the kernel sequence $0 \to Z^{n+1}(A) \to Z^{n+1}(B) \to Z^{n+1}(C)$ is exact. The differential d^n induces vertical maps from the first of these rows to the second, whose kernels are the H^n and whose cokernels are the H^{n+1}. Apply Lemma 15.4.1. Naturality follows from the explicit formula for δ. □

Remark 15.4.4. The name *zig-zag lemma* comes from the path that defines the connecting map δ. Start from a cocycle $c \in C^n$; go up to a preimage $b \in B^n$ with $g(b) = c$; go across by the differential to $d(b) \in B^{n+1}$, which satisfies $g(d(b)) = d(g(b)) = d(c) = 0$; and go down to the unique $a \in A^{n+1}$ with $f(a) = d(b)$. Then $\delta[c] = [a]$:

$$\begin{array}{ccccc} & & b & \xmapsto{g} & c \\ & & \downarrow{\scriptstyle d} & & \downarrow{\scriptstyle d} \\ a & \xmapsto{f} & d(b) & \xmapsto{g} & 0 \end{array}$$

The element a depends on the choice of b, but its class does not; Exercise 15.10.2 checks this and the exactness of the long sequence directly, by chasing elements through the diagram, without the snake lemma. In singular homology, where the short exact sequence is $0 \to C_\bullet(A) \to C_\bullet(X) \to C_\bullet(X, A) \to 0$, the recipe says: a relative cycle is a chain in X whose boundary lies in A, and δ sends it to that boundary.

Proposition 15.4.5. *For $f\colon A^\bullet \to B^\bullet$ there is a short exact sequence $0 \to B^\bullet \to \mathrm{Cone}(f) \to A[1]^\bullet \to 0$ whose connecting map $H^n(A[1]) = H^{n+1}(A) \to H^{n+1}(B)$ is $H^{n+1}(f)$. In particular f is a quasi-isomorphism if and only if $\mathrm{Cone}(f)$ is acyclic.*

Proof. The maps $b \mapsto (0, b)$ and $(a, b) \mapsto a$ are morphisms of complexes (with the sign convention of Notation 15.3.2 for $A[1]$). For a cocycle $a \in A^{n+1}$, the element $(a, 0)$ lifts it, and $d(a, 0) = (-da, f(a)) = (0, f(a))$; so $\delta[a] = [f(a)]$. The last statement follows from the long exact sequence. □

15.5 Projective and injective objects

Definition 15.5.1. An object P of an abelian category is *projective* if $\mathrm{Hom}(P, -)$ is exact, that is, every morphism $P \to Y$ lifts along every epimorphism $X \to Y$. An object I is *injective* if $\mathrm{Hom}(-, I)$ is exact, that is, every morphism $X \to I$ extends along every monomorphism $X \to Y$. The category has *enough projectives* (*injectives*) if every object is a quotient of a projective (a subobject of an injective).

Proposition 15.5.2. *An R-module is projective if and only if it is a direct summand of a free module. R-Mod has enough projectives.*

Proof. Free modules are projective by Proposition 8.7.5 (choose lifts of the images of a basis), and direct summands of projectives are projective. If P is projective, choose a surjection $F \to P$ from a free module; the identity of P lifts to a section, so P is a direct summand of F by Proposition 8.7.7. Every module is a quotient of a free module. □

Proposition 15.5.3 (Baer's criterion)**.** *An R-module I is injective if and only if every homomorphism $J \to I$ from a left ideal $J \subseteq R$ extends to R.*

Proof. Necessity is clear. Let $N \subseteq M$ and $\varphi\colon N \to I$. By Zorn's lemma choose a maximal extension $\psi\colon N' \to I$ with $N \subseteq N' \subseteq M$. If $m \in M \setminus N'$, let $J = \{r : rm \in N'\}$ and extend $r \mapsto \psi(rm)$ to $\theta\colon R \to I$. Then $n' + rm \mapsto \psi(n') + \theta(r)$ is a well-defined extension of ψ to $N' + Rm$ (if $n' + rm = 0$ then $r \in J$ and $\theta(r) = \psi(rm) = -\psi(n')$), contradicting maximality. □

Theorem 15.5.4. *R-Mod has enough injectives. An abelian group D is injective if and only if it is* divisible*: for every $x \in D$ and $n \geq 1$ there is y with $ny = x$.*

Proof. By Baer's criterion and Proposition 7.2.10, D is injective iff every homomorphism $n\mathbb{Z} \to D$ extends to $\mathbb{Z}$, iff divisible. Every abelian group M embeds in a divisible group: write $M = F/K$ with $F = \mathbb{Z}^{(S)}$ free; then $M \subseteq \mathbb{Q}^{(S)}/K$, which is divisible.

Let M be an R-module and $M \subseteq D$ an embedding of abelian groups with D divisible. Make $\mathrm{Hom}_{\mathbb{Z}}(R, D)$ an R-module by $(r\varphi)(s) = \varphi(sr)$. For every R-module N there is a natural bijection $\mathrm{Hom}_R(N, \mathrm{Hom}_{\mathbb{Z}}(R, D)) \cong \mathrm{Hom}_{\mathbb{Z}}(N, D)$, $\psi \mapsto (n \mapsto \psi(n)(1))$, with inverse

$\chi \mapsto (n \mapsto (s \mapsto \chi(sn)))$. The right side is exact in N since D is injective, so $\mathrm{Hom}_{\mathbb{Z}}(R, D)$ is an injective R-module. The map $M \to \mathrm{Hom}_{\mathbb{Z}}(R, D)$, $m \mapsto (s \mapsto sm)$, is R-linear and injective. □

15.6 Derived functors

In this section $\mathcal{A}$ and $\mathcal{B}$ are abelian categories.

Definition 15.6.1. An *injective resolution* of an object X is an exact sequence $0 \to X \to I^0 \to I^1 \to \cdots$ with all I^n injective; we regard $I^\bullet$ as a complex with a quasi-isomorphism $X \to I^\bullet$ (X in degree 0). Projective resolutions $\cdots \to P_1 \to P_0 \to X \to 0$ are defined dually. If $\mathcal{A}$ has enough injectives, every object has an injective resolution: embed X in I^0, embed I^0/X in I^1, and so on.

Theorem 15.6.2 (Comparison theorem)**.** *Let $0 \to X \to E^\bullet$ be exact with $E^n = 0$ for $n < 0$, and let $0 \to Y \to I^\bullet$ be a complex with all I^n injective, $I^n = 0$ for $n < 0$. Every morphism $\varphi\colon X \to Y$ extends to a morphism of complexes $E^\bullet \to I^\bullet$, and any two extensions are homotopic.*

Proof. Write $\varepsilon\colon X \to E^0$ and $\eta\colon Y \to I^0$. The morphism $\eta\varphi$ extends along the monomorphism ε to $f^0\colon E^0 \to I^0$. Suppose $f^0, \dots, f^n$ are constructed commuting with the differentials (and with ε, η). Then df^n vanishes on the image of $E^{n-1} \to E^n$ (or of X when $n = 0$), so it factors through $E^n/\mathrm{im}(E^{n-1}) \hookrightarrow E^{n+1}$, and extends along this monomorphism to $f^{n+1}\colon E^{n+1} \to I^{n+1}$ by injectivity.

If f, g both extend φ, let $u = f - g$, which extends 0, so $u^0\varepsilon = 0$. Put $h^0 = 0\colon E^0 \to I^{-1} = 0$. Suppose $h^0, \dots, h^n$ are constructed with $u^k = dh^k + h^{k+1}d$ for all $k < n$. For $n \geq 1$,

$$(u^n - dh^n)d = u^n d - dh^n d = du^{n-1} - d(u^{n-1} - dh^{n-1}) = ddh^{n-1} = 0,$$

using that u commutes with the differentials and the identity for $k = n - 1$; for $n = 0$, $(u^0 - dh^0)\varepsilon = u^0\varepsilon = 0$. So $u^n - dh^n$ vanishes on the image of $E^{n-1} \to E^n$ (of $X \to E^0$ if $n = 0$), factors through the monomorphism $E^n/\mathrm{im} \hookrightarrow E^{n+1}$, and extends to $h^{n+1}\colon E^{n+1} \to I^n$ with $h^{n+1}d = u^n - dh^n$. □

Lemma 15.6.3 (Horseshoe lemma)**.** *Let $0 \to X' \to X \to X'' \to 0$ be exact, and let $X' \to I'^\bullet$, $X'' \to I''^\bullet$ be injective resolutions. There is an injective resolution $X \to I^\bullet$ with $I^n = I'^n \oplus I''^n$ such that $0 \to I'^\bullet \to I^\bullet \to I''^\bullet \to 0$ (with the inclusion and projection in each degree) is a short exact sequence of complexes compatible with the given sequence.*

Proof. Let $\varepsilon'\colon X' \to I'^0$, $\varepsilon''\colon X'' \to I''^0$, and $\iota\colon X' \to X$, $\pi\colon X \to X''$. Extend ε' along ι to $\lambda\colon X \to I'^0$ and define $\varepsilon = (\lambda, \varepsilon''\pi)\colon X \to I'^0 \oplus I''^0$. The diagram $0 \to X' \to X \to X'' \to 0$ over $0 \to I'^0 \to I^0 \to I''^0 \to 0$ commutes, and the snake lemma shows that ε is a monomorphism and that $0 \to \mathrm{coker}\,\varepsilon' \to \mathrm{coker}\,\varepsilon \to \mathrm{coker}\,\varepsilon'' \to 0$ is exact. Apply the same construction to this sequence and the resolutions $I'^{\geq 1}$, $I''^{\geq 1}$ of the cokernels, and continue by induction. □

Definition 15.6.4. Let $\mathcal{A}$ have enough injectives and $F\colon \mathcal{A} \to \mathcal{B}$ be a left exact functor. For each X choose an injective resolution $X \to I_X^\bullet$ and define the *right derived functors* $R^nF(X) = H^n(F(I_X^\bullet))$. A morphism $X \to Y$ induces a morphism of resolutions, unique up to homotopy (Theorem 15.6.2), hence a well-defined morphism $R^nF(X) \to R^nF(Y)$ by Lemma 15.3.4. Left derived functors L_nF of a right exact functor on a category with enough projectives are defined dually using projective resolutions.

Theorem 15.6.5. *1. The R^nF are additive functors, independent of the choice of resolutions up to canonical isomorphism, with $R^nF = 0$ for $n < 0$ and $R^0F \cong F$.*

2. *$R^nF(I) = 0$ for $n > 0$ and I injective.*

3. *Every short exact sequence $0 \to X' \to X \to X'' \to 0$ induces a long exact sequence $0 \to F(X') \to F(X) \to F(X'') \to R^1F(X') \to R^1F(X) \to \cdots$, natural in the short exact sequence.*

Proof. (1) Two resolutions of X are related by morphisms extending id_X in both directions, whose composites are homotopic to the identities by the uniqueness part of Theorem 15.6.2; applying F gives homotopy equivalences and canonical isomorphisms on cohomology. Functoriality and additivity follow from uniqueness up to homotopy. $R^0F(X) = \ker(F(I^0) \to F(I^1)) = F(\ker(I^0 \to I^1)) = F(X)$ by left exactness. (2) Use the resolution $0 \to I \to I \to 0$. (3) Choose resolutions of X' and X'' and form the resolution of X given by Lemma 15.6.3. The sequence $0 \to I'^\bullet \to I^\bullet \to I''^\bullet \to 0$ is split in every degree, so it stays exact after applying the additive functor F. Apply Theorem 15.4.3. Naturality follows from the comparison theorem. □

Proposition 15.6.6. *Call J F-*acyclic *if $R^nF(J) = 0$ for all $n > 0$. If $0 \to X \to J^0 \to J^1 \to \cdots$ is exact with all J^n F-acyclic, then $R^nF(X) \cong H^n(F(J^\bullet))$ for all n.*

Proof. Let $K = \operatorname{coker}(X \to J^0) = \ker(J^1 \to J^2)$, so that $0 \to X \to J^0 \to K \to 0$ is exact and $K \to J^{\geq 1}$ is an F-acyclic resolution. The long exact sequence and acyclicity of J^0 give $R^nF(X) \cong R^{n-1}F(K)$ for $n \geq 2$, and $R^1F(X) \cong \operatorname{coker}(F(J^0) \to F(K))$. By left exactness $F(K) = \ker(F(J^1) \to F(J^2))$, so $R^1F(X) \cong H^1(F(J^\bullet))$. For $n \geq 2$ argue by induction on n, for all objects and resolutions simultaneously: $K \to J^1 \to J^2 \to \cdots$ is an F-acyclic resolution of K, with J^1 in degree 0, so $R^nF(X) \cong R^{n-1}F(K) \cong H^{n-1}(F(J^1) \to F(J^2) \to \cdots) = H^n(F(J^\bullet))$. The case $n = 0$ is left exactness. □

15.7 Double complexes

Definition 15.7.1. A *double complex* $C^{\bullet,\bullet}$ consists of objects $C^{p,q}$ with morphisms $d_h \colon C^{p,q} \to C^{p+1,q}$ and $d_v \colon C^{p,q} \to C^{p,q+1}$ such that $d_h^2 = 0$, $d_v^2 = 0$ and $d_h d_v = d_v d_h$. It is *first quadrant* if $C^{p,q} = 0$ unless $p, q \geq 0$. Its *total complex* is $\mathrm{Tot}^n = \bigoplus_{p+q=n} C^{p,q}$ with $d = d_h + (-1)^p d_v$ on $C^{p,q}$; then $d^2 = 0$.

Lemma 15.7.2. *Let C be a first-quadrant double complex of modules whose rows are exact in positive degrees: for each q, the complex $C^{0,q} \to C^{1,q} \to \cdots$ is exact at $C^{p,q}$ for all $p \geq 1$. Let $K^q = \ker(d_h \colon C^{0,q} \to C^{1,q})$, a complex with differential d_v. Then the inclusion $K^\bullet \to \mathrm{Tot}^\bullet(C)$ is a quasi-isomorphism.*

Proof. The inclusion is a morphism of complexes, since $d = d_v$ on K. *Surjectivity on cohomology.* Let $x = (x^{0,n}, x^{1,n-1}, \ldots, x^{n,0})$ be a cocycle of degree n. Let p be largest with $x^{p,n-p} \neq 0$. If $p \geq 1$, the component of dx in $C^{p+1,n-p}$ is $d_h x^{p,n-p} = 0$ (the other contribution comes from $x^{p+1,n-p-1} = 0$), so $x^{p,n-p} = d_h y$ with $y \in C^{p-1,n-p}$, and $x - dy$ is a cohomologous cocycle whose components vanish in positions $\geq p$. Repeating, we reach a cocycle concentrated in $C^{0,n}$; the vanishing of its $C^{1,n}$-component of d means it lies in K^n, and it is a d_v-cocycle.

Injectivity on cohomology. Let $k \in K^n$ with $k = dy$ for $y \in \mathrm{Tot}^{n-1}$. As above, if $p \geq 1$ is largest with $y^{p,n-1-p} \neq 0$, the component of dy in $C^{p+1,n-1-p}$ is $d_h y^{p,n-1-p}$, which is zero because $dy = k$ lives in $C^{0,n}$ (here $p + 1 \geq 2 > 0$); so $y^{p,n-1-p} = d_h z$ and we replace y by $y - dz$, which does not change dy. We reach $y \in C^{0,n-1}$ with $d_h y$ equal to the $C^{1,n-1}$-component of k, which is 0; so $y \in K^{n-1}$ and $k = d_v y$. □

15.8 Ext and Tor

In this section R is a ring and modules are left R-modules; for Tor we assume R commutative.

Definition 15.8.1. $\operatorname{Ext}^n_R(M,N) = R^n \operatorname{Hom}_R(M,-)(N)$, computed with an injective resolution of N, and $\operatorname{Tor}^R_n(M,N) = L_n(M\otimes_R -)(N)$, computed with a projective resolution of N.

Theorem 15.8.2 (Balance). *If $P_\bullet \to M$ is a projective resolution, then $\operatorname{Ext}^n_R(M,N) \cong H^n(\operatorname{Hom}_R(P_\bullet, N))$. Similarly $\operatorname{Tor}^R_n(M,N) \cong H_n(P_\bullet \otimes_R N)$, and $\operatorname{Tor}^R_n(M,N) \cong \operatorname{Tor}^R_n(N,M)$. Consequently $\operatorname{Ext}^n(-,N)$ are the right derived functors of the contravariant left exact functor $\operatorname{Hom}_R(-,N)$, and there are long exact sequences in both variables.*

Proof. Let $N \to I^\bullet$ be an injective resolution and $C^{p,q} = \operatorname{Hom}_R(P_p, I^q)$, a first-quadrant double complex. For fixed q the row $\operatorname{Hom}_R(P_\bullet, I^q)$ is exact in positive degrees with kernel $\operatorname{Hom}_R(M, I^q)$ in degree 0, because $\operatorname{Hom}_R(-, I^q)$ is exact and $P_\bullet \to M \to 0$ is exact. For fixed p the column $\operatorname{Hom}_R(P_p, I^\bullet)$ is exact in positive degrees with kernel $\operatorname{Hom}_R(P_p, N)$, because P_p is projective. By Lemma 15.7.2, applied to C and to its transpose, both $\operatorname{Hom}_R(M, I^\bullet)$ and $\operatorname{Hom}_R(P_\bullet, N)$ are quasi-isomorphic to $\operatorname{Tot}(C)$. The same argument with $P_p \otimes Q_q$ for projective resolutions P of M and Q of N (projective modules are flat, being summands of free modules) gives the statements for Tor, and symmetry follows from $P_p \otimes Q_q \cong Q_q \otimes P_p$. The long exact sequence in the first variable follows from the horseshoe lemma for projective resolutions and Theorem 15.4.3. □

Example 15.8.3. Using the projective resolution $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z} \to 0$, for every abelian group A: $\operatorname{Hom}(\mathbb{Z}/n\mathbb{Z}, A) = A[n] = \{a : na = 0\}$, $\operatorname{Ext}^1_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, A) = A/nA$, $\mathbb{Z}/n\mathbb{Z} \otimes A = A/nA$ and $\operatorname{Tor}^{\mathbb{Z}}_1(\mathbb{Z}/n\mathbb{Z}, A) = A[n]$; all higher groups vanish. For instance $\operatorname{Ext}^1_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$, although $\operatorname{Hom}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}) = 0$.

Proposition 15.8.4. *A module N is flat if and only if $\operatorname{Tor}^R_1(M,N) = 0$ for all M; then $\operatorname{Tor}^R_n(M,N) = 0$ for all $n \geq 1$. If R is Noetherian local with residue field k and N is finitely generated, then N is flat if and only if it is free, if and only if $\operatorname{Tor}^R_1(k,N) = 0$.*

Proof. If $0 \to M' \to M \to M'' \to 0$ is exact, the long exact sequence $\operatorname{Tor}_1(M'', N) \to M' \otimes N \to M \otimes N$ shows that vanishing of Tor_1 gives injectivity; conversely if N is flat, computing Tor with a projective resolution of M tensored with N (Theorem 15.8.2) gives an exact complex. For the second statement, free implies flat. Suppose $\operatorname{Tor}_1(k,N) = 0$. Choose a minimal set of generators, giving $0 \to K \to R^n \to N \to 0$ with $n = \dim_k N/\mathfrak{m}N$ (Corollary 14.4.3). Tensoring with k gives the exact sequence $0 \to K \otimes k \to k^n \to N \otimes k \to 0$, in which the last map is an isomorphism of n-dimensional spaces; so $K/\mathfrak{m}K = 0$, and $K = 0$ by Nakayama's lemma, as K is finitely generated (R is Noetherian). □

Proposition 15.8.5. *If R is a principal ideal domain, every submodule of a free R-module is free. Hence every R-module has a projective resolution of length at most 1, and $\operatorname{Ext}^n_R = \operatorname{Tor}^R_n = 0$ for $n \geq 2$.*

Proof. Let F be free with basis $(e_i)_{i\in I}$, where I is well-ordered (Theorem 3.7.2), and $M \subseteq F$. For $i \in I$ let $F_{\leq i}$ and $F_{<i}$ be spanned by the e_j with $j \leq i$, respectively $j < i$, let $M_i = M \cap F_{\leq i}$, and let $\pi_i \colon M_i \to R$ be the e_i-coordinate. Its image is an ideal (a_i); if $a_i \neq 0$ choose $m_i \in M_i$ with $\pi_i(m_i) = a_i$. The m_i are linearly independent: in a relation $\sum c_i m_i = 0$, the largest i with $c_i \neq 0$ gives $c_i a_i = 0$ on the e_i-coordinate. They generate M: otherwise let i be least such that M_i contains an element m not in their span. Then $\pi_i(m) = ra_i$, and $m - rm_i$ (or m itself if $a_i = 0$) lies in $M \cap F_{<i}$; having finite support, it lies in some M_j with $j < i$, hence in the span, and so does m. For the last statement, write M as a quotient of a free module; the kernel is free. □

Proposition 15.8.6. *Let M, N be R-modules. There is a bijection between $\operatorname{Ext}^1_R(M,N)$ and the set of equivalence classes of short exact sequences $0 \to N \to E \to M \to 0$, where two sequences are equivalent if there is an isomorphism of the middle terms compatible with the given maps; the zero element corresponds to the split sequence.*

Proof. Choose $0 \to K \xrightarrow{j} P \to M \to 0$ with P projective. By Theorem 15.8.2 and the long exact sequence, $\operatorname{Ext}^1(M,N) = \operatorname{coker}(\operatorname{Hom}(P,N) \to \operatorname{Hom}(K,N))$. Given an extension $0 \to N \to E \xrightarrow{q} M \to 0$, lift $P \to M$ to $\beta\colon P \to E$; then βj lands in N, and its class $\theta(E)$ does not depend on β (two lifts differ by a map $P \to N$). Conversely, given $\alpha\colon K \to N$, let E_α be the pushout of $N \xleftarrow{\alpha} K \xrightarrow{j} P$, that is, $(N \oplus P)/\{(\alpha(k), -j(k)) : k \in K\}$; it sits in an exact sequence $0 \to N \to E_\alpha \to M \to 0$, and α and $\alpha + \gamma j$ ($\gamma\colon P \to N$) give equivalent extensions via $E_\alpha \to E_{\alpha+\gamma j}, (n,p) \mapsto (n-\gamma(p), p)$, which maps the relation $(\alpha(k), -j(k))$ to $((\alpha+\gamma j)(k), -j(k))$. The lift $p \mapsto (0,p)$ of $P \to M$ to E_α restricts on K to $k \mapsto (0, j(k)) = (\alpha(k), 0)$, so $\theta(E_\alpha)$ is the class of α. For an extension E with lift β, the map $E_{\beta j} \to E$, $(n,p) \mapsto n + \beta(p)$, is well defined and an equivalence by the five lemma. Hence the constructions are inverse. The split extension admits a lift with $\beta j = 0$. □

Example 15.8.7. Let p be a prime. By Proposition 15.8.6, computed with the resolution $0 \to p\mathbb{Z} \xrightarrow{j} \mathbb{Z} \to \mathbb{Z}/p \to 0$: every $f\colon \mathbb{Z} \to \mathbb{Z}/p$ vanishes on $p\mathbb{Z}$, so $\operatorname{Ext}^1_{\mathbb{Z}}(\mathbb{Z}/p, \mathbb{Z}/p) = \operatorname{Hom}(p\mathbb{Z}, \mathbb{Z}/p) \cong \mathbb{Z}/p$, via $\alpha \mapsto a = \alpha(p)$. For $a = 0$ the extension is split, $E = \mathbb{Z}/p \oplus \mathbb{Z}/p$. For $a \neq 0$ the pushout is $E_\alpha = (\mathbb{Z}/p \oplus \mathbb{Z})/\langle (a, -p) \rangle$, in which $(0,1)$ has order p^2: if $m(0,1) = k(a,-p)$, then $ka \equiv 0 \pmod p$ forces $p \mid k$ and $p^2 \mid m$. So $E_\alpha \cong \mathbb{Z}/p^2$, with $\mathbb{Z}/p$ embedded by $n \mapsto na^{-1}p$. The $p-1$ nonzero classes thus give pairwise inequivalent extensions whose middle terms are all isomorphic to $\mathbb{Z}/p^2$: equivalence of extensions remembers the maps, not only the middle group.

Counterexample 15.8.8. Projective, flat and injective are different conditions, already for abelian groups.

1. $\mathbb{Q}$ is flat, since $\mathbb{Q} = S^{-1}\mathbb{Z}$ with $S = \mathbb{Z} \setminus \{0\}$ (Proposition 14.3.2(2)), and injective, since it is divisible (Theorem 15.5.4). It is not projective: a projective abelian group is a direct summand, hence a subgroup, of a free group, hence free (Propositions 15.5.2 and 15.8.5); but $\operatorname{Hom}(\mathbb{Q}, \mathbb{Z}) = 0$, because the image of 1 under a homomorphism $\mathbb{Q} \to \mathbb{Z}$ is divisible by every $n \geq 1$ in $\mathbb{Z}$, while a nonzero free group has a nonzero coordinate map to $\mathbb{Z}$.

2. $\mathbb{Z}$ is projective, hence flat, but not injective, as it is not divisible.

3. $\mathbb{Z}/n$ for $n \geq 2$ is none of the three: it is not flat, since $\operatorname{Tor}_1(\mathbb{Z}/n, \mathbb{Z}/n) = \mathbb{Z}/n \neq 0$ (Example 15.8.3 and Proposition 15.8.4), hence not projective, and it is not divisible, hence not injective.

15.9 Künneth and universal coefficient theorems

In this section R is a principal ideal domain and we use chain complexes of R-modules. The tensor product of chain complexes is $(C \otimes D)_n = \bigoplus_{p+q=n} C_p \otimes D_q$ with $d(x \otimes y) = dx \otimes y + (-1)^p x \otimes dy$ for $x \in C_p$, and $\operatorname{Hom}(C, M)$ is the cochain complex $\operatorname{Hom}(C_n, M)$ with $(d\varphi)(x) = (-1)^{n+1}\varphi(dx)$ for $\varphi \in \operatorname{Hom}(C_n, M)$.

Theorem 15.9.1 (Künneth formula)**.** *Let C be a chain complex of free R-modules and D any chain complex. For every n there is a natural short exact sequence*

$$0 \to \bigoplus_{p+q=n} H_p(C) \otimes H_q(D) \to H_n(C \otimes D) \to \bigoplus_{p+q=n-1} \operatorname{Tor}_1^R(H_p(C), H_q(D)) \to 0,$$

where the first map sends $[x] \otimes [y]$ to $[x \otimes y]$. If D is also a complex of free modules, the sequence splits (non-naturally).

Proof. Let $Z_p = \ker d_p$ and $B_p = \operatorname{im} d_{p+1} \subseteq C_p$; they are free by Proposition 15.8.5, hence flat. Regard Z and B as complexes with zero differential, and let B' be the complex with $B'_p = B_{p-1}$ and zero differential. The sequences $0 \to Z_p \to C_p \xrightarrow{d} B_{p-1} \to 0$ form a short exact sequence of complexes $0 \to Z \to C \to B' \to 0$, split in each degree since B_{p-1} is free; so it stays exact after tensoring with D. As Z and B are flat with zero differential, $H_n(Z \otimes D) = \bigoplus Z_p \otimes H_q(D)$ and similarly for B. The long exact sequence reads

$$\cdots \to \bigoplus_{p+q=n} B_p \otimes H_q(D) \xrightarrow{\partial} \bigoplus_{p+q=n} Z_p \otimes H_q(D) \to H_n(C \otimes D) \to \bigoplus_{p+q=n-1} B_p \otimes H_q(D) \xrightarrow{\partial} \cdots,$$

and computing the connecting map with Theorem 15.4.3 shows that ∂ is induced by the inclusions $B_p \to Z_p$ (a class $b \otimes [y]$ lifts to $c \otimes y$ with $dc = b$, and $d(c \otimes y) = b \otimes y$). Hence $H_n(C \otimes D)$ is an extension of $\ker(\partial)$ in degree $n-1$ by $\operatorname{coker}(\partial)$ in degree n. Since $0 \to B_p \to Z_p \to H_p(C) \to 0$ is a free resolution, $\operatorname{coker}(B_p \otimes H_q(D) \to Z_p \otimes H_q(D)) = H_p(C) \otimes H_q(D)$ and $\ker = \operatorname{Tor}_1(H_p(C), H_q(D))$, by right exactness of $\otimes$ and Theorem 15.8.2.

If D is free as well, choose retractions $r_C \colon C_p \to Z_p$ (which exist since B_{p-1} is free) and r_D. The composites $C_p \to Z_p \to H_p(C)$ form a morphism of complexes $C \to H(C)$ (to the complex with zero differential), since $r_C(dx) = dx \in B_p$ maps to 0; similarly $D \to H(D)$. Their tensor product induces $H_n(C \otimes D) \to \bigoplus H_p(C) \otimes H_q(D)$, which is a left inverse of the first map. □

Theorem 15.9.2 (Universal coefficient theorem)**.** *Let C be a chain complex of free R-modules and M an R-module. There is a natural short exact sequence*

$$0 \to \operatorname{Ext}^1_R(H_{n-1}(C), M) \to H^n(\operatorname{Hom}(C, M)) \to \operatorname{Hom}_R(H_n(C), M) \to 0,$$

where the second map sends the class of a cocycle φ to its restriction to cycles. It splits non-naturally.

Proof. Apply $\operatorname{Hom}(-, M)$ to the degreewise split sequence $0 \to Z \to C \to B' \to 0$ of the previous proof. As Z and B have zero differential, the long exact sequence becomes $\cdots \to \operatorname{Hom}(B_{n-1}, M) \to H^n(\operatorname{Hom}(C, M)) \to \operatorname{Hom}(Z_n, M) \xrightarrow{\partial} \operatorname{Hom}(B_n, M) \to \cdots$, where ∂ is restriction along $B_n \subseteq Z_n$ (up to sign). From the free resolution $0 \to B_n \to Z_n \to H_n(C) \to 0$ we get $\ker(\partial) = \operatorname{Hom}(H_n(C), M)$ and $\operatorname{coker}(\operatorname{Hom}(Z_{n-1}, M) \to \operatorname{Hom}(B_{n-1}, M)) = \operatorname{Ext}^1(H_{n-1}(C), M)$, which gives the sequence. A splitting is obtained from a retraction $r \colon C_n \to Z_n$: a homomorphism $H_n(C) \to M$ composed with $C_n \to Z_n \to H_n(C)$ is a cocycle. □

Example 15.9.3. Let C be the complex $\cdots \to 0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to 0$ in degrees 1 and 0, so $H_0 = \mathbb{Z}/2\mathbb{Z}$ and $H_1 = 0$. Then $\operatorname{Hom}(C, \mathbb{Z})$ is $\mathbb{Z} \xrightarrow{\pm 2} \mathbb{Z}$ in degrees 0 and 1, with $H^0 = 0$ and $H^1 = \mathbb{Z}/2\mathbb{Z}$. Indeed $\operatorname{Hom}(H_1, \mathbb{Z}) = 0$ and $\operatorname{Ext}^1(H_0, \mathbb{Z}) = \mathbb{Z}/2\mathbb{Z}$: torsion in homology shifts up one degree in cohomology. This is the algebraic reason why $H^2(\mathbb{RP}^2, \mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$ while $H_2(\mathbb{RP}^2, \mathbb{Z}) = 0$ (Chapter 22).

15.10 Exercises

Exercise 15.10.1. Prove the 3×3 lemma: in a commutative 3×3 diagram of modules with exact columns, if two of the rows are short exact sequences, so is the third.

Exercise 15.10.2. Let $0 \to A^\bullet \xrightarrow{f} B^\bullet \xrightarrow{g} C^\bullet \to 0$ be a short exact sequence of complexes of modules. Prove Theorem 15.4.3 directly: show that the recipe of Remark 15.4.4 gives a well defined homomorphism $\delta\colon H^n(C) \to H^{n+1}(A)$, and that the long sequence is exact at $H^n(B)$, at $H^n(C)$ and at $H^{n+1}(A)$.

Solution. *a is a cocycle:* $f(d(a)) = d(f(a)) = d(d(b)) = 0$ and f is injective. *Independence of b:* another preimage of c is $b + f(a')$ with $a' \in A^n$, since $\ker g = \operatorname{im} f$; it gives $d(b) + f(d(a'))$, hence $a + d(a')$, which has the same class. *Independence of c in its class:* for $c + d(c')$, write $c' = g(b')$ and use the preimage $b + d(b')$, which gives the same $d(b)$ and the same a. So δ is well defined, and it is additive because sums of choices are choices for sums.

Exactness at $H^n(B)$. $g_* f_* = (gf)_* = 0$. If b is a cocycle with $g_*[b] = 0$, then $g(b) = d(c')$ with $c' = g(b')$, so $g(b - d(b')) = 0$ and $b - d(b') = f(a)$ for some a; then $f(d(a)) = d(b) = 0$, so a is a cocycle and $[b] = [b - d(b')] = f_*[a]$.

Exactness at $H^n(C)$. If $c = g(b)$ with b a cocycle, use this b: $d(b) = 0$, so $\delta[c] = 0$. Conversely, if $\delta[c] = 0$, then $a = d(a')$ and $b - f(a')$ is a cocycle, since $d(b - f(a')) = f(a) - f(d(a')) = 0$, with $g(b - f(a')) = c$; so $[c] \in \operatorname{im} g_*$.

Exactness at $H^{n+1}(A)$. $f_*\delta[c] = [f(a)] = [d(b)] = 0$. Conversely, if a is a cocycle with $f(a) = d(b)$ for some b, then $c = g(b)$ is a cocycle, since $d(c) = g(d(b)) = g(f(a)) = 0$, and by construction $\delta[c] = [a]$. □

Exercise 15.10.3. Show that $\operatorname{Ext}^1_{\mathbb{Z}}(\mathbb{Q}, \mathbb{Z}) \neq 0$. (Hint: use $0 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 0$.)

Exercise 15.10.4. Let R be a PID. Show that an R-module is flat if and only if it is torsion-free.

Exercise 15.10.5. Let $f : A^\bullet \to B^\bullet$ be a morphism of complexes. Show that f is homotopic to zero if and only if the sequence $0 \to B \to \operatorname{Cone}(f) \to A[1] \to 0$ splits as a sequence of complexes.

Exercise 15.10.6. Show that an abelian group is injective if and only if $\operatorname{Ext}^1_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, A) = 0$ for all $n \geq 1$.

Solution. By Example 15.8.3, $\operatorname{Ext}^1(\mathbb{Z}/n\mathbb{Z}, A) = A/nA$, which vanishes for all n iff A is divisible, iff A is injective by Theorem 15.5.4. □

Chapter 16

Spectral Sequences

16.1 Introduction

A spectral sequence is a bookkeeping device for computing the cohomology of a filtered complex from the cohomology of its graded pieces, in a sequence of successive approximations. This chapter constructs the spectral sequence of a filtered complex with complete proofs, derives the two spectral sequences of a double complex, and proves the Grothendieck spectral sequence of a composition of functors. Later chapters use the Leray spectral sequence (Chapter 26), the Frölicher spectral sequence (Chapter 46) and the weight and Hodge spectral sequences of mixed Hodge theory (Chapter 74).

References are [Wei94, Chapter 5] and [McC01]. As in Chapter 15, we argue with elements; by Remark 15.2.5 the results hold in every abelian category.

Prerequisites. Chapter 15 (Homological Algebra).

On the way to the Hodge conjecture. The direct route uses the spectral sequence of a filtered complex and of a double complex, and the Grothendieck spectral sequence (Sections 16.3, 16.4, 16.6). Exact couples (Section 16.5) can be skipped.

16.2 Spectral sequences

Definition 16.2.1. A (cohomological) *spectral sequence* starting at page r_0 consists of objects $E_r^{p,q}$ for $p, q \in \mathbb{Z}$ and $r \geq r_0$, morphisms $d_r \colon E_r^{p,q} \to E_r^{p+r,q-r+1}$ with $d_r \circ d_r = 0$, and isomorphisms $E_{r+1}^{p,q} \cong \ker(d_r)/\mathrm{im}(d_r)$ at $E_r^{p,q}$. The object $E_r = \bigoplus_{p,q} E_r^{p,q}$ is the r-th *page*, and $p+q$ is the *total degree*. It is a *first-quadrant* spectral sequence if $E_{r_0}^{p,q} = 0$ unless $p, q \geq 0$.

Lemma 16.2.2. *In a first-quadrant spectral sequence $E_r^{p,q} = 0$ unless $p, q \geq 0$, for all r, and $E_r^{p,q} = E_{r+1}^{p,q}$ whenever $r > \max(p, q+1)$. The common value is denoted $E_\infty^{p,q}$.*

Proof. The first claim holds because $E_{r+1}^{p,q}$ is a subquotient of $E_r^{p,q}$. For $r > p$ the source $E_r^{p-r,q+r-1}$ of the incoming differential has negative first index, and for $r > q+1$ the target $E_r^{p+r,q-r+1}$ of the outgoing differential has negative second index; so both differentials vanish. □

Definition 16.2.3. A first-quadrant spectral sequence *converges* to objects H^n, written $E_{r_0}^{p,q} \Rightarrow H^{p+q}$, if each H^n has a finite decreasing filtration $H^n = F^0H^n \supseteq F^1H^n \supseteq \cdots \supseteq F^{n+1}H^n = 0$ with isomorphisms $E_\infty^{p,q} \cong F^pH^{p+q}/F^{p+1}H^{p+q}$. The spectral sequence *degenerates* at page r if $d_s = 0$ for all $s \geq r$, so that $E_r = E_\infty$.

Proposition 16.2.4. *Let $E_2^{p,q} \Rightarrow H^{p+q}$ be a convergent first-quadrant spectral sequence.*

1. *There are* edge maps $E_2^{n,0} \to H^n$ *and* $H^n \to E_2^{0,n}$*: the first is the composite* $E_2^{n,0} \twoheadrightarrow E_\infty^{n,0} = F^nH^n \hookrightarrow H^n$*, the second* $H^n \twoheadrightarrow H^n/F^1H^n = E_\infty^{0,n} \hookrightarrow E_2^{0,n}$.

2. *(Five-term exact sequence) The sequence* $0 \to E_2^{1,0} \to H^1 \to E_2^{0,1} \xrightarrow{d_2} E_2^{2,0} \to H^2$ *is exact.*

3. *If* $E_2^{p,q} = 0$ *for* $q \neq 0$*, then* $H^n \cong E_2^{n,0}$*. If* $E_2^{p,q} = 0$ *for* $p \neq 0$*, then* $H^n \cong E_2^{0,n}$.

Proof. (1) Since nothing is in negative degrees, $E_{r+1}^{n,0}$ is a quotient of $E_r^{n,0}$ (no outgoing differential lands in $q < 0$) and $E_{r+1}^{0,n}$ a subobject of $E_r^{0,n}$ (no incoming differential starts at $p < 0$). Also $F^{n+1}H^n = 0$, so $E_\infty^{n,0} = F^nH^n$, and $F^0H^n = H^n$, so $E_\infty^{0,n} = H^n/F^1H^n$. (2) In total degree 1, H^1 has the filtration $0 \subseteq F^1H^1 \subseteq H^1$ with $F^1H^1 = E_\infty^{1,0} = E_2^{1,0}$ (no differential reaches or leaves $E_r^{1,0}$ nontrivially: incoming would start at $p = 1 - r < 0$, outgoing lands at $q = 1 - r < 0$) and $H^1/F^1H^1 = E_\infty^{0,1} = \ker(d_2 \colon E_2^{0,1} \to E_2^{2,0})$ (for $r \geq 3$ all differentials at $(0,1)$ vanish). This gives exactness at $E_2^{1,0}$, H^1 and $E_2^{0,1}$. Next $E_\infty^{2,0} = E_3^{2,0} = E_2^{2,0}/\mathrm{im}(d_2)$, and it injects into H^2 as F^2H^2; so the kernel of $E_2^{2,0} \to H^2$ is $\mathrm{im}(d_2)$. (3) All but one of the graded pieces $E_\infty^{p,n-p}$ of H^n vanish, and all differentials vanish because either the source or the target is zero. □

Proposition 16.2.5. *Let* $E_2^{p,q} \Rightarrow H^{p+q}$ *be a convergent first-quadrant spectral sequence with* $E_2^{p,q} = 0$ *unless* $q \in \{0, s\}$*, for some* $s \geq 1$*. Then there is a long exact sequence*

$$\cdots \to E_2^{n,0} \to H^n \to E_2^{n-s,s} \xrightarrow{d_{s+1}} E_2^{n+1,0} \to H^{n+1} \to \cdots.$$

Proof. The only possibly nonzero differentials are $d_{s+1} \colon E_{s+1}^{p,s} \to E_{s+1}^{p+s+1,0}$, and $E_{s+1} = E_2$. So $E_\infty^{n,0} = \mathrm{coker}(d_{s+1} \colon E_2^{n-s-1,s} \to E_2^{n,0})$ and $E_\infty^{n-s,s} = \ker(d_{s+1} \colon E_2^{n-s,s} \to E_2^{n+1,0})$, and H^n is an extension $0 \to E_\infty^{n,0} \to H^n \to E_\infty^{n-s,s} \to 0$. Splicing these sequences gives the claim. □

Proposition 16.2.6. *Let* E *be a spectral sequence of finite-dimensional vector spaces over a field, with only finitely many nonzero* $E_{r_0}^{p,q}$*. Then* $\chi(E_r) = \sum_{p,q}(-1)^{p+q} \dim E_r^{p,q}$ *does not depend on* r*, and if* $E_{r_0}^{p,q} \Rightarrow H^{p+q}$ *converges, then* $\chi(E_{r_0}) = \sum_n (-1)^n \dim H^n$*. In particular* $\dim H^n \leq \sum_{p+q=n} \dim E_r^{p,q}$ *for every* r.

Proof. Grading E_r by total degree $n = p + q$, the differential d_r raises n by one, so (E_r, d_r) is a finite complex of finite-dimensional spaces with cohomology E_{r+1}. For such a complex $C^\bullet$, rank–nullity gives $\dim C^n = \dim Z^n + \dim B^{n+1}$ and $\dim H^n = \dim Z^n - \dim B^n$, so $\sum_n (-1)^n \dim C^n = \sum_n (-1)^n \dim H^n$. Hence $\chi(E_{r+1}) = \chi(E_r)$. Only finitely many positions are nonzero, so the pages stabilise, and convergence gives $\dim H^n = \sum_p \dim E_\infty^{p,n-p}$. The inequality holds because each $E_\infty^{p,q}$ is a subquotient of $E_r^{p,q}$. □

Counterexample 16.2.7. The limit of a spectral sequence determines the abutment only up to extensions. Let K and K' be the complexes concentrated in degree 0, with zero differential, given by $K^0 = \mathbb{Z}/4$ with the filtration $F^0 = \mathbb{Z}/4 \supseteq F^1 = 2\mathbb{Z}/4 \supseteq F^2 = 0$, and $K'^0 = \mathbb{Z}/2 \oplus \mathbb{Z}/2$ with $F^0 = K'^0 \supseteq F^1 = 0 \oplus \mathbb{Z}/2 \supseteq F^2 = 0$. In both cases all differentials vanish and the spectral sequence of the filtered complex (Section 16.3) has $E_0^{0,0} = \mathbb{Z}/2$ and $E_0^{1,-1} = \mathbb{Z}/2$ on every page. The spectral sequences are isomorphic, but the abutments $\mathbb{Z}/4$ and $\mathbb{Z}/2 \oplus \mathbb{Z}/2$ are not. Over a field this cannot happen, since every extension of vector spaces splits and $H^n \cong \bigoplus_p E_\infty^{p,n-p}$.

16.3 The spectral sequence of a filtered complex

Definition 16.3.1. A *filtered complex* is a complex $K^\bullet$ with subcomplexes $\cdots \supseteq F^pK \supseteq F^{p+1}K \supseteq \cdots$. The filtration is *finite in each degree* if for every n there are $a \le b$ with $F^aK^n = K^n$ and $F^bK^n = 0$. The *associated graded* complexes are $\mathrm{gr}^pK = F^pK/F^{p+1}K$, and the induced filtration on cohomology is $F^pH^n(K) = \mathrm{im}(H^n(F^pK) \to H^n(K))$.

Definition 16.3.2. For a filtered complex K we abbreviate $F^p = F^pK$ and, for $r \ge 0$,

$$Z_r^p = F^p \cap d^{-1}(F^{p+r}), \qquad B_r^p = F^p \cap d(F^{p-r+1}), \qquad E_r^p = Z_r^p/(B_r^p + Z_{r-1}^{p+1}),$$

with the convention $Z_{-1}^{p+1} = F^{p+1}$. These are graded by the degree of K, and we write $E_r^{p,q}$ for the part of E_r^p in degree $p+q$. Let $d_r\colon E_r^p \to E_r^{p+r}$ be induced by d.

Lemma 16.3.3. *The inclusions $B_r^p \subseteq Z_r^p$ and $Z_{r-1}^{p+1} \subseteq Z_r^p$ hold, so E_r^p is defined, and d_r is a well-defined morphism with $d_r^2 = 0$, of bidegree $(r, 1-r)$. Moreover $E_0^p = \mathrm{gr}^pK$ with d_0 induced by d, and $E_1^{p,q} = H^{p+q}(\mathrm{gr}^pK)$.*

Proof. Elements of B_r^p are boundaries, hence cycles; and $x \in F^{p+1}$ with $dx \in F^{p+r}$ lies in Z_r^p. If $x \in Z_r^p$ then $dx \in F^{p+r}$ and $d(dx) = 0$, so $dx \in Z_r^{p+r}$. We must check that d maps $B_r^p + Z_{r-1}^{p+1}$ into $B_r^{p+r} + Z_{r-1}^{p+r+1}$: $d(B_r^p) = 0$, and for $x \in Z_{r-1}^{p+1}$ we have $dx \in F^{p+r} \cap d(F^{p+1}) = B_r^{p+r}$. Clearly $d_r^2 = 0$. For $r = 0$: $Z_0^p = F^p$ and $B_0^p = d(F^{p+1}) \subseteq F^{p+1}$, so $E_0^p = F^p/F^{p+1}$. For $r = 1$: Z_1^p consists of the elements of F^p whose image in gr^p is a cocycle, $Z_0^{p+1} = F^{p+1}$ and $B_1^p = d(F^p)$, so $E_1^p = Z_1^p/(d(F^p) + F^{p+1})$ is the cohomology of gr^pK. □

Theorem 16.3.4. *For every filtered complex, the objects $E_r^{p,q}$ and differentials d_r, $r \ge 0$, form a spectral sequence: $H(E_r, d_r) \cong E_{r+1}$. If the filtration is finite in each degree, then for fixed (p, q) and all sufficiently large r, $E_r^{p,q} = E_\infty^{p,q}$ with*

$$E_\infty^{p,q} \cong F^pH^{p+q}(K)/F^{p+1}H^{p+q}(K).$$

In particular, if $F^0K = K$ and $F^{n+1}K^n = 0$ for all n, the spectral sequence is first-quadrant (from E_1 on, since $E_1^{p,q}$ vanishes for $p < 0$ or $q < 0$) and $E_1^{p,q} = H^{p+q}(\mathrm{gr}^pK) \Rightarrow H^{p+q}(K)$.

Proof. Kernel of d_r at E_r^p. Let $x \in Z_r^p$ with $dx \in B_r^{p+r} + Z_{r-1}^{p+r+1}$, say $dx = dy + z$ with $y \in F^{p+1}$, $dy \in F^{p+r}$ and $z \in F^{p+r+1}$. Then $y \in Z_{r-1}^{p+1}$, and $x - y \in F^p$ with $d(x-y) = z \in F^{p+r+1}$, so $x - y \in Z_{r+1}^p$. Conversely, Z_{r+1}^p maps into the kernel, since $dx \in F^{p+r+1}$ and $d(dx) = 0$ give $dx \in Z_{r-1}^{p+r+1}$. Hence the kernel is $(Z_{r+1}^p + Z_{r-1}^{p+1})/(B_r^p + Z_{r-1}^{p+1})$.

Image of d_r in E_r^p. It consists of the classes of dx with $x \in Z_r^{p-r}$, that is of the elements of $F^p \cap d(F^{p-r}) = B_{r+1}^p$. Since $B_r^p \subseteq B_{r+1}^p$, the image is $(B_{r+1}^p + Z_{r-1}^{p+1})/(B_r^p + Z_{r-1}^{p+1})$.

Cohomology. Therefore $H(E_r)^p = (Z_{r+1}^p + Z_{r-1}^{p+1})/(B_{r+1}^p + Z_{r-1}^{p+1})$. The map $Z_{r+1}^p \to H(E_r)^p$ is surjective, with kernel $Z_{r+1}^p \cap (B_{r+1}^p + Z_{r-1}^{p+1}) = B_{r+1}^p + (Z_{r+1}^p \cap Z_{r-1}^{p+1})$ (as $B_{r+1}^p \subseteq Z_{r+1}^p$). Now $Z_{r+1}^p \cap Z_{r-1}^{p+1} = F^{p+1} \cap d^{-1}(F^{p+r+1}) = Z_r^{p+1}$. So $H(E_r)^p \cong Z_{r+1}^p/(B_{r+1}^p + Z_r^{p+1}) = E_{r+1}^p$.

Convergence. Fix n and p and let Z, B denote the cocycles and coboundaries of K. If the filtration is finite in degrees $n-1$, n and $n+1$, then for large r we have $F^{p+r}K^{n+1} = 0$ and $F^{p-r+1}K^{n-1} = K^{n-1}$, so in degree n: $Z_r^p = F^p \cap Z$, $Z_{r-1}^{p+1} = F^{p+1} \cap Z$ and $B_r^p = F^p \cap B$. Hence $E_\infty^p = (F^p \cap Z)/((F^p \cap B) + (F^{p+1} \cap Z))$. On the other hand $F^pH^n = (F^p \cap Z + B)/B$, and

$$\frac{F^pH^n}{F^{p+1}H^n} \cong \frac{F^p \cap Z}{(F^p \cap Z) \cap (F^{p+1} \cap Z + B)} = \frac{F^p \cap Z}{F^{p+1} \cap Z + F^p \cap B},$$

using the modular law. For the last statement, $\mathrm{gr}^pK = 0$ for $p < 0$ and $\mathrm{gr}^pK^n = 0$ for $p > n$, so $E_1^{p,q} = 0$ unless $p \ge 0$ and $q \ge 0$, and F^pH^n runs from H^n to 0. □

16.4 Double complexes

Theorem 16.4.1. *Let C be a first-quadrant double complex (Definition 15.7.1) and $T = \mathrm{Tot}(C)$. There are two convergent first-quadrant spectral sequences*

$$ {}^{I}E_2^{p,q} = H_h^p(H_v^q(C)) \Rightarrow H^{p+q}(T), \qquad {}^{II}E_2^{p,q} = H_v^p(H_h^q(C)) \Rightarrow H^{p+q}(T), $$

where $H_v^q(C)$ is the cohomology of the columns (a complex in p via d_h), and $H_h^q(C)$ that of the rows (a complex in the other index via d_v).

Proof. Filter T by columns: ${}^{I}F^pT^n = \bigoplus_{i \geq p} C^{i,n-i}$. These are subcomplexes, $F^0T = T$ and $F^{n+1}T^n = 0$. The graded piece gr^pT is the column $C^{p,\bullet}$ (shifted by p) with differential $\pm d_v$, so ${}^{I}E_1^{p,q} = H_v^q(C^{p,\bullet})$ by Theorem 16.3.4. The differential d_1 is the connecting map of $0 \to \mathrm{gr}^{p+1} \to F^p/F^{p+2} \to \mathrm{gr}^p \to 0$; a cocycle $x \in C^{p,q}$ of d_v lifts to itself, and its total differential is $d_h x \in C^{p+1,q}$, so $d_1 = H_v^q(d_h)$ and ${}^{I}E_2^{p,q} = H_h^p(H_v^q(C))$. Convergence follows from Theorem 16.3.4. Filtering by rows, ${}^{II}F^pT^n = \bigoplus_{j \geq p} C^{n-j,j}$, gives the other spectral sequence in the same way. □

Example 16.4.2. If the rows of C are exact in positive degrees, with kernel complex $K^\bullet$ in column 0, then ${}^{II}E_1^{p,q} = H_h^q(C^{\bullet,p})$ vanishes for $q > 0$ and equals K^p for $q = 0$. So ${}^{II}E_2^{p,0} = H^p(K)$, all other terms vanish, and $H^n(T) \cong H^n(K)$ by Proposition 16.2.4(3). This recovers Lemma 15.7.2.

16.5 Exact couples

Definition 16.5.1. An *exact couple* consists of objects D, E and morphisms $i\colon D \to D$, $j\colon D \to E$, $k\colon E \to D$ such that the triangle $D \xrightarrow{i} D \xrightarrow{j} E \xrightarrow{k} D$ is exact at each vertex. Put $d = jk\colon E \to E$; then $d^2 = j(kj)k = 0$.

Proposition 16.5.2. *Given an exact couple, let $D' = i(D)$, $E' = \ker d / \operatorname{im} d$, $i' = i|_{D'}$, $j'(i(x)) = [j(x)]$ and $k'([e]) = k(e)$. Then (D', E', i', j', k') is an exact couple, the* derived couple. *Iterating gives a spectral sequence $E^{(r)}$ with differentials $d^{(r)} = j^{(r)}k^{(r)}$.*

Proof. j' is well defined: if $i(x) = i(x')$ then $x - x' = k(e)$ and $j(x - x') = jk(e) = d(e)$; and $j(x)$ is a d-cocycle since $dj(x) = jkj(x) = 0$. k' is well defined: if $e \in \ker d$ then $jk(e) = 0$ so $k(e) \in \ker j = \operatorname{im} i = D'$, and $k(d(e')) = kjk(e') = 0$. Exactness at D' (between i' and j'): $j'(i(x)) = 0$ iff $j(x) = jk(e)$ iff $x - k(e) \in \ker j = \operatorname{im} i$, iff $i(x) \in i(\operatorname{im} i) + ik(E) = i(D')$ since $ik = 0$. Exactness at E': $k'[e] = 0$ iff $k(e) = 0$ iff $e = j(x)$, iff $[e] = j'(i(x))$. Exactness at the other D' (between k' and i'): $i'(i(x)) = 0$ iff $i(x) \in \ker i = \operatorname{im} k$, iff $i(x) = k(e)$ for some e, which is then a d-cocycle since $jk(e) = ji(x) = 0$; that is, iff $i(x) \in \operatorname{im} k'$. □

Remark 16.5.3. A filtered complex gives an exact couple with $D = \bigoplus_{p,n} H^n(F^pK)$, $E = \bigoplus_{p,n} H^n(\mathrm{gr}^pK)$, i induced by the inclusions $F^{p+1} \subseteq F^p$, and j, k from the long exact sequences of $0 \to F^{p+1} \to F^p \to \mathrm{gr}^p \to 0$. The resulting spectral sequence is the one of Theorem 16.3.4, from E_1 on [Wei94, Section 5.9].

16.6 The Grothendieck spectral sequence

Definition 16.6.1. Let $A^\bullet$ be a complex with $A^n = 0$ for $n < 0$ in an abelian category with enough injectives. A *Cartan–Eilenberg resolution* of A is a first-quadrant double complex

$I^{\bullet,\bullet}$ of injectives with a morphism $A^p \to I^{p,0}$ for each p, such that for every p the columns give injective resolutions $A^p \to I^{p,\bullet}$, $Z^p(A) \to Z_h^p(I)^\bullet$, $B^p(A) \to B_h^p(I)^\bullet$ and $H^p(A) \to H_h^p(I)^\bullet$, where Z_h, B_h, H_h denote horizontal cocycles, coboundaries and cohomology.

Lemma 16.6.2. *Every such complex A has a Cartan–Eilenberg resolution.*

Proof. For each p choose injective resolutions $B^p(A) \to J_B^{p,\bullet}$ and $H^p(A) \to J_H^{p,\bullet}$. The horseshoe lemma (Lemma 15.6.3) applied to $0 \to B^p \to Z^p \to H^p \to 0$ gives a resolution $J_Z^{p,\bullet}$ of Z^p with $J_Z^{p,q} = J_B^{p,q} \oplus J_H^{p,q}$, and applied to $0 \to Z^p \to A^p \to B^{p+1} \to 0$ gives a resolution $I^{p,\bullet}$ of A^p with $I^{p,q} = J_Z^{p,q} \oplus J_B^{p+1,q}$. Define $d_h \colon I^{p,q} \to I^{p+1,q}$ as the composite $I^{p,q} \to J_B^{p+1,q} \to J_Z^{p+1,q} \to I^{p+1,q}$ of the projection and inclusions provided by the horseshoe lemma. Then $d_h^2 = 0$ (the projection $I^{p+1,q} \to J_B^{p+2,q}$ kills $J_Z^{p+1,q}$), d_h commutes with the vertical differentials since all maps involved are morphisms of complexes, and it covers $d \colon A^p \to A^{p+1}$. By construction the horizontal cocycles, coboundaries and cohomology in column p are $J_Z^{p,\bullet}$, $J_B^{p,\bullet}$ and $J_H^{p,\bullet}$. □

Theorem 16.6.3 (Grothendieck spectral sequence)**.** *Let $\mathcal{A}, \mathcal{B}, \mathcal{C}$ be abelian categories, $\mathcal{A}$ and $\mathcal{B}$ with enough injectives, and $F \colon \mathcal{A} \to \mathcal{B}$, $G \colon \mathcal{B} \to \mathcal{C}$ left exact functors such that F maps injective objects to G-acyclic objects. For every $X \in \mathcal{A}$ there is a convergent first-quadrant spectral sequence*

$$E_2^{p,q} = R^pG(R^qF(X)) \Rightarrow R^{p+q}(G \circ F)(X).$$

Proof. Let $X \to A^\bullet$ be an injective resolution in $\mathcal{A}$, and let $I^{\bullet,\bullet}$ be a Cartan–Eilenberg resolution of the complex $F(A^\bullet)$ in $\mathcal{B}$. Consider the double complex $G(I)$ and its total complex T.

First filtration (by columns). For each p, the column $I^{p,\bullet}$ is an injective resolution of the G-acyclic object $F(A^p)$, so $H_v^q(G(I^{p,\bullet})) = R^qG(F(A^p))$ is $G(F(A^p))$ for $q = 0$ and 0 for $q > 0$. So ${}^{I}E_2^{p,q} = 0$ for $q > 0$ and ${}^{I}E_2^{p,0} = H^p(GF(A^\bullet)) = R^p(GF)(X)$, and $H^n(T) \cong R^n(GF)(X)$ by Proposition 16.2.4(3).

Second filtration (by rows). Fix a row index j. In the row $I^{\bullet,j}$ the sequences $0 \to B_h^{q,j} \to Z_h^{q,j} \to H_h^{q,j} \to 0$ and $0 \to Z_h^{q,j} \to I^{q,j} \to B_h^{q+1,j} \to 0$ consist of injective objects (they are terms of injective resolutions), hence split; so G commutes with taking horizontal cocycles, coboundaries and cohomology of this row, and $H_h^q(G(I^{\bullet,j})) = G(H_h^{q,j}(I))$. For fixed q, the column $H_h^{q,\bullet}(I)$ is an injective resolution of $H^q(F(A^\bullet)) = R^qF(X)$. By Theorem 16.4.1, ${}^{II}E_2^{p,q} = H_v^p(H_h^q(G(I))) = H^p(G(H_h^{q,\bullet}(I))) = R^pG(R^qF(X))$, and it converges to $H^{p+q}(T) \cong R^{p+q}(GF)(X)$. □

16.7 Exercises

Exercise 16.7.1. State and prove the analogue of Proposition 16.2.5 for a spectral sequence concentrated in two columns $p \in \{0, s\}$.

Exercise 16.7.2. Let $0 \to A^\bullet \to B^\bullet \to C^\bullet \to 0$ be a short exact sequence of bounded below complexes, viewed as a double complex with three columns. Using both spectral sequences of Theorem 16.4.1 (after shifting so that the double complex is first-quadrant), show that if two of A, B, C are acyclic, then so is the third.

Exercise 16.7.3. Use Theorem 16.4.1 to give a second proof of Theorem 15.8.2.

Exercise 16.7.4. Let $R \to S$ be a homomorphism of commutative rings, M an S-module and N an R-module. Construct a spectral sequence $\operatorname{Tor}_p^S(M, \operatorname{Tor}_q^R(S, N)) \Rightarrow \operatorname{Tor}_{p+q}^R(M, N)$ (homological indexing).

Chapter 17

Derived Categories

17.1 Introduction

The derived category of an abelian category is obtained from complexes by declaring quasi-isomorphisms to be isomorphisms. It is the natural home of derived functors: instead of a sequence of functors R^nF one has a single functor RF on complexes, compositions of derived functors are derived functors of compositions, and hypercohomology of complexes (for instance of the de Rham complex of a manifold) is defined without choices. Filtered derived categories and strict morphisms, discussed at the end, are the framework of Deligne's mixed Hodge theory (Chapter 74).

Some foundational verifications (the octahedral axiom, and the construction of localisations by roofs) are quoted from [Wei94, Chapter 10], [GM03, Chapter III] and [KS06]; everything used about derived functors is proved.

Prerequisites. Chapter 6 (Categories), Chapter 15 (Homological Algebra) and Chapter 16 (Spectral Sequences).

On the way to the Hodge conjecture. Only the homotopy category, the derived category and injective resolutions of complexes are needed, for hypercohomology. t-structures and filtered complexes (Sections 17.5, 17.6) are used for mixed Hodge structures and can be postponed.

Throughout, $\mathcal{A}$ is an abelian category, complexes are as in Definition 15.3.1, and we argue with elements as justified by Remark 15.2.5.

17.2 The homotopy category

Definition 17.2.1. The *homotopy category* $K(\mathcal{A})$ has the complexes as objects and homotopy classes of morphisms of complexes (Definition 15.3.3) as morphisms. $K^+(\mathcal{A})$ is its full subcategory of bounded below complexes. The *shift* $X \mapsto X[1]$ is an automorphism of $K(\mathcal{A})$. A *distinguished triangle* in $K(\mathcal{A})$ is a diagram $X \to Y \to Z \to X[1]$ isomorphic (in $K(\mathcal{A})$) to one of the form $X \xrightarrow{f} Y \xrightarrow{i} \operatorname{Cone}(f) \xrightarrow{p} X[1]$, with i and p the maps of Proposition 15.4.5.

Remark 17.2.2. Homotopy is compatible with sums and compositions, so $K(\mathcal{A})$ is an additive category, and cohomology $H^n\colon K(\mathcal{A}) \to \mathcal{A}$ is a well-defined functor by Lemma 15.3.4.

Definition 17.2.3. A *triangulated category* is an additive category $\mathcal{T}$ with an additive automorphism $X \mapsto X[1]$ and a class of *distinguished triangles* $X \to Y \to Z \to X[1]$ such that:

(TR1) $X \xrightarrow{\mathrm{id}} X \to 0 \to X[1]$ is distinguished; triangles isomorphic to distinguished ones are distinguished; every morphism $X \to Y$ is the first morphism of a distinguished triangle.

(TR2) $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$ is distinguished if and only if $Y \xrightarrow{g} Z \xrightarrow{h} X[1] \xrightarrow{-f[1]} Y[1]$ is.

(TR3) Given distinguished triangles $X \to Y \to Z \to X[1]$ and $X' \to Y' \to Z' \to X'[1]$ and morphisms $u\colon X \to X'$, $v\colon Y \to Y'$ making the first square commute, there is $w\colon Z \to Z'$ making the whole diagram commute.

(TR4) (Octahedral axiom) For composable $X \xrightarrow{f} Y \xrightarrow{g} Z$ and distinguished triangles on f, g and gf with third vertices Z', X', Y', there is a distinguished triangle $Z' \to Y' \to X' \to Z'[1]$ compatible with the given morphisms.

An additive functor between triangulated categories commuting with the shifts and preserving distinguished triangles is *exact* (or triangulated).

Theorem 17.2.4. *$K(\mathcal{A})$ and $K^+(\mathcal{A})$ are triangulated categories.*

Sketch of proof. (TR1): $\mathrm{Cone}(\mathrm{id}_X)$ is contractible, with contracting homotopy $(a,b) \mapsto (b,0)$, so it is isomorphic to 0 in $K(\mathcal{A})$; the other two parts hold by definition. (TR3): if h is a homotopy with $vf - f'u = dh + hd$, then $(a,b) \mapsto (u(a), v(b) + h(a))$ is a morphism of complexes $\mathrm{Cone}(f) \to \mathrm{Cone}(f')$ (a direct check using the formula for the differential of the cone in Definition 15.3.5) compatible with the maps of the triangles. The omitted verifications are (TR2), which amounts to an explicit homotopy equivalence $\mathrm{Cone}(i) \simeq X[1]$ for $i\colon Y \to \mathrm{Cone}(f)$, and the octahedral axiom (TR4); see [Wei94, Sections 10.1–10.2]. □

Proposition 17.2.5. *Let $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$ be a distinguished triangle in a triangulated category $\mathcal{T}$ and W an object. Then $gf = 0$, and the sequence $\mathrm{Hom}(W,X) \to \mathrm{Hom}(W,Y) \to \mathrm{Hom}(W,Z)$ is exact; so by (TR2) there is a long exact sequence $\cdots \to \mathrm{Hom}(W,X) \to \mathrm{Hom}(W,Y) \to \mathrm{Hom}(W,Z) \to \mathrm{Hom}(W,X[1]) \to \cdots$. Similarly for $\mathrm{Hom}(-,W)$. For $\mathcal{T} = K(\mathcal{A})$, the functor H^0 sends distinguished triangles to long exact sequences.*

Proof. Apply (TR3) to the triangles $X \xrightarrow{\mathrm{id}} X \to 0 \to X[1]$ and $X \to Y \to Z \to X[1]$ with $u = \mathrm{id}$, $v = f$: the resulting w satisfies $gf = w \circ 0 = 0$. Let $\varphi\colon W \to Y$ with $g\varphi = 0$. By (TR1) and (TR2), the rotated triangles $W \to 0 \to W[1] \xrightarrow{-\mathrm{id}} W[1]$ and $Y \xrightarrow{g} Z \xrightarrow{h} X[1] \xrightarrow{-f[1]} Y[1]$ are distinguished. The square formed by $\varphi\colon W \to Y$ and $0\colon 0 \to Z$ commutes because $g\varphi = 0$, so (TR3) gives $w\colon W[1] \to X[1]$ with $(-f[1]) \circ w = \varphi[1] \circ (-\mathrm{id})$. Then $\psi = w[-1]$ satisfies $f\psi = \varphi$. The dual statement is proved in the same way. For $K(\mathcal{A})$ the last claim follows from the long exact sequence of the cone (Proposition 15.4.5) and invariance under isomorphism. □

17.3 The derived category

Definition 17.3.1. A class S of morphisms in a category C is a *multiplicative system* if it contains the identities and is closed under composition, and:

1. for $s\colon X' \to X$ in S and $f\colon Y \to X$ there are $t\colon Y' \to Y$ in S and $g\colon Y' \to X'$ with $ft = sg$, and dually;
2. if $f, g\colon X \to Y$ and $s\colon Y \to Y'$ in S satisfy $sf = sg$, then $ft = gt$ for some $t\colon X' \to X$ in S, and dually.

Theorem 17.3.2 (Localisation)**.** *Let S be a multiplicative system in C. There is a category $C[S^{-1}]$ with the same objects and a functor $Q\colon C \to C[S^{-1}]$ that is the identity on objects, sends S to*

isomorphisms, and is universal: every functor sending S to isomorphisms factors uniquely through Q. Morphisms $X \to Y$ in $\mathcal{C}[S^{-1}]$ are equivalence classes of roofs $X \xleftarrow{s} X' \xrightarrow{f} Y$ *with $s \in S$, representing $Q(f)Q(s)^{-1}$, and for $f, g\colon X \to Y$ in $\mathcal{C}$ one has $Q(f) = Q(g)$ if and only if $ft = gt$ for some $t \in S$. If $\mathcal{C}$ is additive (triangulated) and S is compatible with the structure, then $\mathcal{C}[S^{-1}]$ is additive (triangulated), with distinguished triangles the images of those of $\mathcal{C}$.*

This is proved in [GM03, Chapter III] and [KS06, Chapter 7]; for the triangulated case see [Wei94, Section 10.3].

Proposition 17.3.3. *The quasi-isomorphisms form a multiplicative system in $K(\mathcal{A})$ and in $K^+(\mathcal{A})$.*

Proof. Identities and composites of quasi-isomorphisms are quasi-isomorphisms. Note that a morphism is a quasi-isomorphism iff its cone is acyclic (Proposition 15.4.5), and by Proposition 17.2.5 the cohomology of the three vertices of a distinguished triangle forms a long exact sequence.

(1) Let $s\colon X' \to X$ be a quasi-isomorphism and $f\colon Y \to X$. Complete s to a triangle $X' \to X \xrightarrow{p} C \to X'[1]$, so C is acyclic, and complete $pf\colon Y \to C$ to a triangle $Y' \xrightarrow{t} Y \xrightarrow{pf} C \to Y'[1]$ (using (TR1) and (TR2)). Then t is a quasi-isomorphism since C is acyclic, and (TR3) applied to the rotated triangles gives $g\colon Y' \to X'$ with $sg = ft$. The dual statement is proved in the same way.

(2) Suppose $s(f - g) = 0$ with $s\colon Y \to Y'$ a quasi-isomorphism. Complete s to a triangle $C[-1] \xrightarrow{k} Y \xrightarrow{s} Y' \to C$ with C acyclic. By Proposition 17.2.5, $f - g = k\varphi$ for some $\varphi\colon X \to C[-1]$. Complete φ to a triangle $X' \xrightarrow{t} X \xrightarrow{\varphi} C[-1] \to X'[1]$; then t is a quasi-isomorphism and $(f - g)t = k\varphi t = 0$. Dually. □

Definition 17.3.4. The *derived category* is $D(\mathcal{A}) = K(\mathcal{A})[\mathrm{Qis}^{-1}]$, and $D^+(\mathcal{A}) = K^+(\mathcal{A})[\mathrm{Qis}^{-1}]$. By Theorem 17.3.2 and Proposition 17.3.3 they are triangulated, H^n factors through them, and a morphism in $D(\mathcal{A})$ is an isomorphism if and only if it induces isomorphisms on all H^n.

Remark 17.3.5. The morphism classes of $D(\mathcal{A})$ need not be small sets for an arbitrary locally small $\mathcal{A}$, since roofs involve all complexes. For $\mathcal{A}$ with enough injectives this problem disappears for $D^+(\mathcal{A})$ by Corollary 17.4.2, which computes morphisms using a single complex of injectives.

17.4 Injective resolutions of complexes

Lemma 17.4.1. *Let X be an acyclic complex and I a bounded below complex of injective objects. Every morphism of complexes $f\colon X \to I$ is homotopic to zero.*

Proof. Let $I^n = 0$ for $n < n_0$; put $h^n = 0\colon X^n \to I^{n-1}$ for $n \le n_0$. Suppose h^k is defined for $k \le n$ with $f^{k-1} = dh^{k-1} + h^k d$ for $k \le n$. Let $g = f^n - dh^n\colon X^n \to I^n$. Then $gd = df^{n-1} - dh^n d = df^{n-1} - d(f^{n-1} - dh^{n-1}) = 0$, so g vanishes on $\mathrm{im}(X^{n-1} \to X^n) = \ker(X^n \to X^{n+1})$. Hence g factors through $X^n/\ker \cong \mathrm{im}(X^n \to X^{n+1}) \subseteq X^{n+1}$ and extends, by injectivity of I^n, to $h^{n+1}\colon X^{n+1} \to I^n$ with $h^{n+1}d = g$, that is, $f^n = dh^n + h^{n+1}d$. □

Corollary 17.4.2. *Let I be a bounded below complex of injectives. For every quasi-isomorphism $s\colon X' \to X$, composition with s is a bijection $\mathrm{Hom}_{K(\mathcal{A})}(X, I) \to \mathrm{Hom}_{K(\mathcal{A})}(X', I)$. Consequently $\mathrm{Hom}_{D(\mathcal{A})}(X, I) = \mathrm{Hom}_{K(\mathcal{A})}(X, I)$, and every quasi-isomorphism $I \to I'$ between bounded below complexes of injectives is a homotopy equivalence.*

Proof. Complete s to a distinguished triangle $X' \to X \to C \to X'[1]$ with C acyclic. By Lemma 17.4.1, $\mathrm{Hom}_K(C, I) = \mathrm{Hom}_K(C[-1], I) = 0$ ($C[-1]$ is also acyclic), and the long exact sequence of Proposition 17.2.5 gives the bijection. For the second statement, we use the description of morphisms in Theorem 17.3.2. The map $Q\colon \mathrm{Hom}_K(X, I) \to \mathrm{Hom}_D(X, I)$ is surjective: a roof $X \xleftarrow{s} X' \xrightarrow{f} I$ has $f = f's$ for some $f'\colon X \to I$, and then $Q(f)Q(s)^{-1} = Q(f')$. It is injective: if $Q(f_1) = Q(f_2)$, then $f_1 t = f_2 t$ for a quasi-isomorphism t, so $f_1 = f_2$ by the bijection just proved. For the last, a quasi-isomorphism $I \to I'$ is an isomorphism in $D(\mathcal{A})$, hence by the second statement an isomorphism in $K(\mathcal{A})$. □

Proposition 17.4.3. *If $\mathcal{A}$ has enough injectives, every bounded below complex X admits a quasi-isomorphism $X \to I$ to a bounded below complex of injectives. Hence $K^+(\mathrm{Inj}\,\mathcal{A}) \to D^+(\mathcal{A})$ is an equivalence of categories.*

Proof. Shifting, assume $X^n = 0$ for $n < 0$. Let $J^{\bullet,\bullet}$ be a Cartan–Eilenberg resolution of X (Lemma 16.6.2) and $I = \mathrm{Tot}(J)$, a bounded below complex of injectives (each I^n is a finite sum). The augmentations $X^p \to J^{p,0}$ define a morphism $X \to I$. For each p the column $0 \to X^p \to J^{p,0} \to J^{p,1} \to \cdots$ is exact, so by Lemma 15.7.2 (applied with the roles of rows and columns exchanged) the map $X \to I$ is a quasi-isomorphism. (The total complex of the transposed double complex is isomorphic to I by the signs $(-1)^{pq}$, and the compatibility of $X^p \to J^{p,0}$ with the differentials holds because the column differential kills the image of X^p.) The functor $K^+(\mathrm{Inj}\,\mathcal{A}) \to D^+(\mathcal{A})$ is fully faithful by Corollary 17.4.2 and essentially surjective by the first statement. □

Definition 17.4.4. Let $\mathcal{A}$ have enough injectives and $F\colon \mathcal{A} \to \mathcal{B}$ be an additive functor to an abelian category. For each bounded below complex X choose a quasi-isomorphism $X \to I_X$ as in Proposition 17.4.3. The *right derived functor* is $RF\colon D^+(\mathcal{A}) \to D^+(\mathcal{B})$, $RF(X) = F(I_X)$ (with F applied termwise), on morphisms via $\mathrm{Hom}_D(X, Y) \cong \mathrm{Hom}_K(I_X, I_Y)$. For $X \in D^+(\mathcal{A})$ and $n \in \mathbb{Z}$, $R^nF(X) = H^n(RF(X))$ is the n-th *hypercohomology* of F at X.

Proposition 17.4.5. *RF is an exact functor of triangulated categories, independent of the choices up to canonical isomorphism. If F is left exact and $X \in \mathcal{A}$ is viewed as a complex in degree 0, then $H^n(RF(X)) = R^nF(X)$ as in Definition 15.6.4. For $X, Y \in \mathcal{A}$ and $n \in \mathbb{Z}$, $\mathrm{Hom}_{D(\mathcal{A})}(X, Y[n]) \cong R^n \mathrm{Hom}(X, -)(Y)$; in particular $\mathrm{Hom}_{D(R\text{-}\mathsf{Mod})}(M, N[n]) \cong \mathrm{Ext}^n_R(M, N)$ for R-modules M, N.*

Proof. Independence of the choices follows from uniqueness of I_X up to unique isomorphism in $K(\mathcal{A})$ (Corollary 17.4.2). For exactness, a distinguished triangle of $D^+(\mathcal{A})$ is isomorphic to one of the form $X \xrightarrow{g} Y \to \mathrm{Cone}(g) \to X[1]$ with g a morphism of bounded below complexes. By Corollary 17.4.2 there is $g_I\colon I_X \to I_Y$ with $g_I \iota_X = \iota_Y g$ in $K(\mathcal{A})$, where ι denotes the resolutions, and (TR3) in $K(\mathcal{A})$ gives a morphism of triangles (ι_X, ι_Y, w) from the triangle of g to that of g_I. By Proposition 17.2.5, the five lemma (Lemma 15.4.2) shows that w is a quasi-isomorphism. So the triangle is isomorphic in $D(\mathcal{A})$ to $I_X \to I_Y \to \mathrm{Cone}(g_I) \to I_X[1]$, whose vertices are bounded below complexes of injectives, and RF sends it to $F(I_X) \to F(I_Y) \to F(\mathrm{Cone}(g_I)) \to F(I_X)[1]$. Since F is additive and applied termwise, $F(\mathrm{Cone}(g_I)) = \mathrm{Cone}(F(g_I))$ with the corresponding maps, so this triangle is distinguished.

For $X \in \mathcal{A}$, an injective resolution is a quasi-isomorphism $X \to I$, so $H^n(RF(X)) = H^n(F(I)) = R^nF(X)$. Finally $\mathrm{Hom}_D(X, Y[n]) = \mathrm{Hom}_K(X, I_Y[n])$ by Corollary 17.4.2. A morphism of complexes $X \to I_Y[n]$ is a morphism $\varphi\colon X \to I_Y^n$ with $d\varphi = 0$, that is, an element of $\ker(\mathrm{Hom}(X, I_Y^n) \to \mathrm{Hom}(X, I_Y^{n+1}))$, and it is homotopic to zero if and only if $\varphi = dh$ for some $h\colon X \to I_Y^{n-1}$. So $\mathrm{Hom}_K(X, I_Y[n]) = H^n(\mathrm{Hom}(X, I_Y)) = R^n \mathrm{Hom}(X, -)(Y)$. For modules this is $\mathrm{Ext}^n_R(M, N)$ by Definition 15.8.1, as R-Mod has enough injectives (Theorem 15.5.4). □

Lemma 17.4.6. *Let $\mathcal{B}$ have enough injectives, $G\colon \mathcal{B} \to \mathcal{C}$ be left exact, and Y a bounded below acyclic complex of G-acyclic objects (Proposition 15.6.6). Then $G(Y)$ is acyclic. Consequently, if Y is any bounded below complex of G-acyclic objects, then $RG(Y) \cong G(Y)$ in $D^+(\mathcal{C})$.*

Proof. Let $Z^n = \ker(Y^n \to Y^{n+1})$. Acyclicity gives short exact sequences $0 \to Z^n \to Y^n \to Z^{n+1} \to 0$, and $Z^n = 0$ for $n \ll 0$. By induction and the long exact sequence of Theorem 15.6.5, all Z^n are G-acyclic, so G preserves the exactness of these sequences ($R^1G(Z^n) = 0$). Since $G(Z^{n+1}) \to G(Y^{n+1})$ is a monomorphism, the kernel of $G(Y^n) \to G(Y^{n+1})$ is $G(Z^n)$, which is the image of $G(Y^{n-1}) \to G(Z^n) \to G(Y^n)$; so $G(Y)$ is acyclic. For the second statement, let $Y \to I$ be a quasi-isomorphism to a complex of injectives; its cone is a bounded below acyclic complex (Proposition 15.4.5) of G-acyclic objects (termwise $Y^{n+1} \oplus I^n$, and R^kG is additive). By the first statement $G(\mathrm{Cone}) = \mathrm{Cone}(G(Y) \to G(I))$ is acyclic, so $G(Y) \to G(I) = RG(Y)$ is a quasi-isomorphism. □

Theorem 17.4.7. *Let $F\colon \mathcal{A} \to \mathcal{B}$ and $G\colon \mathcal{B} \to \mathcal{C}$ be left exact, with $\mathcal{A}$ and $\mathcal{B}$ having enough injectives, and suppose F sends injectives to G-acyclic objects. Then $R(G \circ F) \cong RG \circ RF$.*

Proof. For $X \in D^+(\mathcal{A})$ with resolution $X \to I_X$, $RF(X) = F(I_X)$ is a bounded below complex of G-acyclic objects, so $RG(RF(X)) \cong G(F(I_X)) = R(GF)(X)$ by Lemma 17.4.6. □

Proposition 17.4.8 (Hypercohomology spectral sequences)**.** *Let F be left exact, $\mathcal{A}$ with enough injectives, and X a complex with $X^n = 0$ for $n < 0$. There are convergent first-quadrant spectral sequences*

$$'E_1^{p,q} = R^qF(X^p) \Rightarrow R^{p+q}F(X), \qquad ''E_2^{p,q} = R^pF(H^q(X)) \Rightarrow R^{p+q}F(X).$$

Proof. Let J be a Cartan–Eilenberg resolution of X; by the proof of Proposition 17.4.3, $RF(X) = F(\mathrm{Tot}(J)) = \mathrm{Tot}(F(J))$. Filtering by columns as in the proof of Theorem 16.4.1, $'E_1^{p,q} = H_v^q(F(J^{p,\bullet})) = R^qF(X^p)$, since $J^{p,\bullet}$ is an injective resolution of X^p. Filtering by rows, the rows of J are split (second filtration in the proof of Theorem 16.6.3), so $H_h^q(F(J)) = F(H_h^q(J))$, and $H_h^q(J)^\bullet$ is an injective resolution of $H^q(X)$; hence $''E_2^{p,q} = H^p(F(H_h^q(J))) = R^pF(H^q(X))$. Convergence is Theorem 16.4.1. □

17.5 t-structures

Definition 17.5.1. For a complex X and $n \in \mathbb{Z}$ the *truncations* are

$$\tau_{\le n}X = (\cdots \to X^{n-1} \to Z^n(X) \to 0 \to \cdots), \qquad \tau_{\ge n}X = (\cdots \to 0 \to X^n/B^n(X) \to X^{n+1} \to \cdots).$$

Proposition 17.5.2. *There are natural morphisms $\tau_{\le n}X \to X \to \tau_{\ge n}X$, and $H^k(\tau_{\le n}X) = H^k(X)$ for $k \le n$ and 0 otherwise, while $H^k(\tau_{\ge n}X) = H^k(X)$ for $k \ge n$ and 0 otherwise. There is a distinguished triangle $\tau_{\le n}X \to X \to \tau_{\ge n+1}X \to (\tau_{\le n}X)[1]$ in $D(\mathcal{A})$.*

Proof. The cohomology computations are immediate from the definitions. The morphism $X \to \tau_{\ge n+1}X$ is surjective with kernel the complex $K = (\cdots \to X^{n-1} \to X^n \to B^{n+1}(X) \to 0 \to \cdots)$, and $\tau_{\le n}X \to K$ is a quasi-isomorphism (both have cohomology $H^k(X)$ for $k \le n$ and zero above, $H^{n+1}(K) = 0$ as $X^n \to B^{n+1}$ is onto). Finally, a short exact sequence of complexes $0 \to K \xrightarrow{\iota} X \xrightarrow{\pi} Q \to 0$ gives a distinguished triangle $K \to X \to Q \to K[1]$ in $D(\mathcal{A})$: the map $\mathrm{Cone}(\iota) \to Q$, $(a, b) \mapsto \pi(b)$, is a surjective morphism of complexes whose kernel $K^{n+1} \oplus K^n$ is $\mathrm{Cone}(\mathrm{id}_K)$, which is contractible (proof of Theorem 17.2.4); by the long exact sequence (Theorem 15.4.3) it is a quasi-isomorphism, so the triangle of ι is isomorphic in $D(\mathcal{A})$ to $K \to X \to Q \to K[1]$. Apply this to $K \to X \to \tau_{\ge n+1}X$ and replace K by $\tau_{\le n}X$. □

Remark 17.5.3. The full subcategories $D^{\leq 0}$ and $D^{\geq 0}$ of complexes with cohomology in degrees ≤ 0, respectively ≥ 0, form the *standard t-structure* on $D(\mathcal{A})$: $\mathrm{Hom}(D^{\leq 0}, D^{\geq 1}) = 0$, $D^{\leq 0}[1] \subseteq D^{\leq 0}$, and every object sits in a triangle as in Proposition 17.5.2. Its *heart* $D^{\leq 0} \cap D^{\geq 0}$ is equivalent to $\mathcal{A}$. Abstract t-structures, and in particular the perverse t-structure on derived categories of sheaves, were introduced in [BBD82]; perverse sheaves and M. Saito's mixed Hodge modules are the modern setting for the Hodge theory of singular varieties.

17.6 Filtered complexes and strictness

Definition 17.6.1. A *filtered object* (A, F) is an object with a decreasing filtration F^pA, *finite* if $F^aA = A$ and $F^bA = 0$ for some a, b. A morphism $f\colon (A,F) \to (B,F)$ is *filtered* if $f(F^pA) \subseteq F^pB$, and *strict* if $f(F^pA) = f(A) \cap F^pB$ for all p. A morphism of filtered complexes is a *filtered quasi-isomorphism* if it induces quasi-isomorphisms on all gr^p.

Counterexample 17.6.2. Filtered morphisms need not be strict, and the category of filtered vector spaces is not abelian. Let $A = B = k$ with $F^0A = A$, $F^1A = 0$ and $F^0B = F^1B = B$, $F^2B = 0$. The identity $A \to B$ is filtered and bijective, but not strict ($f(F^1A) = 0 \neq F^1B \cap B = k$), and it is not an isomorphism of filtered objects, because its inverse is not filtered. Its kernel and cokernel (with the induced filtrations) are zero, so it is a monomorphism and an epimorphism; by Lemma 15.2.3 the category is not abelian.

Proposition 17.6.3 (Deligne)**.** *Let K be a complex with a filtration that is finite in each degree. The spectral sequence of Theorem 16.3.4 degenerates at E_1 (that is, $d_r = 0$ for all $r \geq 1$) if and only if every differential $d\colon K^n \to K^{n+1}$ is strict. In this case $H^n(\mathrm{gr}^pK) \cong \mathrm{gr}^pH^n(K)$.*

Proof. We use the notation of Definition 16.3.2; strictness of d means $F^p \cap d(K) = d(F^p)$.

Suppose d is strict. Let $x \in Z_r^p$ with $r \geq 1$. Then $dx \in F^{p+1} \cap d(K) = d(F^{p+1})$, so $dx = dy$ with $y \in F^{p+1}$. Since $dy = dx \in F^{p+r}$, $y \in Z_{r-1}^{p+1}$, so x and the cocycle $x - y$ have the same class in E_r^p. Hence every class in E_r^p is represented by a cocycle of K, and $d_r = 0$.

Suppose all d_r, $r \geq 1$, vanish. Fix a degree n. We show $F^p \cap d(K^{n-1}) \subseteq d(F^pK^{n-1})$ for all p by descending induction on p (for p large, $F^pK^n = 0$). Let $y = dx \in F^p$ with $x \in F^aK^{n-1}$; since the filtration is finite in degree $n-1$, it suffices to treat all a, by descending induction on a. If $a \geq p$ there is nothing to show. If $a < p$, then $x \in Z_{p-a}^a$, and $d_{p-a}[x] = [dx] = 0$ in E_{p-a}^p, so $dx \in B_{p-a}^p + Z_{p-a-1}^{p+1}$: $dx = dx' + z$ with $x' \in F^{a+1}$, $dx' \in F^p$, and $z \in F^{p+1}$ with $z = d(x - x') \in d(K)$. By induction on a (as $x' \in F^{a+1}$), $dx' \in d(F^p)$; by induction on p, $z \in d(F^{p+1}) \subseteq d(F^p)$. So $y \in d(F^p)$. The last statement follows from $E_1 = E_\infty$ and Theorem 16.3.4. □

Remark 17.6.4. Localising the homotopy category of filtered complexes at filtered quasi-isomorphisms gives the *filtered derived category* $DF(\mathcal{A})$. Deligne used it to construct mixed Hodge structures on the cohomology of algebraic varieties [Del71]; the degeneration of the Hodge-to-de Rham spectral sequence of a compact Kähler manifold (Chapter 48) is, by Proposition 17.6.3, the strictness of the de Rham differential with respect to the Hodge filtration.

17.7 Exercises

Exercise 17.7.1. Show that in a triangulated category, if (u, v, w) is a morphism of distinguished triangles and two of u, v, w are isomorphisms, so is the third.

Solution. Let (u, v, w) be a morphism from $X \to Y \to Z \to X[1]$ to $X' \to Y' \to Z' \to X'[1]$ with u, v isomorphisms, and let W be any object. Applying $\mathrm{Hom}(W, -)$ and Proposition 17.2.5 gives two long exact sequences of abelian groups connected by the maps induced by u, v, w, $u[1]$, $v[1]$. The five lemma (Lemma 15.4.2) shows that $w_*\colon \mathrm{Hom}(W, Z) \to \mathrm{Hom}(W, Z')$ is bijective for all W. Taking $W = Z'$ gives $s\colon Z' \to Z$ with $ws = \mathrm{id}$; then $w(sw) = w$, and injectivity of w_* for $W = Z$ gives $sw = \mathrm{id}$. The other cases follow by rotating the triangles with (TR2). □

Exercise 17.7.2. Let k be a field. Show that every complex X of k-vector spaces is isomorphic in $D(\mathsf{Vect}_k)$ to the complex $\bigoplus_n H^n(X)[-n]$ with zero differential.

Solution. Every subspace has a complement. Choose complements $X^n = Z^n \oplus C^n$ and $Z^n = B^n \oplus H^n$, where $H^n \cong H^n(X)$. The subcomplex $H = \bigoplus_n H^n$ has zero differential. Choose linear maps $r^n\colon X^n \to H^n$ that are the identity on H^n and vanish on $B^n \oplus C^n$. Then $r\colon X \to H$ is a morphism of complexes: $r(dx) = 0$ because $dx \in B^{n+1}$. It induces the identity on cohomology, so it is a quasi-isomorphism, hence an isomorphism in $D(\mathsf{Vect}_k)$. □

Exercise 17.7.3. Using Proposition 17.4.5, define the Yoneda product $\mathrm{Ext}^m(Y, Z) \times \mathrm{Ext}^n(X, Y) \to \mathrm{Ext}^{m+n}(X, Z)$ as composition in $D(\mathcal{A})$ and show that it is associative.

Exercise 17.7.4. Show that $D(\mathcal{A})$ is not abelian unless every short exact sequence in $\mathcal{A}$ splits. (Hint: a monomorphism in a triangulated category is split.)

Solution. Let $f\colon X \to Y$ be a monomorphism in a triangulated category, and complete it to a triangle $Z[-1] \xrightarrow{h} X \xrightarrow{f} Y \to Z$. Then $fh = 0$, so $h = 0$. Applying Proposition 17.2.5 with $\mathrm{Hom}(-, X)$ shows that $\mathrm{Hom}(Y, X) \to \mathrm{Hom}(X, X)$ is surjective (the next term maps through $h = 0$), so f has a retraction. Dually, epimorphisms have sections.

Suppose $D(\mathcal{A})$ is abelian and let $0 \to A \to B \xrightarrow{g} C \to 0$ be exact in $\mathcal{A}$. As in the proof of Proposition 17.5.2, it gives a distinguished triangle $A \to B \xrightarrow{g} C \xrightarrow{\delta} A[1]$. Factor $\delta = me$ with $e\colon C \to I$ an epimorphism and $m\colon I \to A[1]$ a monomorphism. Both split, so I is a direct summand of C and of $A[1]$ in $D(\mathcal{A})$. Cohomology is additive, so $H^k(I)$ vanishes for $k \neq 0$ (as a summand of C) and for $k \neq -1$ (as a summand of $A[1]$). Hence I is acyclic, $I \cong 0$ and $\delta = 0$. By Proposition 17.2.5, the sequence $\mathrm{Hom}(C, B) \to \mathrm{Hom}(C, C) \to \mathrm{Hom}(C, A[1])$ is exact and $\mathrm{id}_C \mapsto \delta = 0$, so $g\sigma = \mathrm{id}_C$ for some $\sigma\colon C \to B$ in $D(\mathcal{A})$. Applying H^0 gives $g \circ H^0(\sigma) = \mathrm{id}_C$ in $\mathcal{A}$, so the sequence splits. □

Part III

Topology

Chapter 18

General Topology

18.1 Introduction

Topology axiomatises the notions of nearness and continuity. This chapter develops the point-set topology used in the rest of the project: metric spaces for analysis, quotients and compactness for geometry, and paracompactness and partitions of unity, which are the basic tool for passing from local to global constructions on manifolds. The main theorems are Tychonoff's theorem (Theorem 18.6.8), the characterisation of compact metric spaces (Theorem 18.7.4), the Baire category theorem (Theorem 18.7.8), Urysohn's lemma and the Tietze extension theorem (Theorems 18.8.4 and 18.8.5), and the existence of partitions of unity (Theorem 18.10.6). The last sections treat spaces of continuous maps with the compact-open topology, the exponential law and the Arzelà–Ascoli theorem (Section 18.11), convergence in general spaces by nets and ultrafilters (Section 18.12), the Stone–Čech compactification (Section 18.13), and the Cantor set and space-filling curves (Section 18.14). Standard references are [Mun00] and [Eng89].

Prerequisites. Chapter 3 (Set Theory), Chapter 4 (Number Systems), Chapter 6 (Categories) and Chapter 11 (Linear Algebra).

On the way to the Hodge conjecture. Needed: Sections 18.2 to 18.7, the separation axioms up to Urysohn's lemma and the Tietze extension theorem, local compactness, and paracompactness with partitions of unity. The hierarchy of separation axioms and separability (the last two subsections of Section 18.8), function spaces, nets and filters, the Stone–Čech compactification and the Cantor set (Sections 18.11, 18.12, 18.13 and 18.14) are not used on the direct route.

18.2 Topological spaces and continuous maps

Why open sets. In analysis, "x_n tends to x" and "f is continuous at x" are expressed with distances: $|x_n - x| < \varepsilon$ eventually, $|f(y) - f(x)| < \varepsilon$ when $|y - x| < \delta$. Looking closely, the actual numbers ε and δ do not matter, only the sets $\{y : |y - x| < \delta\}$ and, more precisely, the sets that contain such a ball around each of their points, the *open* sets. For instance $f : \mathbb{R} \to \mathbb{R}$ is continuous if and only if the preimage of every open set is open (Proposition 18.3.5 below). Open sets have three basic properties, all following from the definition: $\emptyset$ and the whole space are open; a union of open sets is open (a ball around a point of the union lies in one of the sets); and the intersection of *two* open sets is open (around a point of the intersection take the smaller of two balls). An infinite intersection need not be open: the intervals $(-\frac{1}{n}, \frac{1}{n})$ are open and their intersection is $\{0\}$, which contains no ball. A topology is a choice of "open sets" with exactly these three properties, and nothing else; this is enough to speak of limits

and continuity, and it applies to spaces where no natural distance exists, such as quotient spaces, spaces of functions with pointwise convergence, or the Zariski topology of algebraic geometry.

Definition 18.2.1. A *topology* on a set X is a set $\mathcal{T}$ of subsets of X, called *open* sets, such that $\emptyset$ and X are open, every union of open sets is open, and every finite intersection of open sets is open. A *topological space* is a set with a topology. A subset $C \subseteq X$ is *closed* if $X \setminus C$ is open. A *neighbourhood* of a point x (or of a subset A) is a set containing an open set containing x (or A). If $\mathcal{T} \subseteq \mathcal{T}'$ are two topologies on X, then $\mathcal{T}'$ is *finer* and $\mathcal{T}$ is *coarser*.

Example 18.2.2.

1. The *discrete* topology $\mathcal{P}(X)$ and the *indiscrete* topology $\{\emptyset, X\}$ are the finest and the coarsest topologies on X.

2. The *cofinite* topology on X consists of $\emptyset$ and the complements of finite sets. The *cocountable* topology consists of $\emptyset$ and the complements of countable sets.

3. The *Sierpiński space* is $\{0,1\}$ with open sets $\emptyset$, $\{1\}$ and $\{0,1\}$.

4. On a two-point set $\{a,b\}$ there are exactly four topologies: the indiscrete one, the discrete one, and the two Sierpiński topologies $\{\emptyset, \{a\}, \{a,b\}\}$ and $\{\emptyset, \{b\}, \{a,b\}\}$. Indeed a topology must contain $\emptyset$ and $\{a,b\}$, and any choice of which singletons to add satisfies the axioms. The family $\{\emptyset, \{a\}, \{b\}\}$ is not a topology, since the union $\{a\} \cup \{b\}$ and the whole space are missing.

5. The *metric topology* of $\mathbb{R}$ (Section 18.3): U is open if every $x \in U$ has an $\varepsilon > 0$ with $(x-\varepsilon, x+\varepsilon) \subseteq U$. Open intervals and their unions are open; $[0,1)$ is not open (no interval around 0 fits inside) and not closed (its complement $(-\infty, 0) \cup [1, \infty)$ is not open at 1). So "not open" does not mean "closed": a set can be both ($\emptyset$, $\mathbb{R}$), one of the two, or neither.

A finer topology has more open sets. The finer the topology on X, the easier it is for maps *from* X to be continuous and the harder for maps *to* X; every map from a discrete space and every map to an indiscrete space is continuous (Definition 18.2.12 below).

Definition 18.2.3. Let A be a subset of a space X. Its *interior* $\operatorname{int} A$ is the union of all open sets contained in A, its *closure* $\overline{A}$ is the intersection of all closed sets containing A, and its *boundary* is $\partial A = \overline{A} \setminus \operatorname{int} A$. The set A is *dense* if $\overline{A} = X$.

Lemma 18.2.4. *Let $A, B \subseteq X$. Then $\operatorname{int} A$ is the largest open subset of A and $\overline{A}$ is the smallest closed set containing A; $X \setminus \overline{A} = \operatorname{int}(X \setminus A)$; a point x lies in $\overline{A}$ if and only if every open set containing x meets A; and $\overline{A \cup B} = \overline{A} \cup \overline{B}$.*

Proof. The first two statements hold because unions of open sets are open and intersections of closed sets are closed. Taking complements turns closed sets containing A into open sets contained in $X \setminus A$, which gives the third statement. So $x \notin \overline{A}$ if and only if x lies in an open set contained in $X \setminus A$, that is, an open set not meeting A. Finally $\overline{A} \cup \overline{B}$ is closed and contains $A \cup B$, so it contains $\overline{A \cup B}$; the reverse inclusion holds as $\overline{A}, \overline{B} \subseteq \overline{A \cup B}$. □

Definition 18.2.5. Let $A \subseteq X$ and $x \in X$. Then x is an *adherent point* of A if every neighbourhood of x meets A (that is, $x \in \overline{A}$), an *accumulation point* of A if every neighbourhood of x meets $A \setminus \{x\}$, and an *isolated point* of A if $x \in A$ and some neighbourhood of x meets A only in x. The set A' of accumulation points is the *derived set*. A set without isolated points is *dense in itself*, and a closed set without isolated points is *perfect*.

The term *limit point* is used by some authors for accumulation points and by others for adherent points (limits of nets or, in metric spaces, of sequences in A); we avoid it.

Proposition 18.2.6. *Let $A \subseteq X$.*

1. *$\overline{A} = A \cup A'$, and every point of $\overline{A}$ is an accumulation point of A or an isolated point of A, but not both.*
2. *A is closed if and only if $A' \subseteq A$; A is open if and only if it is a neighbourhood of each of its points.*
3. *$\partial A = \overline{A} \cap \overline{X \setminus A}$ is closed; A is closed if and only if $\partial A \subseteq A$, and open if and only if $\partial A \cap A = \emptyset$; $\overline{A} = A \cup \partial A$ and $\operatorname{int} A = A \setminus \partial A$.*
4. *A is dense if and only if it meets every nonempty open set, if and only if $\operatorname{int}(X \setminus A) = \emptyset$.*
5. *If X is Hausdorff, $x \in A'$ if and only if every neighbourhood of x contains infinitely many points of A; in particular finite sets have no accumulation points.*
6. *A point $x \in X$ is isolated in X if and only if $\{x\}$ is open; a dense set contains all isolated points of X.*

Proof. (1) A point of $\overline{A}$ not in A has neighbourhoods meeting $A = A \setminus \{x\}$; a point of A either has a neighbourhood meeting A only in x (isolated) or not (accumulation point), and the two cases exclude each other. Conversely $A' \subseteq \overline{A}$ by Lemma 18.2.4. (2) The first statement follows from (1). If A is open it is a neighbourhood of its points; if A contains an open $U_x \ni x$ for every $x \in A$, then $A = \bigcup_x U_x$ is open. (3) $\overline{X \setminus A} = X \setminus \operatorname{int} A$ by Lemma 18.2.4, so $\overline{A} \cap \overline{X \setminus A} = \overline{A} \setminus \operatorname{int} A$; it is an intersection of closed sets. The other statements follow from $\operatorname{int} A \subseteq A \subseteq \overline{A}$. (4) By Lemma 18.2.4, $\overline{A} = X$ if and only if every point lies in no open set missing A, if and only if no nonempty open set misses A; and $X \setminus \overline{A} = \operatorname{int}(X \setminus A)$. (5) If a neighbourhood U of x meets $A \setminus \{x\}$ only in finitely many points $a_1, \dots, a_k$, choose by the Hausdorff property open sets $U_i \ni x$ not containing a_i; then $U \cap U_1 \cap \cdots \cap U_k$ is a neighbourhood of x missing $A \setminus \{x\}$. (6) The first statement is the definition, and an open $\{x\}$ must meet a dense set by (4). □

Example 18.2.7. In $\mathbb{R}$: for $A = \{1/n : n \geq 1\}$, every point of A is isolated, $A' = \{0\}$, and $\overline{A} = A \cup \{0\}$; so A is neither open nor closed. $\mathbb{Z}$ has no accumulation points and is closed. $\mathbb{Q}$ is dense, with $\mathbb{Q}' = \mathbb{R}$, and has empty interior, so $\partial\mathbb{Q} = \mathbb{R}$. A closed interval $[a, b]$ $(a < b)$ is perfect. In the indiscrete topology on a set with at least two points, every point is an accumulation point of every nonempty set other than a singleton, and (5) fails: the space is not Hausdorff.

Example 18.2.8. In $\mathbb{R}$ with its usual topology:

1. For $A = [0, 1)$: $\operatorname{int} A = (0, 1)$, $\overline{A} = [0, 1]$ and $\partial A = \{0, 1\}$. For $A = (0, 1) \cup \{2\}$: $\operatorname{int} A = (0, 1)$, $\overline{A} = [0, 1] \cup \{2\}$, and $\partial A = \{0, 1, 2\}$; the isolated point 2 belongs to the boundary although it belongs to A.
2. For $A = \mathbb{Q}$: $\operatorname{int} \mathbb{Q} = \emptyset$ (every interval contains irrationals), $\overline{\mathbb{Q}} = \mathbb{R}$ (every interval contains rationals), and $\partial\mathbb{Q} = \mathbb{R}$.
3. The closure does not commute with intersections: for $A = (0, 1)$ and $B = (1, 2)$, $\overline{A \cap B} = \emptyset$ while $\overline{A} \cap \overline{B} = \{1\}$; in general only $\overline{A \cap B} \subseteq \overline{A} \cap \overline{B}$ holds. It commutes with finite unions (Lemma 18.2.4) but not with infinite ones: the sets $\{\frac{1}{n}\}$ are closed, while their union has closure $\{\frac{1}{n}\} \cup \{0\}$.

In the discrete topology every set is open and closed, so $\operatorname{int} A = A = \overline{A}$ and $\partial A = \emptyset$. In the indiscrete topology on X, a nonempty $A \neq X$ has $\operatorname{int} A = \emptyset$ and $\overline{A} = X$: the topology is too coarse to distinguish the points of A from the others.

Definition 18.2.9. A *basis* of a topology $\mathcal{T}$ is a subset $\mathcal{B} \subseteq \mathcal{T}$ such that every open set is a union of members of $\mathcal{B}$. A *subbasis* is a subset $\mathcal{S} \subseteq \mathcal{T}$ such that the finite intersections of members of $\mathcal{S}$ (the empty intersection being X) form a basis.

Lemma 18.2.10. *1. A set $\mathcal{B}$ of subsets of X is a basis of some topology if and only if $\mathcal{B}$ covers X and for all $B_1, B_2 \in \mathcal{B}$ and $x \in B_1 \cap B_2$ there is $B_3 \in \mathcal{B}$ with $x \in B_3 \subseteq B_1 \cap B_2$. This topology consists of the unions of members of $\mathcal{B}$.*

2. For every set $\mathcal{S}$ of subsets of X there is a coarsest topology containing $\mathcal{S}$, the topology generated *by $\mathcal{S}$, and $\mathcal{S}$ is a subbasis of it.*

Proof. (1) If $\mathcal{B}$ is a basis, then X is a union of members and $B_1 \cap B_2$ is open, hence a union of members, which gives the two conditions. Conversely, let $\mathcal{T}$ be the set of unions of members of $\mathcal{B}$. It contains $\emptyset$ (the empty union) and X (first condition), and is closed under unions. If $U = \bigcup_i B_i$ and $V = \bigcup_j B'_j$, then $U \cap V = \bigcup_{i,j} B_i \cap B'_j$, and each $B_i \cap B'_j$ is a union of members of $\mathcal{B}$ by the second condition. By induction $\mathcal{T}$ is closed under finite intersections.

(2) The set $\mathcal{B}$ of finite intersections of members of $\mathcal{S}$ contains X and is closed under finite intersections, so it satisfies the conditions of (1). The topology it generates contains $\mathcal{S}$, and every topology containing $\mathcal{S}$ contains $\mathcal{B}$ and all unions of its members. □

Example 18.2.11. 1. In a metric space the open balls form a basis (Section 18.3). In $\mathbb{R}$ already the intervals (p, q) with rational endpoints form a basis: if $x \in U$ open, there is $(x - \varepsilon, x + \varepsilon) \subseteq U$, and rationals $p \in (x - \varepsilon, x)$, $q \in (x, x + \varepsilon)$ give $x \in (p, q) \subseteq U$. This basis is countable, so $\mathbb{R}$ is second countable.

2. The rays $(-\infty, a)$ and (b, ∞) form a subbasis of the topology of $\mathbb{R}$ which is not a basis: the interval $(0, 1) = (-\infty, 1) \cap (0, \infty)$ is open but not a union of rays.

3. The half-open intervals $[a, b)$ satisfy the conditions of Lemma 18.2.10(1), so they are a basis of a topology, the *Sorgenfrey line*; it is finer than the usual topology, since $(a, b) = \bigcup_n [a + \frac{1}{n}, b)$, and strictly finer, since $[0, 1)$ is open in it.

Definition 18.2.12. A map $f : X \to Y$ between spaces is *continuous* if $f^{-1}(V)$ is open for every open $V \subseteq Y$. It is a *homeomorphism* if it is bijective and both f and f^{-1} are continuous. It is *open* (*closed*) if it maps open (closed) sets to open (closed) sets.

Proposition 18.2.13. *For a map $f : X \to Y$ the following are equivalent:*

1. *f is continuous;*
2. *$f^{-1}(C)$ is closed for every closed $C \subseteq Y$;*
3. *$f(\overline{A}) \subseteq \overline{f(A)}$ for every $A \subseteq X$;*
4. *for every $x \in X$ and every open $V \ni f(x)$ there is an open $U \ni x$ with $f(U) \subseteq V$;*
5. *$f^{-1}(S)$ is open for every member S of a subbasis of Y.*

Compositions of continuous maps are continuous, so spaces and continuous maps form a category Top.

Proof. (1)⇔(2) since $f^{-1}(Y \setminus C) = X \setminus f^{-1}(C)$. (2)⇒(3): $f^{-1}(\overline{f(A)})$ is closed and contains A, hence contains $\overline{A}$. (3)⇒(2): if C is closed and $A = f^{-1}(C)$, then $f(\overline{A}) \subseteq \overline{f(A)} \subseteq C$, so $\overline{A} \subseteq A$. (1)⇒(4): take $U = f^{-1}(V)$. (4)⇒(1): $f^{-1}(V)$ is the union of the open sets U provided by (4) for its points. (1)⇔(5): preimages commute with unions and intersections, and every open set is a union of finite intersections of members of the subbasis. The last statement follows from $(g \circ f)^{-1}(W) = f^{-1}(g^{-1}(W))$. □

Example 18.2.14. 1. Constant maps are continuous: the preimage of any set is $\emptyset$ or the whole space. The identity of X is continuous from a finer to a coarser topology, and only in that direction.

2. The floor function $\lfloor\cdot\rfloor\colon \mathbb{R} \to \mathbb{R}$ is not continuous: the preimage of the open interval $(-\frac{1}{2}, \frac{1}{2})$ is $[0, 1)$, which is not open. In terms of (4), at $x = 0$ the open set $V = (-\frac{1}{2}, \frac{1}{2}) \ni 0 = \lfloor 0 \rfloor$ contains $\lfloor U \rfloor$ for no open $U \ni 0$, since U contains negative numbers. It is continuous at every non-integer, where it is locally constant.

3. The indicator function $\mathbf{1}_{\mathbb{Q}}$ is continuous at no point, since every interval contains rational and irrational points; restricted to the subspace $\mathbb{Q}$ it is constant, hence continuous. Continuity depends on the topologies on both sides, and restricting a map to a subspace can make it continuous.

Counterexample 18.2.15. A continuous bijection need not be a homeomorphism: the identity map from X with the discrete topology to X with the indiscrete topology is continuous, and its inverse is not if X has at least two points.

Proposition 18.2.16. *For a bijection $f\colon X \to Y$ the following are equivalent:*

1. *f is a homeomorphism;*
2. *f is continuous and open;*
3. *f is continuous and closed;*
4. *$f(\overline{A}) = \overline{f(A)}$ for every $A \subseteq X$;*
5. *$U \subseteq X$ is open if and only if $f(U)$ is open.*

Proof. For a bijection, $(f^{-1})^{-1}(U) = f(U)$, so f^{-1} is continuous if and only if f is open, if and only if (taking complements) f is closed; this gives (1)⇔(2)⇔(3), and (5) is (2) written out. (1)⇒(4): by Proposition 18.2.13(3) applied to f and to f^{-1}, $f(\overline{A}) \subseteq \overline{f(A)}$ and $f^{-1}(\overline{f(A)}) \subseteq \overline{A}$. (4)⇒(3): f is continuous by Proposition 18.2.13(3), and if C is closed, $f(C) = f(\overline{C}) = \overline{f(C)}$ is closed. □

So a homeomorphism is a bijection of the points that is also a bijection of the open sets: every topological property (being open, closed, dense, compact, connected, Hausdorff, ...) is preserved. Two further criteria are proved later: a continuous bijection from a compact space to a Hausdorff space is a homeomorphism (Proposition 18.6.3(4)), and by Brouwer's *invariance of domain* a continuous injection from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^n$ is open, hence a homeomorphism onto an open image [Hat02, Theorem 2B.3]. Examples: $x \mapsto x/(1 - |x|)$ is a homeomorphism from the open ball $B(0, 1) \subseteq \mathbb{R}^n$ onto $\mathbb{R}^n$, with inverse $y \mapsto y/(1 + |y|)$, so all open balls are homeomorphic to $\mathbb{R}^n$; $t \mapsto e^{2\pi i t}$ is a continuous bijection $[0, 1) \to S^1$ that is not a homeomorphism, since S^1 is compact and $[0, 1)$ is not; and $\mathbb{R}$ is not homeomorphic to $\mathbb{R}^2$, since removing a point disconnects $\mathbb{R}$ but not $\mathbb{R}^2$ (Section 18.5).

Definition 18.2.17. A space X is *Hausdorff* if any two distinct points have disjoint open neighbourhoods. A sequence $(x_n)_{n\in\mathbb{N}}$ in X *converges* to x if every open set containing x contains x_n for all sufficiently large n.

Lemma 18.2.18. *In a Hausdorff space every sequence has at most one limit, and every finite subset is closed.*

Proof. If $x \neq y$ are limits, take disjoint open $U \ni x$ and $V \ni y$; for large n, $x_n \in U \cap V$, a contradiction. For a point x, every $y \neq x$ has an open neighbourhood not containing x, so $X \setminus \{x\}$ is open; finite unions of closed sets are closed. □

Counterexample 18.2.19. The cofinite topology on an infinite set X is not Hausdorff: two nonempty open sets have finite complements, and the union of these complements is not all of X, so they meet. In this space every injective sequence converges to every point, since an open set misses only finitely many of its terms.

18.3 Metric spaces

Definition 18.3.1. A *metric* on a set X is a map $d\colon X \times X \to \mathbb{R}$ such that for all $x, y, z \in X$: $d(x,y) \geq 0$ with equality if and only if $x = y$; $d(x,y) = d(y,x)$; and $d(x,z) \leq d(x,y) + d(y,z)$ (the *triangle inequality*). The *open ball* of radius $r > 0$ around x is $B(x,r) = \{y : d(x,y) < r\}$. A set A is *bounded* if $A \subseteq B(x,r)$ for some x and r.

Lemma 18.3.2. *The open balls of a metric space form a basis of a topology, the* metric topology*: U is open if and only if for every $x \in U$ there is $\varepsilon > 0$ with $B(x,\varepsilon) \subseteq U$. It is Hausdorff. A space whose topology is the metric topology of some metric is* metrisable*.*

Proof. If $x \in B(a,r) \cap B(b,s)$, let $\varepsilon = \min(r - d(a,x), s - d(b,x)) > 0$. By the triangle inequality $B(x,\varepsilon)$ is contained in both balls, so Lemma 18.2.10 applies; the description of open sets follows. If $x \neq y$ and $r = d(x,y)$, the balls $B(x,r/2)$ and $B(y,r/2)$ are disjoint by the triangle inequality. □

Definition 18.3.3. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$, with absolute value $|\cdot|$. A *norm* on a $\mathbb{K}$-vector space V is a map $\|\cdot\|\colon V \to \mathbb{R}$ such that $\|v\| = 0$ only for $v = 0$, $\|\lambda v\| = |\lambda|\,\|v\|$ and $\|v + w\| \leq \|v\| + \|w\|$ (so $\|v\| \geq 0$). Then $d(v,w) = \|v - w\|$ is a metric. On $\mathbb{K}^n$ we use the *Euclidean norm* $\|x\|_2 = (\sum_i |x_i|^2)^{1/2}$, the norm of the standard inner product (a norm by Proposition 11.10.2), and the *maximum norm* $\|x\|_\infty = \max_i |x_i|$.

Lemma 18.3.4. *If d, d' are metrics on X with $c\,d \leq d' \leq C\,d$ for constants $c, C > 0$, they define the same topology. In particular, since $\|x\|_\infty \leq \|x\|_2 \leq \sqrt{n}\,\|x\|_\infty$, the two norms on $\mathbb{K}^n$ define the same topology. On $\mathbb{R}$ it is the topology with basis the open intervals, the* standard topology*.*

Proof. $B_{d'}(x, c\varepsilon) \subseteq B_d(x,\varepsilon)$ and $B_d(x, \varepsilon/C) \subseteq B_{d'}(x,\varepsilon)$, so the criterion of Lemma 18.3.2 gives the same open sets. The norm inequalities hold because $\max_i |x_i|^2 \leq \sum_i |x_i|^2 \leq n \max_i |x_i|^2$. On $\mathbb{R}$ the balls are the bounded open intervals $(a - r, a + r)$, and every bounded open interval is such a ball. □

Proposition 18.3.5. *Let $f\colon X \to Y$ be a map of metric spaces.*

1. *f is continuous if and only if for every x and $\varepsilon > 0$ there is $\delta > 0$ with $d(f(x), f(x')) < \varepsilon$ whenever $d(x,x') < \delta$.*
2. *For $A \subseteq X$, a point x lies in $\overline{A}$ if and only if it is the limit of a sequence in A.*

3. *f is continuous if and only if $f(x_n) \to f(x)$ whenever $x_n \to x$.*

Proof. (1) is Proposition 18.2.13(4) with balls. (2) If $x \in \overline{A}$, choose $a_n \in A \cap B(x, 1/(n+1))$ by Lemma 18.2.4; then $a_n \to x$. Conversely, if $a_n \to x$, every open set containing x contains some a_n. (3) If f is continuous and $x_n \to x$, every open $V \ni f(x)$ has open preimage containing x, hence containing x_n for large n. If f is not continuous at x, there are $\varepsilon > 0$ and x_n with $d(x, x_n) < 1/(n+1)$ and $d(f(x), f(x_n)) \geq \varepsilon$; then $x_n \to x$ but $f(x_n) \not\to f(x)$. □

Remark 18.3.6. *Limits of maps.* Let $f : X \to Y$ be a map of topological spaces and $x_0 \in X$ a point that is not isolated, that is, every neighbourhood of x_0 contains points other than x_0. One writes $\lim_{x \to x_0} f(x) = y$ if for every neighbourhood V of y there is a neighbourhood U of x_0 with $f(U \setminus \{x_0\}) \subseteq V$; the value $f(x_0)$ plays no role. If Y is Hausdorff the limit is unique: limits $y \neq y'$ with disjoint neighbourhoods V, V' would give neighbourhoods U, U' with $f(U \cap U' \setminus \{x_0\}) \subseteq V \cap V' = \emptyset$, although $U \cap U'$ contains points other than x_0. By Proposition 18.2.13(4), applied at the single point x_0, f is *continuous at* x_0 exactly when

$$\lim_{x \to x_0} f(x) = f(x_0),$$

the condition at x_0 itself being automatic; and f is continuous if and only if it is continuous at every point. At an isolated point every map is continuous, and the limit is not defined (every y would satisfy the condition). For metric spaces, $\lim_{x \to x_0} f(x) = y$ means that for every $\varepsilon > 0$ there is $\delta > 0$ with $d(f(x), y) < \varepsilon$ whenever $0 < d(x, x_0) < \delta$, and, as in the proof of (3) above, it is equivalent to $f(x_n) \to y$ for every sequence $x_n \to x_0$ with $x_n \neq x_0$. For $X \subseteq \mathbb{R}$ this is the limit of real analysis (Chapter 27).

Example 18.3.7. *The closed ball and the closure of the ball.* In a metric space the closed ball $\bar{B}(x, r) = \{y : d(x, y) \leq r\}$ is closed (its complement is open by the triangle inequality), so it contains the closure $\overline{B(x, r)}$ of the open ball. They can differ: for the discrete metric ($d(x, y) = 1$ for $x \neq y$) on a set with at least two points, $B(x, 1) = \{x\}$ is closed, while $\bar{B}(x, 1)$ is the whole space. In a normed space, for $r > 0$ they agree: if $\|y - x\| = r$, the points $x + t(y - x)$, $0 < t < 1$, lie in $B(x, r)$ and tend to y. Similarly the boundary of $B(x, r)$ is contained in the sphere $\{d(x, y) = r\}$, with equality in normed spaces but not in general.

Counterexample 18.3.8. In general spaces sequences do not detect closures. Give $\mathbb{R}$ the cocountable topology. If $x_n \to x$, the set $C = \{x_n : x_n \neq x\}$ is countable, so $\mathbb{R} \setminus C$ is an open set containing x, and hence $x_n = x$ for large n. Now $A = \mathbb{R} \setminus \{0\}$ is uncountable (Proposition 4.8.6), so the only closed set containing it is $\mathbb{R}$ and $0 \in \overline{A}$; but no sequence in A converges to 0. Nets or filters replace sequences in general (Section 18.12).

Proposition 18.3.9. *Addition and multiplication $\mathbb{K} \times \mathbb{K} \to \mathbb{K}$ are continuous for the metric $\|(x, y) - (a, b)\|_\infty$, and so is $x \mapsto 1/x$ on $\mathbb{K} \setminus \{0\}$.*

Proof. We have $|(x + y) - (a + b)| \leq |x - a| + |y - b|$, and if $|x - a|, |y - b| < \delta \leq 1$ then $|xy - ab| \leq |x||y - b| + |b||x - a| \leq (|a| + 1 + |b|)\delta$. If $|x - a| < |a|/2$ then $|x| > |a|/2$ and $|1/x - 1/a| = |x - a|/(|x||a|) \leq 2|x - a|/|a|^2$. In each case the criterion of Proposition 18.3.5(1) holds. □

Proposition 18.3.10. *Let X be a space, (Y, d) a metric space and $f_n : X \to Y$ continuous maps converging* uniformly *to f: for every $\varepsilon > 0$ there is N with $d(f_n(x), f(x)) < \varepsilon$ for all $n \geq N$ and all x. Then f is continuous.*

Proof. Let $x \in X$ and $\varepsilon > 0$. Choose n with $d(f_n, f) < \varepsilon/3$ everywhere, and an open $U \ni x$ with $d(f_n(x), f_n(x')) < \varepsilon/3$ for $x' \in U$. Then $d(f(x), f(x')) < \varepsilon$ for $x' \in U$, and Proposition 18.2.13(4) applies. □

Definition 18.3.11. A space is *first countable* if every point x has countably many open neighbourhoods such that every open set containing x contains one of them; *second countable* if its topology has a countable basis; *separable* if it has a countable dense subset; and *Lindelöf* if every open cover has a countable subcover.

Proposition 18.3.12. *Metric spaces are first countable. Second countable spaces are separable and Lindelöf. A separable metric space is second countable. In particular $\mathbb{R}^n$ and $\mathbb{C}^n$ are second countable.*

Proof. The balls $B(x, 1/(n+1))$ show first countability. Let $\mathcal{B}$ be a countable basis. Choosing a point in each nonempty member gives a countable set meeting every nonempty open set, hence dense by Lemma 18.2.4. Given an open cover $\mathcal{U}$, for each $B \in \mathcal{B}$ contained in some member of $\mathcal{U}$ choose one such member U_B; these countably many sets cover, because a point $x \in U \in \mathcal{U}$ lies in some $B \in \mathcal{B}$ with $B \subseteq U$, and then $x \in U_B$. If D is a countable dense subset of a metric space, the balls $B(q, 1/n)$ with $q \in D$, $n \geq 1$ form a basis: if $x \in U$ with U open, choose n with $B(x, 2/n) \subseteq U$ and $q \in D \cap B(x, 1/n)$; then $x \in B(q, 1/n) \subseteq B(x, 2/n) \subseteq U$. Finally $\mathbb{Q}^n$ and $(\mathbb{Q} + i\mathbb{Q})^n$ are countable (Corollary 3.6.13) and dense, by density of $\mathbb{Q}$ in $\mathbb{R}$ (Proposition 4.7.3). □

Counterexample 18.3.13 (The Sorgenfrey line)**.** The half-open intervals $[a, b)$ form a basis of a topology on $\mathbb{R}$, the *Sorgenfrey line*, finer than the Euclidean topology. It is first countable (the sets $[x, x + 1/n)$ form a neighbourhood basis at x) and separable ($\mathbb{Q}$ is dense, as every $[a, b)$ contains a rational number). It is not second countable: if $\mathcal{B}$ is a basis, then for each x some $B_x \in \mathcal{B}$ satisfies $x \in B_x \subseteq [x, x + 1)$, so $x = \min B_x$, and $x \mapsto B_x$ is injective from the uncountable set $\mathbb{R}$ to $\mathcal{B}$. By Proposition 18.3.12, it is therefore not metrisable: separable metric spaces are second countable.

18.4 Subspaces, products and quotients

Definition 18.4.1. Let X be a set. For a family of maps $f_i \colon X \to X_i$ into spaces, the *initial topology* is the topology generated by the sets $f_i^{-1}(U)$, $U \subseteq X_i$ open. For a family of maps $g_i \colon X_i \to X$ from spaces, the *final topology* consists of the sets $U \subseteq X$ such that $g_i^{-1}(U)$ is open for all i.

Proposition 18.4.2. *With the initial topology, a map $h \colon Z \to X$ from a space is continuous if and only if every $f_i \circ h$ is continuous. With the final topology, a map $h \colon X \to Z$ to a space is continuous if and only if every $h \circ g_i$ is continuous.*

Proof. The final topology is a topology because preimages commute with unions and intersections. For the initial topology, $h^{-1}(f_i^{-1}(U)) = (f_i h)^{-1}(U)$ and Proposition 18.2.13(5) give the claim. For the final topology, $h^{-1}(W)$ is open if and only if $g_i^{-1}(h^{-1}(W)) = (hg_i)^{-1}(W)$ is open for all i. □

Definition 18.4.3. The *subspace topology* on $A \subseteq X$ is the initial topology for the inclusion: its open sets are the sets $U \cap A$ with U open in X, and its closed sets are the sets $C \cap A$ with C closed in X. An *embedding* is a map $f \colon X \to Y$ that is a homeomorphism onto $f(X)$ with the subspace topology.

Example 18.4.4. 1. In $A = [0, 1] \subseteq \mathbb{R}$ the set $[0, \frac{1}{2}) = (-1, \frac{1}{2}) \cap A$ is open, although it is not open in $\mathbb{R}$: "open" is relative to the ambient space. Similarly $[0, 1]$ is open and closed in itself. If A is open in X, the open subsets of A are exactly the open subsets of X contained in A; if A is closed, the same holds for closed subsets.

2. $\mathbb{Z} \subseteq \mathbb{R}$ has the discrete topology: $\{n\} = (n - \frac{1}{2}, n + \frac{1}{2}) \cap \mathbb{Z}$ is open. The subspace $\{0\} \cup \{\frac{1}{n} : n \geq 1\}$ is not discrete, as every open set containing 0 contains some $\frac{1}{n}$; and $\mathbb{Q}$ is not discrete either. So two subspaces can be in bijection without being homeomorphic: $\mathbb{Z}$ and $\{0\} \cup \{\frac{1}{n}\}$ are both countable.

3. The inclusion $A \to X$ of a subspace is continuous, and a map $Z \to A$ is continuous if and only if its composite with the inclusion is (Proposition 18.4.2).

Lemma 18.4.5 (Pasting lemma)**.** *Let $f : X \to Y$ be a map and suppose $X = \bigcup_i A_i$, where either all A_i are open, or there are finitely many A_i and all are closed. If every restriction $f|_{A_i}$ is continuous, then f is continuous.*

Proof. For $V \subseteq Y$ we have $f^{-1}(V) = \bigcup_i (f|_{A_i})^{-1}(V)$. In the first case, for V open each $(f|_{A_i})^{-1}(V)$ is open in the open set A_i, hence open in X. In the second case, for V closed each term is closed in the closed set A_i, hence closed in X, and a finite union of closed sets is closed. □

Definition 18.4.6. The *product* of a family of spaces $(X_i)_{i \in I}$ is the set $\prod_i X_i$ with the initial topology for the projections $p_i \colon \prod_j X_j \to X_i$, the *product topology*. The *disjoint union* $\coprod_i X_i$ carries the final topology for the inclusions.

Proposition 18.4.7. *1. The sets $\prod_i U_i$, with $U_i \subseteq X_i$ open and $U_i = X_i$ for all but finitely many i, form a basis of the product topology.*

2. $\prod_i X_i$ with the projections is a product in Top*, and $\coprod_i X_i$ with the inclusions is a coproduct, in the sense of Example 6.8.3.*

3. The projections are open maps. A product of Hausdorff spaces is Hausdorff, and so is a subspace of a Hausdorff space.

4. The product topology on $\mathbb{K}^n = \mathbb{K} \times \cdots \times \mathbb{K}$ is the topology of the Euclidean norm.

5. For every space X, sums and products of continuous functions $X \to \mathbb{K}$ are continuous, and so is $1/g$ for continuous $g \colon X \to \mathbb{K} \setminus \{0\}$.

Proof. (1) These sets are the finite intersections of the subbasic sets $p_i^{-1}(U_i)$. (2) By Proposition 18.4.2, a map $h \colon Z \to \prod_i X_i$ is continuous if and only if all its components $p_i h$ are; so continuous families $Z \to X_i$ correspond bijectively to continuous maps $Z \to \prod_i X_i$. Dually for disjoint unions. (3) The image of a basic open set under p_i is U_i, and images commute with unions. If $x \neq y$ in the product, then $x_i \neq y_i$ for some i, and preimages under p_i of disjoint neighbourhoods of x_i, y_i separate x, y. For subspaces intersect with A. (4) By Lemma 18.3.4 we may use $\| \cdot \|_\infty$, whose balls are products of balls; and every basic open set $\prod_i U_i$ contains, around each of its points a, the $\| \cdot \|_\infty$-ball of radius $\min_i \varepsilon_i$, where $B(a_i, \varepsilon_i) \subseteq U_i$. (5) If f, g are continuous, then $(f, g) \colon X \to \mathbb{K}^2$ is continuous by (2), and $\mathbb{K}^2$ carries the metric topology of $\| \cdot \|_\infty$ by (4); compose with the maps of Proposition 18.3.9. □

Counterexample 18.4.8. The *box topology* on $\prod_i X_i$, with basis all products of open sets, is finer than the product topology and does not have the universal property of the product. The map $\mathbb{R} \to \mathbb{R}^{\mathbb{N}}$, $t \mapsto (t, t, \ldots)$, has continuous components, but the preimage of the box $\prod_n (-1/(n+1), 1/(n+1))$ is $\{0\}$, which is not open.

Definition 18.4.9. A surjective map $q \colon X \to Y$ from a space is a *quotient map* if Y carries the final topology: $V \subseteq Y$ is open if and only if $q^{-1}(V)$ is open. For an equivalence relation $\sim$ on X, the *quotient space* $X/\!\sim$ is the set of classes with the final topology for the projection. For $A \subseteq X$, X/A denotes the quotient identifying all points of A with each other.

Proposition 18.4.10. *Let $q\colon X \to Y$ be a quotient map. A map $h\colon Y \to Z$ is continuous if and only if $h \circ q$ is continuous; hence every continuous map $g\colon X \to Z$ that is constant on the fibres of q factors uniquely as $g = \bar{g} \circ q$ with $\bar{g}$ continuous. A continuous surjection that is open or closed is a quotient map.*

Proof. The first statement is Proposition 18.4.2; $\bar{g}$ is well defined as a map of sets because g is constant on fibres. If $f\colon X \to Y$ is a continuous open surjection and $f^{-1}(V)$ is open, then $V = f(f^{-1}(V))$ is open. The closed case is the same with closed sets, using $f^{-1}(Y \setminus V) = X \setminus f^{-1}(V)$. □

Example 18.4.11.

1. The *unit sphere* $S^n = \{x \in \mathbb{R}^{n+1} : \|x\|_2 = 1\}$ is a subspace of $\mathbb{R}^{n+1}$, and the *real projective space* is $\mathbb{RP}^n = S^n/(x \sim -x)$.
2. The *cylinder* and the *torus* are the quotients of $[0,1]^2$ identifying $(0,t) \sim (1,t)$, respectively identifying in addition $(s,0) \sim (s,1)$. The *cone* on X is $(X \times [0,1])/(X \times \{1\})$.
3. Two spaces X, Y with a subspace $A \subseteq X$ and a continuous map $f\colon A \to Y$ give the *adjunction space* $X \cup_f Y = (X \sqcup Y)/(a \sim f(a))$, the space obtained by *attaching* X to Y along f. These are the building blocks of CW complexes (Chapter 19).

Counterexample 18.4.12. Quotients of Hausdorff spaces need not be Hausdorff.

1. Let $x \sim y$ on $\mathbb{R}$ if $x - y \in \mathbb{Q}$. If $V \subseteq \mathbb{R}/\!\sim$ is open and nonempty, then $W = q^{-1}(V)$ is a nonempty open set with $W + \mathbb{Q} = W$. Its complement is closed and invariant under translation by $\mathbb{Q}$; if it contained a point y it would contain the dense set $y + \mathbb{Q}$, hence be all of $\mathbb{R}$. So $W = \mathbb{R}$, and the quotient is indiscrete.
2. (The line with two origins.) Let $X = (\mathbb{R} \times \{1,2\})/\!\sim$ with $(t,1) \sim (t,2)$ for $t \neq 0$. The projection q is open, since for U open $q^{-1}(q(U))$ is the union of U and the swap of $U \setminus (\{0\} \times \{1,2\})$; so q restricts to homeomorphisms of each copy of $\mathbb{R}$ onto open subsets, and every point of X has an open neighbourhood homeomorphic to $\mathbb{R}$. But the two origins $q(0,1)$ and $q(0,2)$ have no disjoint neighbourhoods, since preimages of neighbourhoods contain $(-\varepsilon, \varepsilon) \times \{1\}$ and $(-\varepsilon, \varepsilon) \times \{2\}$, whose images share $q(\varepsilon/2, 1)$.

18.5 Connectedness

Definition 18.5.1. A space X is *connected* if it is nonempty and is not the union of two disjoint nonempty open subsets. A subset is connected if it is connected as a subspace.

Lemma 18.5.2. *For a nonempty space X the following are equivalent: X is connected; the only subsets of X that are both open and closed are $\emptyset$ and X; every continuous map from X to the discrete space $\{0,1\}$ is constant.*

Proof. A decomposition $X = U \sqcup V$ into disjoint open sets is the same as a set $U = X \setminus V$ that is open and closed, and the same as the continuous map equal to 0 on U and 1 on V. □

Theorem 18.5.3. *A nonempty subset $I \subseteq \mathbb{R}$ is connected if and only if it is an interval: $a, b \in I$ and $a < c < b$ imply $c \in I$.*

Proof. If I is not an interval, with $a, b \in I$, $a < c < b$ and $c \notin I$, then $I \cap (-\infty, c)$ and $I \cap (c, \infty)$ disconnect I.

Let I be an interval and suppose $I = U \sqcup V$ with U, V nonempty and open in I. Choose $a \in U$ and $b \in V$; exchanging the roles of U and V if necessary, $a < b$. Then $[a,b] \subseteq I$. Let $s = \sup(U \cap [a,b])$, which exists by completeness of $\mathbb{R}$, and $s \in [a,b] \subseteq I$. Suppose $s \in U$.

Then $s < b$, and since U is open in I there is $\varepsilon > 0$ with $(s-\varepsilon, s+\varepsilon) \cap I \subseteq U$; the points of $(s, \min(s+\varepsilon, b))$ lie in $U \cap [a,b]$, contradicting the definition of s. Suppose $s \in V$. Then $s > a$, and there is $\varepsilon > 0$ with $(s-\varepsilon, s+\varepsilon) \cap I \subseteq V$. So $U \cap [a,b] \subseteq [a, \max(a, s-\varepsilon)]$, whose supremum is smaller than s, again a contradiction. □

Proposition 18.5.4. *1. Continuous images of connected spaces are connected.*

2. *If (A_i) is a family of connected subsets of X with a common point, then $\bigcup_i A_i$ is connected.*

3. *If $A \subseteq X$ is connected and $A \subseteq B \subseteq \overline{A}$, then B is connected.*

4. *A product of connected spaces is connected.*

Proof. We use Lemma 18.5.2. (1) If $f : X \to Y$ is surjective and $h : Y \to \{0,1\}$ is continuous, then hf is constant, so h is. (2) A continuous map $\bigcup_i A_i \to \{0,1\}$ is constant on each A_i, with the value it takes at the common point. (3) A continuous $h : B \to \{0,1\}$ is constant, say equal to c, on A; then $h^{-1}(c)$ is closed in B and contains A, so it contains the closure of A in B, which is B. (4) For two factors, fix (x_0, y_0). For each y, the set $(X \times \{y\}) \cup (\{x_0\} \times Y)$ is connected by (2), both pieces being homeomorphic to X or Y and sharing (x_0, y). All these sets contain (x_0, y_0) and cover $X \times Y$, so (2) applies; by induction finite products are connected. For an arbitrary product, fix a point a and let D be the set of points that differ from a in finitely many coordinates. For each finite set F of indices, the points agreeing with a outside F form a subspace homeomorphic to $\prod_{i \in F} X_i$, which is connected and contains a; so D is connected by (2). Every basic open set of Proposition 18.4.7(1) meets D, so D is dense and the product is connected by (3). □

Corollary 18.5.5 (Intermediate value theorem)**.** *If X is connected and $f : X \to \mathbb{R}$ is continuous, then $f(X)$ is an interval. In particular, a continuous $f : [a,b] \to \mathbb{R}$ takes every value between $f(a)$ and $f(b)$.*

Proof. Combine Theorem 18.5.3 and Proposition 18.5.4(1). □

Definition 18.5.6. The *connected component* of $x \in X$ is the union of all connected subsets containing x. A *path* from x to y is a continuous map $\gamma : [0,1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$. The space X is *path-connected* if it is nonempty and any two points are joined by a path. It is *locally connected* (*locally path-connected*) if every neighbourhood of every point contains a connected (path-connected) open neighbourhood.

Proposition 18.5.7. *1. The connected components are connected, closed, and partition X. In a locally connected space they are open.*

2. *Path-connected spaces are connected. The relation "joined by a path" is an equivalence relation, whose classes are the* path components*.*

3. *In a locally path-connected space the path components are open, and they coincide with the connected components. In particular, a connected open subset of $\mathbb{R}^n$ is path-connected.*

Proof. (1) The component C of x is connected by Proposition 18.5.4(2), and $\overline{C}$ is connected by (3), so $C = \overline{C}$. If two components meet, their union is connected, so they are equal. If X is locally connected and $y \in C$, a connected open neighbourhood of y lies in the component of y, which is C.

(2) If γ is a path from x to y and δ one from y to z, then $\gamma * \delta$, equal to $\gamma(2t)$ on $[0, 1/2]$ and to $\delta(2t-1)$ on $[1/2, 1]$, is continuous by the pasting lemma (Lemma 18.4.5); reversing $t \mapsto 1-t$ gives symmetry. If X is path-connected and $x \in X$, then X is the union of the images

of paths starting at x, which are connected by Theorem 18.5.3 and Proposition 18.5.4(1), so X is connected by Proposition 18.5.4(2).

(3) If y lies in the path component P and U is a path-connected open neighbourhood of y, then $U \subseteq P$; so path components are open. Each connected component C is the disjoint union of the path components it contains, which are open; by connectedness there is only one. Open balls in $\mathbb{R}^n$ are path-connected (use straight segments), so open subsets of $\mathbb{R}^n$ are locally path-connected. □

Counterexample 18.5.8 (Topologist's sine curve)**.** Connected does not imply path-connected. Let $f : (0, 1] \to [-1, 1]$ be the continuous function with $f(1/n) = (-1)^n$ for $n \geq 1$ that is affine on each interval $[1/(n+1), 1/n]$ (continuous by the pasting lemma applied on the open sets $(1/(n+1), 1/(n-1))$ and $(1/2, 1]$); classically one uses $\sin(1/x)$ instead. Let G be its graph and $T = G \cup (\{0\} \times [-1, 1]) \subseteq \mathbb{R}^2$. The map $x \mapsto (x, f(x))$ is continuous, so G is connected. By Corollary 18.5.5, for each $y \in [-1, 1]$ and n there is $x_n \in [1/(n+1), 1/n]$ with $f(x_n) = y$, and $(x_n, y) \to (0, y)$; so $G \subseteq T \subseteq \overline{G}$ and T is connected.

Suppose $\gamma = (x, y) \colon [0, 1] \to T$ is a path from $(0, 0)$ to $(1, f(1))$. The set of t with $x(t) = 0$ is closed and contains 0; let t_0 be its largest element, so $t_0 < 1$ and $\gamma(t) \in G$ for $t > t_0$. By continuity there is $\delta > 0$ with $t_0 + \delta \leq 1$ and $|y(t) - y(t_0)| < 1/2$ for $t \in [t_0, t_0 + \delta]$. Let $u = x(t_0 + \delta) > 0$ and choose n with $1/n < u$. By Corollary 18.5.5 there are $t, t' \in (t_0, t_0 + \delta]$ with $x(t) = 1/n$ and $x(t') = 1/(n+1)$, so $y(t)$ and $y(t')$ are 1 and -1 in some order; both lie within $1/2$ of $y(t_0)$, which is impossible.

Example 18.5.9. $\mathbb{R}$ and $\mathbb{R}^2$ are not homeomorphic. A homeomorphism would restrict to a homeomorphism between $\mathbb{R} \setminus \{a\}$, which is not connected, and $\mathbb{R}^2 \setminus \{b\}$, which is path-connected: two points $p, q \neq b$ are joined by the segment $[p, q]$ if it avoids b, and otherwise by the segments $[p, r]$ and $[r, q]$ for any r not on the line through p and q. Similarly S^n is path-connected for $n \geq 1$, being a continuous image of $\mathbb{R}^{n+1} \setminus \{0\}$ under $x \mapsto x/\|x\|_2$.

18.6 Compactness

Definition 18.6.1. An *open cover* of a space X is a family of open sets whose union is X. The space X is *compact* if every open cover has a finite subcover. A subset is compact if it is compact as a subspace, that is, if every cover of it by open subsets of X has a finite subcover.

Compactness is the topological substitute for finiteness: many statements about finite sets, such as "a real function on it has a maximum", extend to compact spaces, because one can reduce to finitely many open sets. To prove that a space is *not* compact one exhibits a single open cover without finite subcover; to prove that it is compact one has to handle every cover.

Example 18.6.2.

1. Every finite space is compact, and so is every space with finitely many open sets. An infinite discrete space is not: the singletons cover it.

2. $(0, 1]$ is not compact: the open sets $(\frac{1}{n}, 1]$ cover it, and finitely many of them have union $(\frac{1}{N}, 1]$ for the largest N used, which misses $\frac{1}{2N}$. Likewise $\mathbb{R}$ is not compact (cover by $(-n, n)$), and $\mathbb{Q} \cap [0, 1]$ is not (cover by the sets $\{q : |q - \alpha| > \frac{1}{n}\}$ for an irrational $\alpha \in (0, 1)$).

3. $K = \{0\} \cup \{\frac{1}{n} : n \geq 1\}$ is compact: given an open cover, some member U contains 0, hence all $\frac{1}{n}$ with $n > N$ for some N, and finitely many further members cover $1, \frac{1}{2}, \ldots, \frac{1}{N}$. A convergent sequence together with its limit is always compact, by the same argument.

4. Every set with the cofinite topology is compact: one member of a cover misses only finitely many points, each of which lies in some member.

5. In a non-Hausdorff space compact sets need not be closed: in the Sierpiński space $\{1\}$ is compact but not closed, and in an indiscrete space every subset is compact.

Proposition 18.6.3. *1. A closed subset of a compact space is compact.*

2. In a Hausdorff space, disjoint compact subsets K, L have disjoint open neighbourhoods; in particular compact subsets are closed.

3. Continuous images of compact spaces are compact.

4. A continuous map from a compact space to a Hausdorff space is closed. If it is bijective, it is a homeomorphism; if it is injective, it is an embedding; if it is surjective, it is a quotient map.

Proof. (1) An open cover of $C \subseteq X$, together with $X \setminus C$, covers X. (2) First let $L = \{y\}$. For each $k \in K$ choose disjoint open $U_k \ni k$ and $V_k \ni y$; finitely many $U_{k_1}, \dots, U_{k_m}$ cover K, and $U = \bigcup_j U_{k_j}$ and $V = \bigcap_j V_{k_j}$ are disjoint. For general L, do this for each $y \in L$ and use a finite subcover of L by the resulting V's in the same way. (3) Preimages of an open cover of $f(X)$ cover X. (4) Closed subsets are compact by (1), their images are compact by (3), hence closed by (2). A closed continuous bijection has continuous inverse; for an injection apply this to $X \to f(X)$, and for a surjection use Proposition 18.4.10. □

Proposition 18.6.4. *If X and Y are compact, so is $X \times Y$.*

Proof. Let $\mathcal{W}$ be an open cover of $X \times Y$ and fix $y \in Y$. For each $x \in X$ choose $W_x \in \mathcal{W}$ containing (x, y) and a basic open set $U_x \times V_x$ with $(x, y) \in U_x \times V_x \subseteq W_x$. Finitely many $U_{x_1}, \dots, U_{x_m}$ cover X; let $N_y = \bigcap_j V_{x_j}$. Then $X \times N_y$ is covered by $W_{x_1}, \dots, W_{x_m}$ (the *tube lemma*). Finitely many N_y cover Y, and the corresponding finitely many members of $\mathcal{W}$ cover $X \times Y$. □

Theorem 18.6.5 (Heine–Borel)**.** *Every closed bounded interval $[a, b] \subseteq \mathbb{R}$ is compact. A subset of $\mathbb{R}^n$ (or $\mathbb{C}^n = \mathbb{R}^{2n}$) is compact if and only if it is closed and bounded.*

Proof. Let $\mathcal{U}$ be an open cover of $[a, b]$ and S the set of $t \in [a, b]$ such that $[a, t]$ is covered by finitely many members. Then $a \in S$; let $s = \sup S$. Choose $U \in \mathcal{U}$ with $s \in U$ and $\varepsilon > 0$ with $(s - \varepsilon, s + \varepsilon) \cap [a, b] \subseteq U$, and $t \in S$ with $t > s - \varepsilon$. A finite cover of $[a, t]$ together with U covers $[a, t']$ for $t' = \min(s + \varepsilon/2, b)$, so $t' \in S$ and $t' \leq s$. Hence $s = b \in S$.

For the second statement, a compact $K \subseteq \mathbb{R}^n$ is closed by Proposition 18.6.3(2) and bounded, since the balls $B(0, m)$ cover it. A closed bounded set lies in some cube $[-R, R]^n$, which is compact as a finite product of compact spaces by Proposition 18.6.4 (with the product topology, which is the Euclidean one by Proposition 18.4.7(4)); so it is compact by Proposition 18.6.3(1). □

Corollary 18.6.6 (Extreme value theorem)**.** *A continuous function $f : X \to \mathbb{R}$ on a nonempty compact space attains a maximum and a minimum.*

Proof. $f(X)$ is compact, hence closed and bounded, so it contains its supremum and infimum, which lie in its closure. □

Lemma 18.6.7 (Alexander subbasis lemma)**.** *Let $\mathcal{S}$ be a subbasis of the topology of X. If every cover of X by members of $\mathcal{S}$ has a finite subcover, then X is compact.*

Proof. Suppose not. The set of open covers of X without finite subcover is nonempty, and ordered by inclusion every chain in it has an upper bound, its union: a finite subcover of the union would lie in one member of the chain. By Zorn's lemma (Theorem 3.7.2) there is a maximal open cover C without finite subcover. The members of $C \cap \mathcal{S}$ do not cover X, since otherwise they would have a finite subcover. Choose x not covered by them and $U \in C$ with $x \in U$. There are $S_1, \dots, S_k \in \mathcal{S}$ with $x \in S_1 \cap \cdots \cap S_k \subseteq U$, and no S_j belongs to C. By maximality, $C \cup \{S_j\}$ has a finite subcover, so $X = S_j \cup Y_j$ with Y_j a finite union of members of C. Then $X = (S_1 \cap \cdots \cap S_k) \cup Y_1 \cup \cdots \cup Y_k \subseteq U \cup Y_1 \cup \cdots \cup Y_k$ is covered by finitely many members of C, a contradiction. (If $k = 0$, then $U = X$ is itself a finite subcover.) □

Theorem 18.6.8 (Tychonoff)**.** *Every product of compact spaces is compact.*

Proof. Let $X = \prod_i X_i$. If some X_i is empty, so is X. Otherwise, by Lemma 18.6.7 it suffices to consider a cover $\mathcal{S}$ of X by subbasic sets $p_i^{-1}(U)$. For each i let $\mathcal{U}_i$ be the set of open $U \subseteq X_i$ with $p_i^{-1}(U) \in \mathcal{S}$. If for some i the family $\mathcal{U}_i$ covers X_i, then a finite subcover of $\mathcal{U}_i$ gives a finite subcover of $\mathcal{S}$. Otherwise choose, by the axiom of choice, $x_i \in X_i$ not covered by $\mathcal{U}_i$ for each i; then the point $(x_i)_i$ is not covered by $\mathcal{S}$, a contradiction. □

Remark 18.6.9. Tychonoff's theorem implies the axiom of choice over ZF [Kel50], so the use of choice in its proof cannot be avoided.

Example 18.6.10. The sphere S^n is compact by Theorem 18.6.5, and so is $\mathbb{RP}^n$, a continuous image of S^n. The quotient $[0,4]/\{0,4\}$ is homeomorphic to S^1. Indeed, let $Q = \{x \in \mathbb{R}^2 : \|x\|_\infty = 1\}$ be the boundary of the square. The maps $x \mapsto x/\|x\|_2$ and $x \mapsto x/\|x\|_\infty$ are mutually inverse continuous maps $Q \to S^1$ and $S^1 \to Q$. The map $[0,4] \to Q$ running affinely along the four sides, from $(1,-1)$ to $(1,1)$, $(-1,1)$, $(-1,-1)$ and back, is a continuous surjection identifying only 0 and 4; the induced continuous bijection $[0,4]/\{0,4\} \to Q$ from a compact space to a Hausdorff space is a homeomorphism by Proposition 18.6.3(4).

Counterexample 18.6.11.

1. An infinite set X with the metric $d(x,y) = 1$ for $x \neq y$ is closed and bounded in itself but not compact: its topology is discrete, and the cover by singletons has no finite subcover.

2. In the cofinite topology on $\mathbb{N}$ every subset is compact (any member of a cover contains all but finitely many points), and the set of even numbers is compact but not closed. Hausdorffness in Proposition 18.6.3(2) is needed.

18.7 Complete and compact metric spaces

Definition 18.7.1. A sequence (x_n) in a metric space is *Cauchy* if for every $\varepsilon > 0$ there is N with $d(x_m, x_n) < \varepsilon$ for $m, n \geq N$. The space is *complete* if every Cauchy sequence converges. It is *totally bounded* if for every $\varepsilon > 0$ it is covered by finitely many balls of radius ε. A *Banach space* is a normed space that is complete for the metric of its norm.

Proposition 18.7.2.

1. *$\mathbb{R}^n$ and $\mathbb{C}^n$ are complete, and so are all their closed subsets.*

2. *A complete subspace of a metric space is closed; a closed subspace of a complete space is complete.*

3. *For a nonempty set X and a complete metric space (Y,d), the set $B(X,Y)$ of maps with bounded image, with $d_\infty(f,g) = \sup_x d(f(x),g(x))$, is a complete metric space. If X is a space, the subset $C_b(X,Y)$ of continuous maps is closed, hence complete. In particular $C_b(X,\mathbb{K})$ with the norm $\|f\|_\infty = \sup|f|$ is a Banach space.*

Proof. (2) If $A \subseteq X$ is complete and $x \in \overline{A}$, a sequence in A converging to x (Proposition 18.3.5) is Cauchy, so it converges in A, and by uniqueness of limits $x \in A$. If X is complete and A closed, a Cauchy sequence in A converges in X, and its limit lies in $\overline{A} = A$.

(1) With the maximum norm, a sequence is Cauchy if and only if each coordinate sequence is, and converges if and only if each coordinate does. Real Cauchy sequences converge by Proposition 4.7.6, and complex ones because real and imaginary parts are Cauchy. The second part follows from (2).

(3) For bounded f, g, $d_\infty(f, g)$ is finite by the triangle inequality, and d_∞ is a metric. Let (f_n) be Cauchy. For each x, $(f_n(x))$ is Cauchy in Y; let $f(x)$ be its limit. Given $\varepsilon > 0$ choose N with $d(f_n(x), f_m(x)) < \varepsilon$ for all x and $m, n \geq N$. Since $|d(a,b) - d(a,c)| \leq d(b,c)$, letting $m \to \infty$ gives $d(f_n(x), f(x)) \leq \varepsilon$ for all x and $n \geq N$. So f is bounded and $f_n \to f$ in d_∞. Uniform limits of continuous maps are continuous (Proposition 18.3.10), so $C_b(X, Y)$ is closed. □

Lemma 18.7.3 (Lebesgue number lemma)**.** *Let X be a metric space in which every sequence has a convergent subsequence, and $\mathcal{U}$ an open cover. There is $\delta > 0$ such that every ball of radius δ is contained in some member of $\mathcal{U}$.*

Proof. Otherwise choose x_n such that $B(x_n, 1/n)$ lies in no member of $\mathcal{U}$, and a subsequence $x_{n_k} \to x$. Let $x \in U \in \mathcal{U}$ and $B(x, 2\varepsilon) \subseteq U$. For k large, $d(x_{n_k}, x) < \varepsilon$ and $1/n_k < \varepsilon$, so $B(x_{n_k}, 1/n_k) \subseteq B(x, 2\varepsilon) \subseteq U$, a contradiction. □

Theorem 18.7.4. *For a metric space X the following are equivalent:*

1. *X is compact;*
2. *every sequence in X has a convergent subsequence (X is* sequentially compact*);*
3. *X is complete and totally bounded.*

Proof. (1)⇒(2): Let (x_n) have no convergent subsequence. Then every $x \in X$ has an open ball containing x_n for only finitely many n: otherwise we could choose $n_1 < n_2 < \cdots$ with $d(x_{n_k}, x) < 1/k$. Finitely many such balls cover X, but together they contain x_n for only finitely many n, a contradiction.

(2)⇒(3): A Cauchy sequence with a convergent subsequence converges to the same limit. If X were not totally bounded, for some $\varepsilon > 0$ we could choose inductively $x_n \notin \bigcup_{m<n} B(x_m, \varepsilon)$; this sequence has no Cauchy subsequence.

(3)⇒(2): Let (x_n) be a sequence. Cover X by finitely many balls of radius 1; one of them contains x_n for infinitely many n. Among these indices, cover by balls of radius $1/2$ and choose again, and so on; this gives nested infinite index sets $N_1 \supseteq N_2 \supseteq \cdots$ such that $d(x_m, x_n) < 2/k$ for $m, n \in N_k$. Choosing $n_k \in N_k$ increasing gives a Cauchy subsequence, which converges.

(2)⇒(1): Let $\mathcal{U}$ be an open cover and δ a Lebesgue number (Lemma 18.7.3). By (2)⇒(3), X is covered by finitely many balls of radius δ, each contained in a member of $\mathcal{U}$. □

Corollary 18.7.5. *A continuous map $f : X \to Y$ from a compact metric space to a metric space is* uniformly continuous*: for every $\varepsilon > 0$ there is $\delta > 0$ such that $d(x, x') < \delta$ implies $d(f(x), f(x')) < \varepsilon$.*

Proof. Let δ be a Lebesgue number of the cover by the sets $f^{-1}(B(y, \varepsilon/2))$. If $d(x, x') < \delta$, then $x, x' \in B(x, \delta)$ lie in one such set, so $d(f(x), f(x')) < \varepsilon$. □

Theorem 18.7.6 (Banach fixed point theorem, Banach–Caccioppoli)**.** *Let X be a nonempty complete metric space and $T : X \to X$ a* contraction*: $d(Tx, Ty) \leq c\, d(x, y)$ for some $0 \leq c < 1$. Then T has a unique fixed point, and for every x_0 the sequence $x_{n+1} = Tx_n$ converges to it.*

Proof. By induction $d(x_{n+1}, x_n) \le c^n d(x_1, x_0)$, so for $m > n$, $d(x_m, x_n) \le \sum_{k=n}^{m-1} c^k d(x_1, x_0) = c^n \frac{1-c^{m-n}}{1-c} d(x_1, x_0) \le \frac{c^n}{1-c} d(x_1, x_0)$. Since $c^n \to 0$ (if $c > 0$, write $1/c = 1 + h$ with $h > 0$; then $c^{-n} \ge 1 + nh$), the sequence is Cauchy; let x be its limit. A contraction is continuous, so $Tx = \lim Tx_n = \lim x_{n+1} = x$. If also $Ty = y$, then $d(x, y) \le c\, d(x, y)$, so $x = y$. □

The theorem is also called the *contraction mapping principle*, and, especially in Italy, the *Banach–Caccioppoli theorem*: Banach proved it in his 1922 thesis, and Caccioppoli found it independently in 1930. Letting $m \to \infty$ in the proof gives the error estimate $d(x_n, x) \le \frac{c^n}{1-c} d(x_1, x_0)$, which says how many iterations are needed for a given accuracy before the fixed point is known. Each hypothesis is needed: a translation $x \mapsto x + 1$ of $\mathbb{R}$ satisfies $d(Tx, Ty) = d(x, y)$ and has no fixed point; $x \mapsto x/2$ on the incomplete space $(0, 1]$ is a contraction without fixed point; and the following example shows that $d(Tx, Ty) < d(x, y)$ for $x \ne y$ is not enough.

Counterexample 18.7.7. Let $X = [1, \infty)$, complete as a closed subset of $\mathbb{R}$, and $T(x) = x + 1/x$. Then $T(X) \subseteq X$, and for $1 \le x < y$, $T(y) - T(x) = (y - x)\big(1 - \frac{1}{xy}\big)$, so $0 \le T(y) - T(x) < y - x$. But $T(x) > x$ for all x, so T has no fixed point. The ratio $1 - 1/(xy)$ tends to 1 as $x, y \to \infty$, so no constant $c < 1$ works. On a *compact* metric space, however, a map with $d(Tx, Ty) < d(x, y)$ for $x \ne y$ does have a unique fixed point: the continuous function $x \mapsto d(x, Tx)$ attains its minimum at some x, and if $Tx \ne x$, then $d(Tx, T^2x) < d(x, Tx)$ contradicts minimality; uniqueness is as in the theorem.

Theorem 18.7.8 (Baire category theorem)**.** *In a complete metric space X, a countable intersection of dense open sets is dense. Equivalently, a countable union of closed sets with empty interior has empty interior.*

Proof. Let $U_1, U_2, \ldots$ be dense open and W nonempty open. Since $W \cap U_1$ is nonempty and open, it contains a ball $B(x_1, 2r_1)$ with $r_1 < 1$, and then the closed ball $\bar{B}(x_1, r_1) = \{y : d(x_1, y) \le r_1\}$. Inductively, $B(x_n, r_n) \cap U_{n+1}$ is nonempty and open, so it contains $\bar{B}(x_{n+1}, r_{n+1})$ with $r_{n+1} < 1/(n + 1)$. For $m \ge n$, $x_m \in B(x_n, r_n)$, so (x_n) is Cauchy; its limit x lies in every closed set $\bar{B}(x_n, r_n)$, hence in $W \cap \bigcap_n U_n$. The second statement is the first for the complements. □

Corollary 18.7.9. *A nonempty complete metric space in which no point is isolated (no singleton is open) is uncountable.*

Proof. If $X = \{x_1, x_2, \ldots\}$, then X is the countable union of the closed sets $\{x_n\}$, which have empty interior, contradicting Theorem 18.7.8. □

Counterexample 18.7.10. Completeness is not a topological property: $t \mapsto t/(1 - |t|)$ is a homeomorphism $(-1, 1) \to \mathbb{R}$ with inverse $s \mapsto s/(1 + |s|)$, but $(-1, 1)$ is not complete. And $\mathbb{Q}$, which is not complete, is a countable union of closed sets with empty interior, so the Baire category theorem fails for it.

18.8 Separation axioms, Urysohn and Tietze

Definition 18.8.1. A space X is T_1 if its points are closed. A T_1 space is *regular* if a point x and a closed set $C \not\ni x$ have disjoint open neighbourhoods, and *normal* if any two disjoint closed sets have disjoint open neighbourhoods. So normal $\Rightarrow$ regular $\Rightarrow$ Hausdorff $\Rightarrow T_1$.

Lemma 18.8.2. *A T_1 space X is normal if and only if for every closed C and open $U \supseteq C$ there is an open V with $C \subseteq V \subseteq \overline{V} \subseteq U$. It is regular if and only if this holds for C a point.*

Proof. If X is normal, separate C and $X \setminus U$ by disjoint open V and W; then $\overline{V} \subseteq X \setminus W \subseteq U$. Conversely, for disjoint closed C, D choose V for $U = X \setminus D$; then V and $X \setminus \overline{V}$ separate them. The regular case is identical. □

Proposition 18.8.3. *Metric spaces and compact Hausdorff spaces are normal.*

Proof. For a nonempty subset A of a metric space let $d(x, A) = \inf_{a \in A} d(x, a)$. Then $|d(x, A) - d(y, A)| \leq d(x, y)$, so $d(-, A)$ is continuous, and $d(x, A) = 0$ if and only if $x \in \overline{A}$. For disjoint nonempty closed A, B, the continuous function (Proposition 18.4.7(5)) $g(x) = d(x, A) - d(x, B)$ is negative on A and positive on B, so $\{g < 0\}$ and $\{g > 0\}$ separate them. For compact Hausdorff spaces use Propositions 18.6.3(1) and (2). □

Theorem 18.8.4 (Urysohn's lemma)**.** *Let A, B be disjoint closed subsets of a normal space X. There is a continuous $f : X \to [0, 1]$ with $f = 0$ on A and $f = 1$ on B.*

Proof. Let D be the set of dyadic rationals $k/2^n$ in $[0, 1]$. We construct open sets U_r, $r \in D$, with $A \subseteq U_0$, $U_1 = X \setminus B$ and $\overline{U_r} \subseteq U_s$ for $r < s$. Choose U_0 with $A \subseteq U_0 \subseteq \overline{U_0} \subseteq U_1$ by Lemma 18.8.2. If U_r is defined for all r with denominator 2^n, then for $r = (2k+1)/2^{n+1}$ choose U_r with $\overline{U_{k/2^n}} \subseteq U_r \subseteq \overline{U_r} \subseteq U_{(k+1)/2^n}$. The required inclusions for $r < s$ with denominators dividing 2^{n+1} follow: if one of them is new, pass through the neighbouring old index, and if both are new, there is an old index strictly between them.

Define $f(x) = \inf(\{r \in D : x \in U_r\} \cup \{1\})$. Then $f = 0$ on A, and $f = 1$ on B since B meets no U_r. If $x \in \overline{U_r}$, then $x \in U_s$ for all $s > r$ in D, so $f(x) \leq r$ by density of D. If $x \notin U_r$, then $x \notin U_s$ for $s \leq r$, so $f(x) \geq r$. Hence for $a \in \mathbb{R}$,

$$f^{-1}([0, a)) = \bigcup_{r \in D,\, r < a} U_r \quad (a \leq 1), \qquad f^{-1}((a, 1]) = \bigcup_{r \in D,\, r > a} (X \setminus \overline{U_r}) \quad (a \geq 0).$$

For the second equality, if $f(x) > a$ choose $r \in D$ with $a < r < f(x)$; then $x \notin \overline{U_r}$. These sets are open, and the intervals $[0, a)$, $(a, 1]$ form a subbasis of $[0, 1]$, so f is continuous. □

Theorem 18.8.5 (Tietze extension theorem)**.** *Let A be a closed subset of a normal space X. Every continuous $f : A \to [-1, 1]$ extends to a continuous $F : X \to [-1, 1]$, and every continuous $f : A \to \mathbb{R}$ extends to a continuous $F : X \to \mathbb{R}$.*

Proof. Step 1. If $g : A \to [-c, c]$ is continuous, there is a continuous $h : X \to [-c/3, c/3]$ with $|g - h| \leq 2c/3$ on A: the sets $g^{-1}([-c, -c/3])$ and $g^{-1}([c/3, c])$ are disjoint and closed in X, and Urysohn's lemma (rescaled) gives h equal to $-c/3$ on the first and $c/3$ on the second; check $|g - h| \leq 2c/3$ separately on the two sets and on the rest of A, where $|g| < c/3$.

Step 2. Put $g_0 = f$ and, given $g_n : A \to [-(2/3)^n, (2/3)^n]$, let h_n be as in Step 1 and $g_{n+1} = g_n - h_n|_A$. Then $|h_n| \leq \frac{1}{3}(\frac{2}{3})^n$, so $F = \sum_n h_n$ converges uniformly and is continuous by Proposition 18.3.10, with $|F| \leq \sum_n \frac{1}{3}(\frac{2}{3})^n = 1$. On A, $f - \sum_{n<N} h_n = g_N \to 0$, so $F|_A = f$.

Step 3. For $f : A \to \mathbb{R}$, compose with the homeomorphism $\mathbb{R} \to (-1, 1)$ of Counterexample 18.7.10 and extend to $F : X \to [-1, 1]$ by Step 2. The set $E = F^{-1}(\{-1, 1\})$ is closed and disjoint from A; by Urysohn's lemma choose $\varphi : X \to [0, 1]$ with $\varphi = 0$ on E and $\varphi = 1$ on A. Then φF extends f and takes values in $(-1, 1)$; compose back. □

Counterexample 18.8.6. Let $K = \{1/n : n \geq 1\}$ and give $\mathbb{R}$ the topology with basis the open intervals (a, b) and the sets $(a, b) \setminus K$ (the conditions of Lemma 18.2.10 are clear). It is finer than the standard topology, hence Hausdorff, and K is closed. Suppose $U \supseteq K$ and $V \ni 0$ are disjoint open sets. Since every interval around 0 meets K, V contains a set $(a, b) \setminus K$ with $a < 0 < b$. Choose n with $1/n < b$. The only basic sets containing $1/n$ are intervals, so $U \supseteq (c, d) \ni 1/n$, and $(c, d) \cap (a, b)$ contains points not in K, which lie in $U \cap V$. So this Hausdorff space is not regular.

Lemma 18.8.7 (Tychonoff)**.** *A regular space in which every open cover has a countable subcover (a* Lindelöf *space), for instance a regular second countable space, is normal.*

Proof. Let A, B be disjoint closed sets. For $a \in A$, regularity and Lemma 18.8.2 give an open $U \ni a$ with $\overline{U} \cap B = \emptyset$. As A is closed in a Lindelöf space, it is Lindelöf, so countably many such sets $U_1, U_2, \ldots$ cover A; similarly open $V_1, V_2, \ldots$ cover B with $\overline{V_k} \cap A = \emptyset$. Put $U_n' = U_n \setminus \bigcup_{k \le n} \overline{V_k}$ and $V_n' = V_n \setminus \bigcup_{k \le n} \overline{U_k}$, which are open, and $U' = \bigcup_n U_n'$, $V' = \bigcup_n V_n'$. Then $A \subseteq U'$, since a point of A lies in some U_n and in no $\overline{V_k}$; similarly $B \subseteq V'$. If $x \in U_n' \cap V_m'$ with $n \le m$, then $x \in U_n$ but $x \notin \overline{U_n}$, a contradiction, and the case $n > m$ is symmetric. So $U' \cap V' = \emptyset$. Second countable spaces are Lindelöf by Proposition 18.3.12. □

Theorem 18.8.8 (Urysohn metrisation theorem)**.** *Every regular second countable space is metrisable: its topology is induced by a metric.*

Proof. Let X be regular with a countable basis (B_n); by Lemma 18.8.7 it is normal. For each pair (n, m) with $\overline{B_n} \subseteq B_m$ choose, by Urysohn's lemma (Theorem 18.8.4), a continuous $f_{n,m} \colon X \to [0,1]$ equal to 1 on $\overline{B_n}$ and to 0 outside B_m. Enumerate these functions as $f_1, f_2, \ldots$. They separate points from closed sets: if $x \in U$ with U open, choose m with $x \in B_m \subseteq U$, and by regularity and Lemma 18.8.2 an open V with $x \in V \subseteq \overline{V} \subseteq B_m$, and then n with $x \in B_n \subseteq V$; the corresponding f_k has $f_k(x) = 1$ and vanishes outside U.

Define $d(x,y) = \sum_k 2^{-k} |f_k(x) - f_k(y)|$. It is symmetric and satisfies the triangle inequality, and $d(x,y) > 0$ for $x \neq y$, because X is T_1, so $X \setminus \{y\}$ is an open neighbourhood of x, and some f_k equals 1 at x and vanishes outside it, so $f_k(x) = 1 \neq 0 = f_k(y)$. Each $d(x,-)$ is continuous, being a uniformly convergent series of continuous functions (Proposition 18.3.10), so d-balls are open. Conversely, if $x \in U$ with U open and f_k is as above, then $d(x,y) < 2^{-k}$ implies $|f_k(y) - 1| < 1$, so $f_k(y) > 0$ and $y \in U$: the d-ball of radius 2^{-k} about x lies in U. So d induces the topology of X. □

Remark 18.8.9. Topological manifolds are regular (indeed locally compact Hausdorff) and second countable, hence metrisable (Chapter 20). Regularity cannot be weakened to the Hausdorff property: the space of Counterexample 18.8.6 is second countable (a basis is given by the intervals with rational endpoints and their differences with K) and Hausdorff, but not regular, hence not metrisable, since metric spaces are normal (Proposition 18.8.3).

18.8.1 The hierarchy of separation axioms

The axioms T_1, Hausdorff, regular and normal are part of a longer list, traditionally numbered T_0 to T_6, each asking for more ways to separate points and sets by open sets or by functions. One of them is what makes the Stone–Čech compactification work (Section 18.13), and two others strengthen normality in the direction of metric spaces.

Definition 18.8.10. A space X is

1. T_0 if for any two distinct points some open set contains exactly one of them;
2. *completely regular*, or a *Tychonoff space*, or $T_{3\frac{1}{2}}$, if it is T_1 and for every closed $C \subseteq X$ and $x \notin C$ there is a continuous $f \colon X \to [0,1]$ with $f(x) = 0$ and $f = 1$ on C;
3. *completely normal*, or T_5, if every subspace of X is normal;
4. *perfectly normal*, or T_6, if it is normal and every closed set is a countable intersection of open sets.

With T_2 = Hausdorff, T_3 = regular and T_4 = normal, as in Definition 18.8.1.

Proposition 18.8.11. *1. $T_4 \Rightarrow T_{3\frac{1}{2}} \Rightarrow T_3 \Rightarrow T_2 \Rightarrow T_1 \Rightarrow T_0$, and $T_5 \Rightarrow T_4$.*

2. Metric spaces are completely normal and perfectly normal.

3. Subspaces of T_0, T_1, T_2, T_3 and $T_{3\frac{1}{2}}$ spaces have the same property, and so do closed subspaces of normal spaces.

4. Products of T_1 spaces are T_1, and products of completely regular spaces are completely regular.

Proof. (1) A normal space is completely regular by Urysohn's lemma (Theorem 18.8.4), applied to $\{x\}$ and C. If f separates x from C as in the definition, the open sets $\{f < \frac{1}{2}\}$ and $\{f > \frac{1}{2}\}$ separate them; so completely regular spaces are regular. The remaining implications were noted in Definition 18.8.1, except $T_1 \Rightarrow T_0$, which is clear ($X \setminus \{y\}$ contains x but not y), and $T_5 \Rightarrow T_4$, as X is a subspace of itself.

(2) Subspaces of metric spaces are metric spaces, hence normal (Proposition 18.8.3). A closed set $A \neq \emptyset$ is the intersection of the open sets $\{x : d(x, A) < 1/n\}$, as $d(x, A) = 0$ exactly for $x \in \overline{A} = A$; and $\emptyset = \bigcap_n \emptyset$.

(3) Let $Y \subseteq X$. For T_0, T_1, T_2 intersect the separating open sets with Y. If $C \subseteq Y$ is closed in Y and $x \in Y \setminus C$, then $x \notin \overline{C}$ (closure in X), because $\overline{C} \cap Y = C$; separating x from $\overline{C}$ in X by open sets or by a function and restricting to Y gives the regular and completely regular cases. A closed subset of a closed subspace is closed in X, which gives the last statement.

(4) In a product of T_1 spaces, $\{x\} = \bigcap_i p_i^{-1}(\{x_i\})$ is closed. Let $C \subseteq \prod_i X_i$ be closed and $x \notin C$. Choose a basic open set $\prod_i U_i \ni x$ disjoint from C, with $U_i = X_i$ except for $i \in \{i_1, \dots, i_k\}$, and continuous $f_j \colon X_{i_j} \to [0, 1]$ with $f_j(x_{i_j}) = 0$ and $f_j = 1$ outside U_{i_j}. Then $f = \max_j f_j \circ p_{i_j}$ is continuous, $f(x) = 0$, and if $y \in C$, then $y \notin \prod_i U_i$, so $y_{i_j} \notin U_{i_j}$ for some j and $f(y) = 1$. (For $k = 0$, C is empty and $f = 0$ works.) □

All implications in (1) are strict. The Sierpiński space (Example 18.2.2) is T_0 but not T_1; an infinite set with the cofinite topology is T_1 but not Hausdorff (Counterexample 18.2.19); Counterexample 18.8.6 is Hausdorff but not regular; and below we show that the Sorgenfrey plane is completely regular but not normal. There are also regular spaces that are not completely regular, normal spaces that are not completely normal (for instance a compact Hausdorff space, the *Tychonoff plank*, has a non-normal open subspace), and completely normal spaces that are not perfectly normal [Eng89]; these examples need ordinals or more elaborate constructions. By (3) and (4), normality is the one axiom in the list that is not inherited by subspaces and products; this is why completely regular spaces, and not normal ones, are the natural class for many purposes.

The tool for proving non-normality is a counting argument.

Lemma 18.8.12 (Jones's lemma)**.** *Let X be a separable normal space and $D \subseteq X$ a closed subset whose subspace topology is discrete. Then $2^{|D|} \leq 2^{\aleph_0}$. In particular $|D| < 2^{\aleph_0}$.*

Proof. Let Q be a countable dense subset. Every subset $A \subseteq D$ is closed in D, which is discrete, hence closed in X, and so is $D \setminus A$. By normality and Lemma 18.8.2 choose an open $U_A \supseteq A$ with $\overline{U_A} \cap (D \setminus A) = \emptyset$. The map $A \mapsto U_A \cap Q$ from $\mathcal{P}(D)$ to $\mathcal{P}(Q)$ is injective: if $A \neq B$, say $a \in A \setminus B$, then $a \in U_A$ and $a \in D \setminus B$, so $a \notin \overline{U_B}$; the open set $U_A \setminus \overline{U_B}$ contains a, so it contains a point of Q, which lies in $U_A \cap Q$ but not in $U_B \cap Q$. So $2^{|D|} \leq 2^{|Q|} \leq 2^{\aleph_0}$. If $|D| \geq 2^{\aleph_0}$, Cantor's theorem (Theorem 3.6.3) would give $2^{|D|} > |D| \geq 2^{\aleph_0}$. □

Example 18.8.13. Let S be the Sorgenfrey line (Counterexample 18.3.13).

1. *S is normal.* Its topology is finer than the Euclidean one, so points are closed. Let A, B be disjoint closed sets. For $a \in A$ choose $x_a > a$ with $[a, x_a) \cap B = \emptyset$, and for $b \in B$ choose $y_b > b$ with $[b, y_b) \cap A = \emptyset$. Then $U = \bigcup_a [a, x_a)$ and $V = \bigcup_b [b, y_b)$ are open neighbourhoods of A and B, and they are disjoint: if $[a, x_a)$ meets $[b, y_b)$ and $a < b$, then $b \in [a, x_a)$, which misses B; if $b < a$, then $a \in [b, y_b)$, which misses A.

2. *The Sorgenfrey plane $S \times S$ is completely regular.* The sets $[a, b)$ are open and closed in S (the complement $(-\infty, a) \cup [b, \infty)$ is a union of half-open intervals), so the basic open sets $W = [a, b) \times [c, d)$ of $S \times S$ are open and closed. It is T_1 by Proposition 18.8.11(4). If $x \notin C$ with C closed, choose such a W with $x \in W \subseteq (S \times S) \setminus C$; the indicator function of the complement of W is continuous, 0 at x and 1 on C.

3. *$S \times S$ is not normal.* It is separable, as $\mathbb{Q} \times \mathbb{Q}$ meets every $[a, b) \times [c, d)$. The antidiagonal $L = \{(x, -x) : x \in \mathbb{R}\}$ is closed, being closed in the coarser Euclidean topology, and discrete: $[x, x+1) \times [-x, -x+1)$ meets L only in $(x, -x)$, since $(y, -y)$ in it has $y \geq x$ and $-y \geq -x$. As $|L| = |\mathbb{R}| = 2^{\aleph_0}$ (Proposition 4.8.6), Jones's lemma shows that $S \times S$ is not normal.

So a product of two normal spaces need not be normal, and $S \times S$ is completely regular but not normal. The subspace L is also an uncountable discrete subspace of a separable space; so subspaces of separable spaces need not be separable.

18.8.2 Separability

Separability, the existence of a countable dense set, is the countability condition that survives the most operations. For metric spaces it is equivalent to the others.

Proposition 18.8.14. *1. A metric space is separable if and only if it is second countable, if and only if it is Lindelöf.*

2. Continuous images and open subspaces of separable spaces are separable, and subspaces of separable metric spaces are separable.

Proof. (1) By Proposition 18.3.12, separable metric spaces are second countable and second countable spaces are Lindelöf. If X is Lindelöf, for each n the cover by all balls $B(x, 1/n)$ has a countable subcover, with set of centres D_n; then $D = \bigcup_n D_n$ is countable and meets every ball $B(x, 2/n)$, as x lies in some $B(y, 1/n)$ with $y \in D_n$. So D is dense.

(2) If D is dense in X and $f : X \to Y$ is continuous and surjective, then $Y = f(\overline{D}) \subseteq \overline{f(D)}$ (Proposition 18.2.13(3)). If U is open, a nonempty open subset of U is open in X and meets D, so $D \cap U$ is dense in U. A subspace of a second countable space is second countable (intersect the basis with it), which with (1) gives the last statement. □

Products behave surprisingly well: a product of uncountably many separable spaces can still be separable, although it is then not even first countable (Example 18.12.4).

Theorem 18.8.15 (Hewitt–Marczewski–Pondiczery)**.** *A product of at most $2^{\aleph_0}$ separable spaces is separable.*

Proof. Let $X = \prod_{t \in T} X_t$ with each X_t separable. If some X_t is empty, so is X, and there is nothing to prove. Otherwise choose for each t a sequence $(d_t(n))_{n \geq 1}$ whose set of values is dense in X_t, and, as $|T| \leq 2^{\aleph_0} = |\mathbb{R}|$, regard T as a subset of $\mathbb{R}$. For pairwise disjoint intervals $I_1, \ldots, I_k$ with rational endpoints and integers $n_1, \ldots, n_k \geq 1$ let $x \in X$ be the point with

$$x_t = d_t(n_j) \quad \text{for } t \in T \cap I_j, \qquad x_t = d_t(1) \quad \text{for } t \notin I_1 \cup \cdots \cup I_k.$$

These points form a countable set D, by Corollary 3.6.13. Let $W = \prod_t U_t$ be a nonempty basic open set, with $U_t = X_t$ except for distinct $t_1, \dots, t_k$. Choose pairwise disjoint intervals $I_j \ni t_j$ with rational endpoints, and n_j with $d_{t_j}(n_j) \in U_{t_j}$. The corresponding point of D lies in W. So D is dense. □

Example 18.8.16. $\mathbb{R}^{\mathbb{R}}$, $[0,1]^{[0,1]}$ and $\{0,1\}^{\mathbb{R}}$ are separable. So, by Proposition 18.8.14(2), is every continuous image of them; on the other hand the compact space $\{0,1\}^{\mathbb{R}}$ is not metrisable, since a compact metric space is second countable (by Theorem 18.7.4 it is totally bounded, so finite $1/n$-nets give a countable dense set) while $\{0,1\}^{\mathbb{R}}$ is not even first countable, by the argument of Example 18.12.4.

The bound $2^{\aleph_0}$ is sharp.

Proposition 18.8.17. *If $\{0,1\}^T$, with $\{0,1\}$ discrete, is separable, then $|T| \le 2^{\aleph_0}$.*

Proof. Let D be a countable dense subset and send $t \in T$ to $D_t = \{d \in D : d_t = 1\}$. For $s \neq t$ the open set $\{x : x_s = 1, x_t = 0\}$ is nonempty, so it contains some $d \in D$, which lies in D_s and not in D_t. So $t \mapsto D_t$ is an injection $T \to \mathcal{P}(D)$, and $|T| \le 2^{|D|} \le 2^{\aleph_0}$. □

Exercise 18.8.18. Show that the Sorgenfrey line S is Lindelöf, but the Sorgenfrey plane $S \times S$ is not. (Together with Lemma 18.8.7 this gives a second proof that S is normal, and shows again that $S \times S$ is not metrisable.)

Solution. Let $\mathcal{U}$ be an open cover of S; replacing each member by the half-open intervals it contains, we may assume that it consists of half-open intervals $[a,b)$ (a countable subcover of the new cover gives one of the old). Let W be the union of the open intervals (a,b) with $[a,b) \in \mathcal{U}$. As a subspace of the Euclidean line, W is second countable, hence Lindelöf (Propositions 18.3.12 and 18.8.14(2)), so countably many of the intervals (a,b) cover W. Every point $x \in S \setminus W$ is the left endpoint of some $[x, b_x) \in \mathcal{U}$, and $(x, b_x) \subseteq W$. For $x < y$ in $S \setminus W$ the intervals (x, b_x) and (y, b_y) are disjoint, since otherwise $y \in (x, b_x) \subseteq W$. Disjoint nonempty open intervals contain distinct rationals, so $S \setminus W$ is countable, and countably many further members of $\mathcal{U}$ cover it.

In $S \times S$, the open cover consisting of $(S \times S) \setminus L$ and the sets $[x, x+1) \times [-x, -x+1)$, $x \in \mathbb{R}$, has no countable subcover, since each of these sets meets the uncountable antidiagonal L of Example 18.8.13 in at most one point. A metrisable space is normal; for the non-metrisability of $S \times S$ one can also use that it is separable but not Lindelöf, which contradicts Proposition 18.8.14(1). □

18.9 Local compactness and proper maps

Definition 18.9.1. A space is *locally compact* if every point has a compact neighbourhood. A continuous map $f : X \to Y$ is *proper* if $f^{-1}(K)$ is compact for every compact $K \subseteq Y$. The *support* of a function $f : X \to \mathbb{K}$ is $\operatorname{supp} f = \overline{\{f \neq 0\}}$, and $C_c(X)$ denotes the continuous functions with compact support.

Definition 18.9.2. Let X be a Hausdorff space. The *one-point compactification* is $X^+ = X \sqcup \{\infty\}$, whose open sets are the open subsets of X and the sets $(X \setminus K) \cup \{\infty\}$ with $K \subseteq X$ compact.

Theorem 18.9.3. *Let X be Hausdorff. Then X^+ is a compact space containing X as an open subspace, and X^+ is Hausdorff if and only if X is locally compact.*

Proof. Compact subsets of X are closed (Proposition 18.6.3), so the sets $X \setminus K$ are open. The open sets form a topology: $\bigcup_i((X \setminus K_i) \cup \{\infty\}) = (X \setminus \bigcap_i K_i) \cup \{\infty\}$ and $U \cup (X \setminus K) \cup \{\infty\} = (X \setminus (K \setminus U)) \cup \{\infty\}$, where $\bigcap_i K_i$ and $K \setminus U$ are closed subsets of a compact set, hence compact; and $U \cap ((X \setminus K) \cup \{\infty\}) = U \cap (X \setminus K)$ and $((X \setminus K) \cup \{\infty\}) \cap ((X \setminus L) \cup \{\infty\}) = (X \setminus (K \cup L)) \cup \{\infty\}$. The traces on X of the open sets are open in X, so X is an open subspace. Given an open cover of X^+, a member $(X \setminus K) \cup \{\infty\}$ contains ∞, and finitely many members cover K.

If X is locally compact, points of X are separated in X, and $x \in X$ with a compact neighbourhood K is separated from ∞ by $\operatorname{int} K$ and $(X \setminus K) \cup \{\infty\}$. Conversely, if x and ∞ have disjoint neighbourhoods U and $(X \setminus K) \cup \{\infty\}$, then $U \subseteq K$, so K is a compact neighbourhood of x. □

Example 18.9.4. $(\mathbb{R}^n)^+ \cong S^n$. Let $N = (0, \dots, 0, 1)$ and define $\tau\colon \mathbb{R}^n \to S^n$ by $\tau(y) = (2y, \|y\|^2 - 1)/(\|y\|^2 + 1)$. A direct computation shows $\|\tau(y)\| = 1$, that τ is a bijection onto $S^n \setminus \{N\}$ with inverse the *stereographic projection* $x \mapsto (x_1, \dots, x_n)/(1 - x_{n+1})$, and that $\|\tau(y) - N\| = 2/\sqrt{\|y\|^2 + 1}$. Extend τ by $\tau(\infty) = N$. It is continuous at ∞: for $\varepsilon > 0$, τ maps the complement of a closed ball of large radius R, which is a compact set, into $B(N, \varepsilon)$. So $\tau\colon (\mathbb{R}^n)^+ \to S^n$ is a continuous bijection from a compact space to a Hausdorff space, hence a homeomorphism.

Lemma 18.9.5. *Let X be locally compact Hausdorff, $K \subseteq X$ compact and $U \supseteq K$ open. There is an open V with compact closure such that $K \subseteq V \subseteq \overline{V} \subseteq U$, and there is $f \in C_c(X)$ with values in $[0, 1]$, $f = 1$ on K and* $\operatorname{supp} f \subseteq U$.

Proof. By Theorem 18.9.3 and Proposition 18.8.3, X^+ is normal. The set K is closed in X^+, $X^+ \setminus U$ is closed, and they are disjoint. By Lemma 18.8.2 there is an open V with $K \subseteq V$ and $\overline{V} \subseteq U$ (closure in X^+); then $\overline{V}$ is a closed subset of X^+ not containing ∞, so it is compact and equals the closure of V in X. Urysohn's lemma (Theorem 18.8.4) in X^+ gives a continuous $f\colon X^+ \to [0, 1]$ equal to 1 on K and 0 on $X^+ \setminus V$. Its restriction to X has support contained in the compact set $\overline{V} \subseteq U$, so the support is compact. □

Proposition 18.9.6. *Let $f\colon X \to Y$ be a continuous map to a locally compact Hausdorff space. If f is proper, then f is closed. A continuous map from a compact space to a Hausdorff space is proper.*

Proof. Let $C \subseteq X$ be closed and $y \in \overline{f(C)}$. Choose a compact neighbourhood K of y. Then $C \cap f^{-1}(K)$ is compact, so $f(C \cap f^{-1}(K)) = f(C) \cap K$ is compact, hence closed. Every open $W \ni y$ gives an open set $W \cap \operatorname{int} K \ni y$, which meets $f(C)$; so $y \in \overline{f(C) \cap K} = f(C) \cap K$. For the last statement, compact subsets of a Hausdorff space are closed, and closed subsets of compact spaces are compact. □

Counterexample 18.9.7. $\mathbb{Q}$ is not locally compact. A compact neighbourhood K of 0 in $\mathbb{Q}$ would contain $[-\varepsilon, \varepsilon] \cap \mathbb{Q}$ for some $\varepsilon > 0$, which is closed in K and hence compact. But choosing an irrational $\alpha \in (0, \varepsilon)$, the open sets $(\mathbb{Q} \cap (-\infty, \alpha - 1/n)) \cup (\mathbb{Q} \cap (\alpha + 1/n, \infty))$, $n \geq 1$, form an increasing family that covers $[-\varepsilon, \varepsilon] \cap \mathbb{Q}$ without finite subcover.

18.10 Paracompactness and partitions of unity

Definition 18.10.1. A family $(A_i)_{i \in I}$ of subsets of X is *locally finite* if every point has a neighbourhood meeting A_i for only finitely many i. A *refinement* of a cover (U_i) is a cover (V_j) such that each V_j is contained in some U_i. A space is *paracompact* if every open cover has a locally finite open refinement.

Lemma 18.10.2. *If (A_i) is locally finite, then so is $(\overline{A_i})$, and $\overline{\bigcup_i A_i} = \bigcup_i \overline{A_i}$. In particular a union of a locally finite family of closed sets is closed. If (f_i) are continuous functions $X \to \mathbb{K}$ whose supports form a locally finite family, then $\sum_i f_i$ is a well-defined continuous function.*

Proof. An open set meets $\overline{A_i}$ if and only if it meets A_i. Let $x \in \overline{\bigcup_i A_i}$ and let W be an open neighbourhood of x meeting only $A_{i_1}, \dots, A_{i_k}$. Every open $W' \ni x$ satisfies $W' \cap W \cap \bigcup_i A_i \neq \emptyset$, so W' meets $A_{i_1} \cup \cdots \cup A_{i_k}$; hence $x \in \overline{A_{i_1} \cup \cdots \cup A_{i_k}} = \overline{A_{i_1}} \cup \cdots \cup \overline{A_{i_k}}$ by Lemma 18.2.4. For the sum, each point has an open neighbourhood on which all but finitely many f_i vanish, and on it the sum is a finite sum of continuous functions (Proposition 18.4.7(5)); conclude by the pasting lemma. □

Proposition 18.10.3. *A paracompact Hausdorff space is normal.*

Proof. Regularity. Let C be closed and $x \notin C$. For $c \in C$ choose disjoint open $U_c \ni c$ and $W_c \ni x$. Let $\mathcal{V}$ be a locally finite open refinement of the cover $\{U_c\} \cup \{X \setminus C\}$, and $\mathcal{V}'$ the members meeting C; each is contained in some U_c, so its closure is contained in $X \setminus W_c$ and does not contain x. Then $V = \bigcup \mathcal{V}'$ is an open set containing C with $\overline{V} = \bigcup_{V' \in \mathcal{V}'} \overline{V'} \not\ni x$ by Lemma 18.10.2. So V and $X \setminus \overline{V}$ separate C and x.

Normality. The same argument, with x replaced by a closed set D disjoint from C and the sets U_c, W_c provided by regularity, separates C and D. □

Lemma 18.10.4 (Shrinking lemma)**.** *Let X be normal and $(U_i)_{i \in I}$ an open cover that is* point-finite *(each point lies in finitely many U_i), for instance locally finite. There is an open cover $(V_i)_{i \in I}$ with $\overline{V_i} \subseteq U_i$ for all i.*

Proof. Consider pairs $(J, (V_j)_{j \in J})$ with $J \subseteq I$, V_j open and $\overline{V_j} \subseteq U_j$, such that $(V_j)_{j \in J} \cup (U_i)_{i \notin J}$ covers X, ordered by extension. The pair $(\emptyset, ())$ is one. Given a chain, let J^* be the union of the index sets, with the V_j defined compatibly. Let $x \in X$ and F the finite nonempty set of i with $x \in U_i$. If $F \not\subseteq J^*$, x is covered by some U_i with $i \notin J^*$. Otherwise $F \subseteq J$ for some member (J, V) of the chain; there x is covered by some V_j, $j \in J$, since $x \in U_i$ implies $i \in F \subseteq J$. So the union is an upper bound, and Zorn's lemma gives a maximal pair (J, V). If $i \notin J$, the set $C = X \setminus (\bigcup_{j \in J} V_j \cup \bigcup_{k \notin J, k \neq i} U_k)$ is closed and contained in U_i; by Lemma 18.8.2 choose open V_i with $C \subseteq V_i \subseteq \overline{V_i} \subseteq U_i$, contradicting maximality. So $J = I$. □

Definition 18.10.5. A *partition of unity* on X is a family of continuous functions $\psi_i \colon X \to [0,1]$ whose supports form a locally finite family and with $\sum_i \psi_i = 1$. It is *subordinate* to an open cover $(U_i)_{i \in I}$ (with the same index set) if $\operatorname{supp} \psi_i \subseteq U_i$ for all i.

Theorem 18.10.6. *Let X be paracompact Hausdorff. Every open cover $(U_i)_{i \in I}$ has a subordinate partition of unity.*

Proof. Let $(W_k)_{k \in K}$ be a locally finite open refinement, with $W_k \subseteq U_{\varphi(k)}$ for a chosen map $\varphi \colon K \to I$. The space is normal (Proposition 18.10.3), so by Lemma 18.10.4 there is an open cover (V_k) with $\overline{V_k} \subseteq W_k$, and by Lemma 18.8.2 open V_k' with $\overline{V_k} \subseteq V_k' \subseteq \overline{V_k'} \subseteq W_k$. By Urysohn's lemma choose $f_k \colon X \to [0,1]$ equal to 1 on $\overline{V_k}$ and 0 outside V_k', so $\operatorname{supp} f_k \subseteq \overline{V_k'} \subseteq W_k$. By Lemma 18.10.2, $f = \sum_k f_k$ is continuous, and $f \geq 1$ because the V_k cover. The functions $g_k = f_k / f$ are continuous with supports in W_k and sum 1. Finally let $\psi_i = \sum_{\varphi(k) = i} g_k$. Its support is contained in $\bigcup_{\varphi(k)=i} \overline{V_k'}$, which is closed by Lemma 18.10.2 and contained in U_i; the supports of the ψ_i are locally finite because each point has a neighbourhood meeting only finitely many W_k; and $\sum_i \psi_i = \sum_k g_k = 1$. □

Proposition 18.10.7. *Let X be locally compact Hausdorff and second countable. There are compact sets $K_1 \subseteq K_2 \subseteq \cdots$ with $K_n \subseteq \operatorname{int} K_{n+1}$ and $\bigcup_n K_n = X$ (an* exhaustion by compact sets*), and X is paracompact.*

Proof. Let $\mathcal{B}$ be a countable basis, and $\mathcal{B}'$ the members with compact closure. $\mathcal{B}'$ covers X: if x has a compact neighbourhood K and $x \in B \subseteq \operatorname{int} K$ with $B \in \mathcal{B}$, then $\overline{B} \subseteq K$ is compact. Enumerate $\mathcal{B}' = \{B_1, B_2, \ldots\}$ (with repetitions if finite; if $X = \emptyset$ there is nothing to prove). Let $K_1 = \overline{B_1}$, and given K_n choose $m_n \geq n+1$ with $K_n \subseteq B_1 \cup \cdots \cup B_{m_n}$ and let $K_{n+1} = \overline{B_1} \cup \cdots \cup \overline{B_{m_n}}$. Then $K_n \subseteq \operatorname{int} K_{n+1}$ and $B_n \subseteq K_{n+1}$.

Put $K_0 = K_{-1} = \emptyset$ and let $\mathcal{U}$ be an open cover. For $n \geq 1$ the compact set $L_n = K_n \setminus \operatorname{int} K_{n-1}$ is contained in the open set $O_n = \operatorname{int} K_{n+1} \setminus K_{n-2}$. Cover L_n by finitely many sets $U \cap O_n$ with $U \in \mathcal{U}$, and let $\mathcal{V}$ be the collection of all these sets for all n. It is an open refinement of $\mathcal{U}$, and it covers X because a point lies in L_n for the least n with $x \in K_n$. A point x lies in $\operatorname{int} K_m$ for some m, and the sets of $\mathcal{V}$ coming from L_n lie in $X \setminus K_{n-2}$, so they meet $\operatorname{int} K_m$ only if $n \leq m+1$. Hence $\mathcal{V}$ is locally finite. □

Theorem 18.10.8 (Stone)**.** *Every metric space is paracompact.*

Proof. This is [Sto48]; we give the proof of [Rud69]. Let $(U_s)_{s \in S}$ be an open cover and well-order S (Theorem 3.7.2). For $n \geq 1$ define inductively $V_{s,n}$ as the union of the balls $B(x, 2^{-n})$ over all x such that: (i) s is the least index with $x \in U_s$; (ii) $x \notin V_{t,j}$ for all t and all $j < n$; (iii) $B(x, 3 \cdot 2^{-n}) \subseteq U_s$. Each $V_{s,n}$ is open and contained in U_s by (iii).

Cover. For $x \in X$ let s be least with $x \in U_s$ and n with $B(x, 3 \cdot 2^{-n}) \subseteq U_s$. Either $x \in V_{t,j}$ for some $j < n$, or x satisfies (i)–(iii) and $x \in V_{s,n}$.

Local finiteness. Let $x \in X$, let s be least such that $x \in V_{s,n}$ for some n, fix such n, and choose $j \geq 1$ with $B(x, 2^{-j}) \subseteq V_{s,n}$. We claim that $B(x, 2^{-n-j})$ meets only finitely many $V_{t,i}$. If $i \geq n+j$, a ball $B(y, 2^{-i})$ in $V_{t,i}$ has $y \notin V_{s,n}$ by (ii) (as $n < i$), so $d(x,y) \geq 2^{-j}$; since $2^{-i} + 2^{-n-j} \leq 2^{-j}$, it does not meet $B(x, 2^{-n-j})$. If $i < n+j$, then $B(x, 2^{-n-j})$ meets $V_{t,i}$ for at most one t: suppose it contains $p \in B(y, 2^{-i}) \subseteq V_{t,i}$ and $q \in B(z, 2^{-i}) \subseteq V_{t',i}$ with $t < t'$ and centres y, z as in the definition. By (iii) $B(y, 3 \cdot 2^{-i}) \subseteq U_t$, and by (i) $z \notin U_t$, so $d(y,z) \geq 3 \cdot 2^{-i}$. But $d(y,z) < 2^{-i} + 2 \cdot 2^{-n-j} + 2^{-i} \leq 3 \cdot 2^{-i}$, since $2^{-n-j} \leq 2^{-i-1}$. So only finitely many pairs (t,i) occur. □

Remark 18.10.9. Topological manifolds (Hausdorff, second countable and locally homeomorphic to $\mathbb{R}^n$) are locally compact, hence paracompact by Proposition 18.10.7, and admit partitions of unity; smooth partitions of unity are constructed in Chapter 33. Without second countability this fails: the long line is a Hausdorff space locally homeomorphic to $\mathbb{R}$ that is not paracompact [Eng89]. Paracompactness is also the natural hypothesis under which Čech cohomology computes sheaf cohomology (Chapter 26).

18.11 Function spaces

For spaces X and Y let $C(X,Y)$ be the set of continuous maps $X \to Y$. Many constructions treat such maps as points of a space: a homotopy is a path of maps, the loops in a space form a space, a sequence of functions converges to a function. Which topology should $C(X,Y)$ carry? Two requirements are natural.

- *Evaluation should be continuous*: if f is close to g and x is close to y, then $f(x)$ should be close to $g(y)$.
- *Currying*: a continuous map $F \colon Z \times X \to Y$ of two variables is the same as a family of maps $F(z,-) \colon X \to Y$ depending on the parameter z, and this family should be a continuous map $Z \to C(X,Y)$, and conversely.

The product topology of Y^X (the topology of pointwise convergence) is too coarse for this, and the topology of uniform convergence needs a metric on Y. The right topology is the compact-open topology. We show that it satisfies both requirements when X is locally compact Hausdorff, that for metric Y it is the topology of uniform convergence on compact sets, and we characterise its compact subsets for compact X (the Arzelà–Ascoli theorem).

Definition 18.11.1. For $K \subseteq X$ compact and $U \subseteq Y$ open let

$$V(K, U) = \{f \in C(X, Y) : f(K) \subseteq U\}.$$

The *compact-open topology* on $C(X, Y)$ is the topology generated by the sets $V(K, U)$, that is, the coarsest topology in which they are open (Definition 18.2.9). Unless stated otherwise, $C(X, Y)$ carries this topology.

So a basic open set is a finite intersection $V(K_1, U_1) \cap \cdots \cap V(K_m, U_m)$: it consists of the maps that send each of finitely many compact sets K_i into a prescribed open set U_i.

Example 18.11.2.

1. If X is discrete, its compact subsets are its finite subsets, every map is continuous, and $V(K, U) = \bigcap_{x \in K} V(\{x\}, U)$. The sets $V(\{x\}, U)$ are the subbasic open sets of the product topology, so $C(X, Y) = Y^X$ with the product topology. For $X = \{1, \ldots, n\}$ this is Y^n.

2. For any X, the sets $V(\{x\}, U)$ are among the subbasic open sets, so the compact-open topology is finer than the topology of pointwise convergence, the subspace topology of Y^X. In general it is strictly finer: see Example 18.11.5.

3. If X is a point, $C(X, Y) = Y$.

The first and most useful fact is that, for a metric target, the compact-open topology is a familiar topology of analysis.

Proposition 18.11.3. *Let (Y, d) be a metric space. For $f \in C(X, Y)$, $K \subseteq X$ compact and $\varepsilon > 0$ let*

$$B_K(f, \varepsilon) = \left\{ g \in C(X, Y) : \sup_{x \in K} d(f(x), g(x)) < \varepsilon \right\}.$$

These sets form a basis of the compact-open topology. In other words, the compact-open topology is the topology of uniform convergence on compact sets*: a sequence f_n converges to f if and only if $\sup_{x \in K} d(f_n(x), f(x)) \to 0$ for every compact $K \subseteq X$.*

Proof. Note first that $x \mapsto d(f(x), g(x))$ is continuous, so its supremum over a nonempty compact K is attained (Proposition 18.6.3(3)) and finite; for $K = \emptyset$ the supremum is taken to be 0, and $B_\emptyset(f, \varepsilon) = C(X, Y)$. We prove two things: every set $V(K, U)$ contains a set $B_K(f, \varepsilon)$ around each of its points, and every set $B_K(f, \varepsilon)$ contains a basic open set of the compact-open topology around each of its points. Together they show that both families generate the same topology and that the sets $B_K(f, \varepsilon)$ form a basis (the intersection of $B_K(f, \varepsilon)$ and $B_L(f', \varepsilon')$ contains, around each of its points g, the set $B_{K \cup L}(g, \delta)$ for small δ, by the triangle inequality).

(a) Let $f \in V(K, U)$ with $K \neq \emptyset$. If $U = Y$, then $V(K, U) = C(X, Y)$. Otherwise the function $x \mapsto d(f(x), Y \setminus U) = \inf_{y \notin U} d(f(x), y)$ is continuous (it is 1-Lipschitz in $f(x)$) and positive on K, since $f(x)$ lies in the open set U and so a ball around $f(x)$ misses $Y \setminus U$. Its minimum ε on K is positive. If $g \in B_K(f, \varepsilon)$ and $x \in K$, then $d(g(x), f(x)) < \varepsilon \leq d(f(x), Y \setminus U)$, so $g(x) \in U$. Hence $B_K(f, \varepsilon) \subseteq V(K, U)$.

(b) Let $g \in B_K(f, \varepsilon)$ and put $\eta = \varepsilon - \sup_{x \in K} d(f(x), g(x)) > 0$; then $B_K(g, \eta) \subseteq B_K(f, \varepsilon)$ by the triangle inequality, so it suffices to find a basic open set W with $g \in W \subseteq B_K(g, \eta)$. For $x \in K$ let $K_x = K \cap g^{-1}(\bar{B}(g(x), \eta/4))$, a closed subset of K, hence compact (Proposition 18.6.3(1)).

The sets $K \cap g^{-1}(B(g(x), \eta/4))$ are open in K and cover it, so finitely many of them, for points $x_1, \dots, x_m$, cover K; a fortiori $K = K_{x_1} \cup \cdots \cup K_{x_m}$. Let

$$W = V\big(K_{x_1}, B(g(x_1), \eta/2)\big) \cap \cdots \cap V\big(K_{x_m}, B(g(x_m), \eta/2)\big).$$

Then $g \in W$, since $g(K_{x_i}) \subseteq \bar{B}(g(x_i), \eta/4)$. If $h \in W$ and $y \in K$, choose i with $y \in K_{x_i}$; then $d(h(y), g(y)) \le d(h(y), g(x_i)) + d(g(x_i), g(y)) < \eta/2 + \eta/4$. So $\sup_{y \in K} d(h(y), g(y)) \le 3\eta/4 < \eta$, and $h \in B_K(g, \eta)$.

The statement about sequences follows: $f_n \to f$ if and only if every basic neighbourhood $B_K(f, \varepsilon)$ eventually contains f_n. □

Corollary 18.11.4. *If X is compact and (Y, d) is a metric space, the compact-open topology on $C(X, Y)$ is the topology of the* uniform metric $d_\infty(f, g) = \sup_{x \in X} d(f(x), g(x))$.

Proof. The supremum is finite, as in the proof of Proposition 18.11.3, and d_∞ is a metric. Its balls are the sets $B_X(f, \varepsilon)$, and $B_K(f, \varepsilon) \supseteq B_X(f, \varepsilon)$ for every compact $K \subseteq X$; so the sets $B_X(f, \varepsilon)$ alone form a basis of the topology of Proposition 18.11.3. □

Example 18.11.5. Let $f_n \in C([0,1], \mathbb{R})$ be the "moving tent": f_n is 0 outside $[0, 2/n]$, $f_n(1/n) = 1$, and f_n is linear on $[0, 1/n]$ and on $[1/n, 2/n]$. For every x, $f_n(x) = 0$ as soon as $2/n < x$, and $f_n(0) = 0$; so $f_n \to 0$ pointwise. But $d_\infty(f_n, 0) = 1$ for all n, so f_n does not converge to 0 in the compact-open topology. On the non-compact space $X = \mathbb{R}$, the functions g_n that are tents of height 1 over $[n, n+2]$ converge to 0 uniformly on compact sets, hence in the compact-open topology, although $\sup_{x \in \mathbb{R}} |g_n(x)| = 1$: for non-compact X the compact-open topology is coarser than the topology of uniform convergence on all of X.

We now turn to the two requirements of the beginning. Both use local compactness.

Proposition 18.11.6. *Let X be locally compact Hausdorff and Y any space. The* evaluation map

$$\mathrm{ev} \colon C(X, Y) \times X \to Y, \qquad (f, x) \mapsto f(x),$$

is continuous. For arbitrary X, the evaluation $\mathrm{ev}_x \colon C(X, Y) \to Y$ at a fixed point x is continuous.

Proof. Let $(f, x) \in C(X, Y) \times X$ and let U be an open neighbourhood of $f(x)$. The set $f^{-1}(U)$ is an open neighbourhood of x, so by Lemma 18.9.5 (with $K = \{x\}$) there is an open $W \ni x$ with compact closure $\overline{W} \subseteq f^{-1}(U)$. Then $V(\overline{W}, U) \times W$ is an open neighbourhood of (f, x), and for (g, y) in it, $g(y) \in g(\overline{W}) \subseteq U$. So ev is continuous at (f, x). For the second statement, $\mathrm{ev}_x^{-1}(U) = V(\{x\}, U)$ is open. □

Theorem 18.11.7 (Exponential law)**.** *Let X, Y, Z be spaces. For a map $F \colon Z \times X \to Y$ let $\hat{F} \colon Z \to Y^X$ be $\hat{F}(z) = F(z, -)$.*

1. *If F is continuous, then $\hat{F}(z) \in C(X, Y)$ for every z, and $\hat{F} \colon Z \to C(X, Y)$ is continuous.*
2. *If X is locally compact Hausdorff, then conversely, for every continuous $G \colon Z \to C(X, Y)$ the map $Z \times X \to Y$, $(z, x) \mapsto G(z)(x)$, is continuous.*

Hence, for X locally compact Hausdorff, $F \mapsto \hat{F}$ is a bijection $C(Z \times X, Y) \to C(Z, C(X, Y))$.

Proof. (1) $\hat{F}(z)$ is the composite of the continuous maps $x \mapsto (z, x)$ and F. To show that $\hat{F}$ is continuous it suffices to show that the preimages of the subbasic sets $V(K, U)$ are open (Proposition 18.2.13). Let $z \in \hat{F}^{-1}(V(K, U))$, that is, $F(\{z\} \times K) \subseteq U$. The open set $F^{-1}(U) \subseteq Z \times X$ contains $\{z\} \times K$. For each $x \in K$ choose a basic open set $A_x \times B_x \subseteq F^{-1}(U)$ containing (z, x); finitely many $B_{x_1}, \dots, B_{x_m}$ cover K, and $A = A_{x_1} \cap \cdots \cap A_{x_m}$ is an open neighbourhood

of z with $A \times K \subseteq F^{-1}(U)$ (this is the tube lemma of the proof of Proposition 18.6.4). So $\hat{F}(A) \subseteq V(K,U)$, and $\hat{F}^{-1}(V(K,U))$ is open.

(2) The map is the composite of $G \times \mathrm{id}_X \colon Z \times X \to C(X,Y) \times X$ and the evaluation map, which is continuous by Proposition 18.11.6.

The last statement: $F \mapsto \hat{F}$ is injective, since $F(z,x) = \hat{F}(z)(x)$, and by (2) every continuous G is $\hat{F}$ for the continuous map $F(z,x) = G(z)(x)$. □

The name comes from writing Y^X for $C(X,Y)$: the theorem says $Y^{Z\times X} = (Y^X)^Z$, as for exponentials of numbers or of sets (where $Y^{Z\times X}$ and $(Y^X)^Z$ are in bijection for all sets). In the language of Chapter 6, for X locally compact Hausdorff the functor $- \times X$ on topological spaces is left adjoint to $C(X,-)$.

Example 18.11.8.

1. *Homotopies as paths.* A homotopy $H \colon X \times [0,1] \to Y$ is the same as a continuous map $X \to C([0,1],Y)$, for every space X, since $[0,1]$ is compact Hausdorff (apply the theorem with $Z = X$ and the roles of the factors exchanged). And if X is locally compact Hausdorff, a homotopy is also the same as a path $[0,1] \to C(X,Y)$, $t \mapsto H(-,t)$; so homotopy classes of maps $X \to Y$ are the path components of $C(X,Y)$. This is the starting point of the homotopy theory of Chapter 19, where the space $C([0,1],Y)$ of paths and its subspace of loops at a point play a central role.

2. *Continuity of composition.* For any space X and a locally compact Hausdorff space Y, composition $C(Y,W) \times C(X,Y) \to C(X,W)$ is continuous (Exercise 18.11.14). Without local compactness this can fail, which is one reason why algebraic topology often restricts to locally compact spaces or modifies the topology of $C(X,Y)$.

We come to the compact subsets of $C(X,Y)$. Bounded sequences of real numbers have convergent subsequences, but bounded sequences of continuous functions need not: on $[0,1]$ the functions x^n take values in $[0,1]$, but converge pointwise to a function that is 0 on $[0,1)$ and 1 at 1, which is not continuous, so no subsequence converges uniformly (Proposition 18.3.10). What goes wrong is that the graphs become steeper and steeper near 1. The following notion forbids this.

Definition 18.11.9. Let X be a space and (Y,d) a metric space. A family $\mathcal{F} \subseteq C(X,Y)$ is *equicontinuous at* $x \in X$ if for every $\varepsilon > 0$ there is a neighbourhood W of x such that $d(f(x'), f(x)) < \varepsilon$ for all $x' \in W$ and *all* $f \in \mathcal{F}$. It is *equicontinuous* if it is equicontinuous at every point.

Continuity of each f gives a neighbourhood W depending on f; equicontinuity asks for one neighbourhood that works for all members of the family. For example, a family of maps between metric spaces that are Lipschitz with a common constant L is equicontinuous (take $W = B(x, \varepsilon/L)$), while the family $\{x^n : n \in \mathbb{N}\}$ on $[0,1]$ is not equicontinuous at 1: for every $\delta > 0$, $1 - (1-\delta/2)^n > 1/2$ for large n.

Lemma 18.11.10. *Let X be a space, (Y,d) a metric space and $\mathcal{F} \subseteq C(X,Y)$ equicontinuous.*

1. *The closure $\overline{\mathcal{F}}$ of $\mathcal{F}$ in Y^X, with the product topology, consists of continuous maps and is equicontinuous.*

2. *If X is compact, the topology of pointwise convergence and the uniform topology coincide on $\mathcal{F}$.*

Proof. (1) Let $x \in X$ and $\varepsilon > 0$, and let W be a neighbourhood of x with $d(f(x'), f(x)) < \varepsilon/3$ for $x' \in W$ and $f \in \mathcal{F}$. Let $g \in \overline{\mathcal{F}}$ and $x' \in W$. The set of $h \in Y^X$ with $d(h(x), g(x)) < \varepsilon/3$

and $d(h(x'), g(x')) < \varepsilon/3$ is open in the product topology and contains g, so it contains some $f \in \mathcal{F}$. Then

$$d(g(x'), g(x)) \le d(g(x'), f(x')) + d(f(x'), f(x)) + d(f(x), g(x)) < \varepsilon.$$

So $\overline{\mathcal{F}}$ is equicontinuous at x with the same W; in particular each $g \in \overline{\mathcal{F}}$ is continuous.

(2) The uniform topology is the compact-open one (Corollary 18.11.4), which is finer than the pointwise one (Example 18.11.2(2)). Conversely, let $g \in \mathcal{F}$ and $\varepsilon > 0$. For each $x \in X$ choose an open $W_x \ni x$ with $d(h(x'), h(x)) < \varepsilon/4$ for all $x' \in W_x$ and $h \in \mathcal{F}$. Finitely many $W_{x_1}, \dots, W_{x_m}$ cover X. If $h \in \mathcal{F}$ satisfies $d(h(x_i), g(x_i)) < \varepsilon/4$ for $i = 1, \dots, m$, a condition defining a neighbourhood of g in the pointwise topology, then for $x \in W_{x_i}$,

$$d(h(x), g(x)) \le d(h(x), h(x_i)) + d(h(x_i), g(x_i)) + d(g(x_i), g(x)) < 3\varepsilon/4,$$

so $d_\infty(h, g) \le 3\varepsilon/4 < \varepsilon$. Hence every uniform ball around g contains, within $\mathcal{F}$, a pointwise neighbourhood of g. □

Theorem 18.11.11 (Arzelà–Ascoli)**.** *Let X be a compact space and (Y, d) a metric space. A subset $\mathcal{F} \subseteq C(X, Y)$ has compact closure in $C(X, Y)$, with the uniform metric, if and only if*

1. *$\mathcal{F}$ is equicontinuous, and*
2. *for every $x \in X$ the set $\mathcal{F}(x) = \{f(x) : f \in \mathcal{F}\}$ has compact closure in Y.*

Proof. Suppose (1) and (2). Let $\mathcal{G}$ be the closure of $\mathcal{F}$ in Y^X with the product topology. It is contained in the closed set $\prod_{x \in X} \overline{\mathcal{F}(x)}$, which is compact by (2) and Tychonoff's theorem (Theorem 18.6.8); so $\mathcal{G}$, a closed subset of a compact space, is compact in the pointwise topology. By Lemma 18.11.10(1), $\mathcal{G} \subseteq C(X, Y)$ and $\mathcal{G}$ is equicontinuous, so by Lemma 18.11.10(2), applied to $\mathcal{G}$, it is compact also in the uniform topology. A compact subset of the metric space $(C(X, Y), d_\infty)$ is closed (Proposition 18.6.3(2)); so the closure of $\mathcal{F}$ in the uniform topology is contained in $\mathcal{G}$, and it is compact, being a closed subset of a compact space.

Conversely, suppose that the closure $\overline{\mathcal{F}}$ of $\mathcal{F}$ in $(C(X, Y), d_\infty)$ is compact. The evaluation ev_x is continuous (Proposition 18.11.6), so $\mathrm{ev}_x(\overline{\mathcal{F}})$ is a compact subset of Y containing $\mathcal{F}(x)$; it is closed, so it contains $\overline{\mathcal{F}(x)}$, which is therefore compact: this is (2). For (1), let $x \in X$ and $\varepsilon > 0$. The compact metric space $\overline{\mathcal{F}}$ is totally bounded (Theorem 18.7.4), so there are $f_1, \dots, f_m \in \overline{\mathcal{F}}$ such that every $f \in \mathcal{F}$ has $d_\infty(f, f_i) < \varepsilon/3$ for some i. Let W be a neighbourhood of x with $d(f_i(x'), f_i(x)) < \varepsilon/3$ for $x' \in W$ and $i = 1, \dots, m$. For $f \in \mathcal{F}$ and $x' \in W$, choosing i as above, $d(f(x'), f(x)) \le d(f(x'), f_i(x')) + d(f_i(x'), f_i(x)) + d(f_i(x), f(x)) < \varepsilon$. □

For $Y = \mathbb{R}^m$, condition (2) says that $\mathcal{F}$ is pointwise bounded, by the Heine–Borel theorem (Theorem 18.6.5); this is the classical form of the theorem, proved again by a different method in Chapter 27, where it is used for differential equations and in complex analysis. Since $(C(X, Y), d_\infty)$ is a metric space, compact closure means that every sequence in $\mathcal{F}$ has a uniformly convergent subsequence (Theorem 18.7.4).

Example 18.11.12.

1. Let X and Y be compact metric spaces and $L > 0$. The set of maps $X \to Y$ that are Lipschitz with constant L is compact in $C(X, Y)$: it is equicontinuous, condition (2) holds because Y is compact, and it is closed, since a uniform (even pointwise) limit of L-Lipschitz maps is L-Lipschitz.
2. The family $\{\sin(nx) : n \in \mathbb{N}\}$ in $C([0, \pi], \mathbb{R})$ is bounded but has no uniformly convergent subsequence. Indeed it is not equicontinuous at 0: $\sin(n \cdot \pi/(2n)) = 1$ while $\sin(0) = 0$, and $\pi/(2n) \to 0$. Here the theorem is used in the direction "compact closure implies equicontinuous".

Exercise 18.11.13. Show that if Y is Hausdorff, then so is $C(X,Y)$ with the compact-open topology.

Solution. Let $f \neq g$, and choose x with $f(x) \neq g(x)$ and disjoint open sets $U \ni f(x)$ and $U' \ni g(x)$. Then $V(\{x\}, U)$ and $V(\{x\}, U')$ are disjoint open neighbourhoods of f and g: a map in both would send x into $U \cap U' = \emptyset$. □

Exercise 18.11.14. Let X be any space and Y a locally compact Hausdorff space. Show that composition $C(Y,W) \times C(X,Y) \to C(X,W)$, $(g,f) \mapsto g \circ f$, is continuous.

Solution. Let $g \circ f \in V(K,U)$, with $K \subseteq X$ compact and $U \subseteq W$ open. Then $f(K)$ is compact and contained in the open set $g^{-1}(U)$. By Lemma 18.9.5 there is an open A with compact closure such that $f(K) \subseteq A \subseteq \overline{A} \subseteq g^{-1}(U)$. Then $V(\overline{A}, U) \times V(K,A)$ is an open neighbourhood of (g,f), and for (g',f') in it, $g'(f'(K)) \subseteq g'(A) \subseteq U$. So composition maps this neighbourhood into $V(K,U)$, and the preimages of subbasic open sets are open. □

18.12 Nets and filters

In metric spaces sequences describe everything: closures, continuity and compactness. In general spaces they do not (Counterexample 18.3.8). The reason is that a point may have no countable neighbourhood basis, so that no sequence can "approach" it through all its neighbourhoods. The remedy is to index by sets larger than $\mathbb{N}$, ordered only partially: what one needs of $\mathbb{N}$ is only that any two indices have a common later one.

Definition 18.12.1. A *directed set* is a nonempty set D with a relation $\leq$ that is reflexive and transitive and such that any two elements d_1, d_2 have an upper bound $d \geq d_1, d_2$. A *net* in a space X is a map $D \to X$, $d \mapsto x_d$, from a directed set. It *converges* to x, written $x_d \to x$, if for every open $U \ni x$ there is d_0 with $x_d \in U$ for all $d \geq d_0$ (the net is *eventually* in U). A point x is a *cluster point* of the net if for every open $U \ni x$ and every d_0 there is $d \geq d_0$ with $x_d \in U$ (the net is *frequently* in U).

Example 18.12.2.

1. A sequence is a net indexed by $\mathbb{N}$, and the definitions agree with the usual ones.

2. *The neighbourhood net.* For $x \in X$ the set $\mathcal{N}_x$ of open neighbourhoods of x, ordered by reverse inclusion ($U \leq V$ if $V \subseteq U$), is directed, an upper bound of U and V being $U \cap V$. If $x_U \in U$ is chosen for every U, then $x_U \to x$: for $U \ni x$ open and $V \geq U$, $x_V \in V \subseteq U$. This is the basic example; it approaches x through all neighbourhoods at once.

3. *Unordered sums.* Let $(a_i)_{i \in I}$ be real numbers indexed by any set. The finite subsets $F \subseteq I$, ordered by inclusion, form a directed set, and $s_F = \sum_{i \in F} a_i$ is a net. If all $a_i \geq 0$ and $s = \sup_F s_F < \infty$, then $s_F \to s$: given $\varepsilon > 0$ choose F_0 with $s_{F_0} > s - \varepsilon$; for $F \supseteq F_0$, $s - \varepsilon < s_F \leq s$. This is how sums $\sum_{i \in I}$ over uncountable index sets, for example in Hilbert spaces with uncountable orthonormal bases, are defined.

4. *Riemann sums.* The tagged partitions of $[a,b]$, ordered by refinement of the partitions, form a directed set (a common refinement of two partitions is obtained by taking the union of their division points), and Riemann sums of a function f form a net. The Riemann integral of Chapter 27 can be defined as the limit of this net.

Proposition 18.12.3. *Let X be a space.*

1. *A point x lies in $\overline{A}$ if and only if some net in A converges to x.*

2. *A map $f : X \to Y$ is continuous at x if and only if $f(x_d) \to f(x)$ for every net $x_d \to x$. So f is continuous if and only if it preserves convergence of nets.*

3. *X is Hausdorff if and only if every net in X has at most one limit.*

4. *A net in a product $\prod_i X_i$ converges to x if and only if $p_i(x_d) \to p_i(x)$ for every i.*

5. *If X is first countable, nets may be replaced by sequences in (1) and (2).*

Proof. (1) If $x_d \to x$ with $x_d \in A$, every open $U \ni x$ contains some x_d, so meets A, and $x \in \overline{A}$ by Lemma 18.2.4. Conversely, if $x \in \overline{A}$, every $U \in \mathcal{N}_x$ meets A; choosing $x_U \in U \cap A$ gives a net in A converging to x (Example 18.12.2(2)).

(2) Let f be continuous at x (Remark 18.3.6) and $x_d \to x$. For open $V \ni f(x)$ there is an open $U \ni x$ with $f(U) \subseteq V$, and x_d is eventually in U, so $f(x_d)$ is eventually in V. Conversely, if f is not continuous at x, there is an open $V \ni f(x)$ such that no $U \in \mathcal{N}_x$ has $f(U) \subseteq V$. Choose $x_U \in U$ with $f(x_U) \notin V$. Then $x_U \to x$, but $f(x_U)$ is never in V.

(3) Let X be Hausdorff and $x_d \to x$, $x_d \to y$ with $x \neq y$. For disjoint open $U \ni x$, $V \ni y$ there are d_1, d_2 with $x_d \in U$ for $d \geq d_1$ and $x_d \in V$ for $d \geq d_2$; an upper bound d of d_1, d_2 gives $x_d \in U \cap V = \emptyset$, a contradiction. Conversely, suppose $x \neq y$ have no disjoint neighbourhoods. The pairs $(U, V) \in \mathcal{N}_x \times \mathcal{N}_y$, ordered by reverse inclusion in both components, form a directed set; choose $x_{(U,V)} \in U \cap V$. This net converges to x and to y.

(4) The projections are continuous, so (2) gives one direction. Conversely, let $p_i(x_d) \to p_i(x)$ for all i, and let $W = \prod_i U_i$ be a basic open set containing x, with $U_i = X_i$ except for $i \in \{i_1, \ldots, i_k\}$ (Proposition 18.4.7(1)). There are $d_1, \ldots, d_k$ with $p_{i_j}(x_d) \in U_{i_j}$ for $d \geq d_j$; for d above an upper bound of $d_1, \ldots, d_k$, which exists by induction on k, $x_d \in W$. Every open set containing x contains such a W.

(5) Let $U_1, U_2, \ldots$ be open neighbourhoods of x such that every open set containing x contains one of them, and $V_n = U_1 \cap \cdots \cap U_n$. If $x_n \in V_n$ for all n, then $x_n \to x$, since $x_m \in V_m \subseteq V_n \subseteq U_n$ for $m \geq n$. In the proofs of (1) and (2), use the V_n in place of $\mathcal{N}_x$. □

By (4), convergence in a product is coordinatewise convergence; this is why the product topology on a space of functions $\prod_{s \in S} \mathbb{R} = \mathbb{R}^S$ is called the topology of *pointwise convergence*. The following example shows that sequences are not enough there.

Example 18.12.4. In $\mathbb{R}^{\mathbb{R}}$ with the product topology let A be the set of functions $f : \mathbb{R} \to \{0, 1\}$ with $f(s) = 1$ for all but finitely many s. The zero function lies in $\overline{A}$: a basic neighbourhood of 0 restricts the values at finitely many points $s_1, \ldots, s_k$, and contains the function that vanishes at these points and equals 1 elsewhere. A net in A converging to 0 is given by $f_F = \mathbf{1}_{\mathbb{R} \setminus F}$, indexed by the finite sets $F \subseteq \mathbb{R}$. But no sequence $f_n \in A$ converges to 0: the sets $\{f_n = 0\}$ are finite, so their union is countable, and at a point s outside it $f_n(s) = 1$ for all n, so $f_n(s) \not\to 0$. So $\mathbb{R}^{\mathbb{R}}$ is not first countable at 0, by Proposition 18.12.3(5).

For compactness one needs the analogue of subsequences. A subnet may run through the original net in a more complicated way than a subsequence, possibly repeating indices; what matters is only that it goes arbitrarily far out.

Definition 18.12.5. A *subnet* of a net $(x_d)_{d \in D}$ is a net $(x_{\varphi(e)})_{e \in E}$, where E is a directed set and $\varphi : E \to D$ is a map such that for every $d_0 \in D$ there is $e_0 \in E$ with $\varphi(e) \geq d_0$ for all $e \geq e_0$.

A subsequence (x_{n_k}), with $n_1 < n_2 < \cdots$, is a subnet, as $n_k \geq k$. If $x_d \to x$, every subnet converges to x: if $x_d \in U$ for $d \geq d_0$, then $x_{\varphi(e)} \in U$ for $e \geq e_0$.

Lemma 18.12.6. *A point x is a cluster point of a net $(x_d)_{d \in D}$ if and only if some subnet converges to x.*

Proof. Let $(x_{\varphi(e)})$ converge to x, let $U \ni x$ be open and $d_0 \in D$. There are e_0 with $\varphi(e) \geq d_0$ for $e \geq e_0$ and e_1 with $x_{\varphi(e)} \in U$ for $e \geq e_1$; for an upper bound e of e_0, e_1, $d = \varphi(e) \geq d_0$ and $x_d \in U$. So x is a cluster point.

Conversely, let x be a cluster point, and let E be the set of pairs (d, U) with $d \in D$, $U \in \mathcal{N}_x$ and $x_d \in U$, ordered by $(d, U) \leq (d', U')$ if $d \leq d'$ and $U' \subseteq U$. It is nonempty, as $(d, X) \in E$ for every d. It is directed: given (d_1, U_1) and (d_2, U_2), let d_0 be an upper bound of d_1, d_2; as x is a cluster point, there is $d \geq d_0$ with $x_d \in U_1 \cap U_2$, and $(d, U_1 \cap U_2)$ is an upper bound. Let $\varphi(d, U) = d$. Given d_0, every $(d, U) \geq (d_0, X)$ has $d \geq d_0$, so this is a subnet. It converges to x: for $U \in \mathcal{N}_x$ choose d with $x_d \in U$; then for $(d', U') \geq (d, U)$ we have $x_{d'} \in U' \subseteq U$. □

Theorem 18.12.7. *For a space X the following are equivalent:*

1. *X is compact;*
2. *every net in X has a cluster point;*
3. *every net in X has a convergent subnet.*

Proof. (2) and (3) are equivalent by Lemma 18.12.6.

(1)⇒(2): Suppose the net (x_d) has no cluster point. Then every $x \in X$ has an open $U_x \ni x$ and an index d_x with $x_d \notin U_x$ for all $d \geq d_x$. Finitely many $U_{x_1}, \ldots, U_{x_n}$ cover X. For an upper bound d of $d_{x_1}, \ldots, d_{x_n}$, the point x_d lies in none of the U_{x_j}, a contradiction.

(2)⇒(1): Suppose the open cover $\mathcal{U}$ has no finite subcover. The finite subfamilies $\mathcal{F} \subseteq \mathcal{U}$, ordered by inclusion, form a directed set, and we may choose $x_{\mathcal{F}} \notin \bigcup \mathcal{F}$. Any $x \in X$ lies in some $U \in \mathcal{U}$, and $x_{\mathcal{F}} \notin U$ for all $\mathcal{F} \supseteq \{U\}$; so x is not a cluster point. □

For metric spaces, compactness is equivalent to sequential compactness (Theorem 18.7.4); in general neither implies the other. Here is a compact space that is not sequentially compact.

Example 18.12.8. Let $S = \{0,1\}^{\mathbb{N}}$ be the set of 0-1 sequences, and $X = \{0,1\}^S$, a product of discrete two-point spaces, which is compact by Tychonoff's theorem (Theorem 18.6.8). Let $f_n \in X$ be the point $f_n(s) = s(n)$. Given $n_1 < n_2 < \cdots$, choose $s \in S$ with $s(n_k) = 0$ for even k and $s(n_k) = 1$ for odd k. Then $f_{n_k}(s)$ alternates between 1 and 0, so by Proposition 18.12.3(4) the subsequence (f_{n_k}) does not converge. So (f_n) has no convergent subsequence, although it has convergent subnets by Theorem 18.12.7.

Filters are a second, equivalent language, often more convenient because they need no index set. We use the definitions of Chapter 5: a *filter* on a set X is a family $\mathcal{F}$ of subsets with $X \in \mathcal{F}$, $\emptyset \notin \mathcal{F}$, closed under finite intersections and supersets, and an *ultrafilter* is a filter containing A or $X \setminus A$ for every $A \subseteq X$ (Definition 5.3.1). Every family of subsets with the finite intersection property lies in an ultrafilter (Lemma 5.3.2).

Definition 18.12.9. A filter $\mathcal{F}$ on a space X *converges* to x if every open set containing x belongs to $\mathcal{F}$. For a map $f : X \to Y$, the *image filter* is $f_*\mathcal{F} = \{B \subseteq Y : f^{-1}(B) \in \mathcal{F}\}$.

The *neighbourhood filter* of x, the sets containing an open neighbourhood of x, converges to x, and a filter converges to x if and only if it contains the neighbourhood filter. A net (x_d) defines the filter of sets B that contain a *tail* $\{x_d : d \geq d_0\}$, which converges to x exactly when the net does; so filters and nets describe the same convergence. The image filter is a filter ($f^{-1}(\emptyset) = \emptyset$ and preimages preserve intersections and inclusions), and if $\mathcal{F}$ is an ultrafilter, so is $f_*\mathcal{F}$, since $f^{-1}(Y \setminus B) = X \setminus f^{-1}(B)$. If f is continuous and $\mathcal{F} \to x$, then $f_*\mathcal{F} \to f(x)$: for open $V \ni f(x)$, $f^{-1}(V)$ is an open set containing x, so it lies in $\mathcal{F}$.

Theorem 18.12.10. *A space X is compact if and only if every ultrafilter on X converges.*

Proof. Let X be compact and $\mathcal{U}$ an ultrafilter without limit. Every x has an open $U_x \ni x$ with $U_x \notin \mathcal{U}$, so $X \setminus U_x \in \mathcal{U}$. Finitely many $U_{x_1}, \dots, U_{x_n}$ cover X, and then $\emptyset = \bigcap_j (X \setminus U_{x_j}) \in \mathcal{U}$, a contradiction.

Conversely, let C be an open cover without finite subcover. Then the complements $X \setminus U$, $U \in C$, have the finite intersection property, so they lie in an ultrafilter $\mathcal{U}$. If $\mathcal{U} \to x$ and $x \in U \in C$, then $U \in \mathcal{U}$ and $X \setminus U \in \mathcal{U}$, so $\emptyset \in \mathcal{U}$, a contradiction. □

With ultrafilters Tychonoff's theorem has a two-line proof, which shows clearly where the axiom of choice enters: in choosing the limits.

Corollary 18.12.11. *A product of compact spaces is compact.*

Proof. Let $\mathcal{U}$ be an ultrafilter on $X = \prod_i X_i$. Each $(p_i)_*\mathcal{U}$ is an ultrafilter on the compact space X_i, so by Theorem 18.12.10 we may choose a limit x_i of it, and let $x = (x_i)_i$. A basic open set containing x is $W = p_{i_1}^{-1}(U_1) \cap \dots \cap p_{i_k}^{-1}(U_k)$ with $U_j \ni x_{i_j}$ open; then $U_j \in (p_{i_j})_*\mathcal{U}$, that is, $p_{i_j}^{-1}(U_j) \in \mathcal{U}$, and so $W \in \mathcal{U}$. Hence every open set containing x is in $\mathcal{U}$, $\mathcal{U} \to x$, and X is compact by the theorem. □

Example 18.12.12. *Limits along an ultrafilter.* An ultrafilter on $\mathbb{N}$ is *free* if it is not principal; free ultrafilters exist, since the cofinite subsets of $\mathbb{N}$ have the finite intersection property, and an ultrafilter containing them contains no finite set, so is not principal. Let $\mathcal{U}$ be a free ultrafilter and (a_n) a bounded real sequence, $a\colon \mathbb{N} \to [-M, M]$. The ultrafilter $a_*\mathcal{U}$ on the compact Hausdorff space $[-M, M]$ has a unique limit (uniqueness as in Proposition 18.12.3(3)), written $\lim_{\mathcal{U}} a_n$: it is the number L such that $\{n : |a_n - L| < \varepsilon\} \in \mathcal{U}$ for every $\varepsilon > 0$. Every bounded sequence has such a limit, for instance $\lim_{\mathcal{U}} (-1)^n$ is 1 or -1 according as $\mathcal{U}$ contains the even or the odd numbers. The limit is linear and multiplicative, lies between $\liminf a_n$ and $\limsup a_n$, and equals $\lim a_n$ when this exists, since every set $\{n : |a_n - L| < \varepsilon\}$ is then cofinite. This is the device behind ultraproducts (Chapter 5). The limit is not shift invariant (for $(-1)^n$ and its shift it gives opposite values), but its value on the averages $\frac{1}{n}(a_1 + \dots + a_n)$ is, since the averages of (a_n) and of (a_{n+1}) differ by at most $2M/n$; this gives a *Banach limit*, a shift-invariant positive linear functional on bounded sequences extending lim.

Remark 18.12.13. Nets were introduced by Moore and Smith (1922) and filters by Cartan (1937); Bourbaki's *General Topology* is written in the language of filters. Sequences still suffice in first countable spaces (Proposition 18.12.3(5)), which include all metric spaces and manifolds, and they are what one uses there. The exotic compact spaces of Example 18.12.8 and of the next section show why nets or filters are unavoidable in general.

18.13 The Stone–Čech compactification

The one-point compactification adds as little as possible to a locally compact space. At the other extreme one can ask for a compactification to which *every* bounded continuous function extends: for $(0, 1]$, the function $\sin(1/x)$ has no continuous extension to $[0, 1]$, so $[0, 1]$ is not such a compactification, and one has to add many more points. The construction embeds the space in a large cube by all its functions to $[0, 1]$ and takes the closure. It works for exactly the spaces that have enough such functions.

The spaces in question are the completely regular ones (Definition 18.8.10). Normal spaces are completely regular, and so are subspaces and products of completely regular spaces (Proposition 18.8.11). Compact Hausdorff spaces are normal (Proposition 18.8.3), so every subspace of a compact Hausdorff space is completely regular, for instance every locally compact Hausdorff space $X \subseteq X^+$ (Theorem 18.9.3). The converse is the content of the next theorem.

Theorem 18.13.1. *Let X be completely regular, $\mathcal{F} = C(X, [0,1])$ the set of continuous maps $X \to [0,1]$, and $e\colon X \to [0,1]^{\mathcal{F}}$ the map $e(x) = (f(x))_{f\in\mathcal{F}}$. Then e is an embedding, that is, a homeomorphism onto its image. So the completely regular spaces are exactly the subspaces of compact Hausdorff spaces.*

Proof. The components $p_f \circ e = f$ are continuous, so e is continuous (Proposition 18.4.7(2)). It is injective: for $x \neq y$, the set $\{y\}$ is closed, and some f has $f(x) = 0 \neq 1 = f(y)$. Let $U \subseteq X$ be open and $x \in U$. Choose $f \in \mathcal{F}$ with $f(x) = 0$ and $f = 1$ on $X \setminus U$, and let $W = p_f^{-1}([0,1))$, open in the cube. Then $e(x) \in W$, and if $e(y) \in W$, then $f(y) < 1$, so $y \in U$. Hence $e(U)$ is the union of the sets $W \cap e(X)$ obtained in this way, so it is open in $e(X)$. The cube is compact by Tychonoff's theorem and Hausdorff by Proposition 18.4.7(3), and this proves the last statement. □

Definition 18.13.2. For X completely regular, the *Stone–Čech compactification* βX is the closure of $e(X)$ in $[0,1]^{\mathcal{F}}$. We identify X with $e(X)$, a dense subspace of βX.

As a closed subset of a compact Hausdorff space, βX is compact Hausdorff (Proposition 18.6.3(1) and Proposition 18.4.7(3)).

Theorem 18.13.3. *Let X be completely regular. Every continuous map $g\colon X \to K$ to a compact Hausdorff space extends uniquely to a continuous map $\beta g\colon \beta X \to K$, $\beta g \circ e = g$.*

Proof. Uniqueness. Let $h_1, h_2\colon \beta X \to K$ be continuous and agree on $e(X)$. If $h_1(z) \neq h_2(z)$, choose disjoint open $V_1 \ni h_1(z)$ and $V_2 \ni h_2(z)$; the open set $h_1^{-1}(V_1) \cap h_2^{-1}(V_2)$ contains z, so it meets the dense set $e(X)$ in a point where $h_1 = h_2$ takes values in $V_1 \cap V_2 = \emptyset$, a contradiction.

Existence for cubes. If $K = [0,1]$, then $g \in \mathcal{F}$, and $\beta g = p_g|_{\beta X}$ works. If $K = [0,1]^J$ for a set J, extend each component $p_j \circ g$ and combine the extensions, which is continuous by Proposition 18.4.7(2).

General K. A compact Hausdorff space is completely regular, so by Theorem 18.13.1 there is an embedding $e_K\colon K \to Q = [0,1]^J$, with $J = C(K, [0,1])$; its image is compact, hence closed in Q. Let $h\colon \beta X \to Q$ extend $e_K \circ g$. By continuity $h(\beta X) = h(\overline{e(X)}) \subseteq \overline{h(e(X))} = \overline{e_K(g(X))} \subseteq e_K(K)$ (Proposition 18.2.13(3)). So $\beta g = e_K^{-1} \circ h$ is defined, and it is continuous, as e_K is a homeomorphism onto its image. □

Corollary 18.13.4. *Let X be completely regular, Y a compact Hausdorff space and $j\colon X \to Y$ an embedding with dense image such that every continuous map from X to a compact Hausdorff space extends along j. Then there is a unique homeomorphism $\beta X \to Y$ that is the identity on X, that is, sends $e(x)$ to $j(x)$.*

Proof. Theorem 18.13.3 gives $\beta j\colon \beta X \to Y$ with $\beta j \circ e = j$, and the hypothesis gives $k\colon Y \to \beta X$ with $k \circ j = e$. Then $k \circ \beta j$ is the identity on the dense set $e(X)$, hence everywhere by the uniqueness argument in the proof of the theorem, and likewise $\beta j \circ k$ is the identity on $j(X)$, hence on Y. Uniqueness of the homeomorphism is the same argument. □

In categorical terms (Chapter 6), β is left adjoint to the inclusion of compact Hausdorff spaces into completely regular spaces. Taking K a compact interval, the theorem says that restriction is a bijection $C(\beta X, \mathbb{R}) \to C_b(X, \mathbb{R})$, the bounded continuous functions on X: every bounded continuous function extends uniquely.

Example 18.13.5.

1. If X is compact Hausdorff, $e(X)$ is compact, hence closed, and $\beta X = X$.
2. The function $s(x) = \sin(1/x)$ on $(0,1]$ extends to $\beta s\colon \beta(0,1] \to [-1,1]$ but not to $[0,1]$; so $\beta(0,1] \neq [0,1]$, and in fact $\beta(0,1] \setminus (0,1]$ has more than one point. The sequence

$a_n = 1/(\frac{\pi}{2} + 2\pi n)$ has a cluster point z in the compact space $\beta(0,1]$ (Theorem 18.12.7), and $z \notin (0,1]$: otherwise z would be a cluster point of (a_n) in the subspace $(0,1]$, which has none, as $a_n \to 0$. Since $s(a_n) = 1$ for all n, every neighbourhood of $\beta s(z)$ contains 1 by continuity, so $\beta s(z) = 1$. In the same way the points $b_n = 1/(\frac{3\pi}{2} + 2\pi n)$ give a point $z' \notin (0,1]$ with $\beta s(z') = -1$.

3. *$\beta\mathbb{N}$ is not sequentially compact.* Let $\mathbb{N}$ be discrete, which is metric and so completely regular. Given $n_1 < n_2 < \cdots$, let $g\colon \mathbb{N} \to [0,1]$ be 1 at n_k for odd k and 0 elsewhere. If $n_k \to z$ in $\beta\mathbb{N}$, then $g(n_k) = \beta g(n_k) \to \beta g(z)$, which is impossible, as $g(n_k)$ alternates between 1 and 0. So the sequence (n) in the compact space $\beta\mathbb{N}$ has no convergent subsequence.

Remark 18.13.6. The space $\beta\mathbb{N}$ is a basic object of set-theoretic topology. Its points correspond to the ultrafilters on $\mathbb{N}$, the points of $\mathbb{N}$ to the principal ones, and it has cardinality $2^{2^{\aleph_0}}$; no sequence of distinct points of $\beta\mathbb{N}$ converges [Eng89]. Under this correspondence the ultrafilter limits of Example 18.12.12 are the values at the point $\mathcal{U} \in \beta\mathbb{N}$ of the continuous extensions of bounded sequences. In functional analysis βX appears as the space of characters of the Banach algebra $C_b(X,\mathbb{C}) \cong C(\beta X,\mathbb{C})$, by Gelfand's theory of commutative Banach algebras.

18.14 The Cantor set and space-filling curves

The Cantor set is the basic example of a compact space that is as disconnected as possible, and, surprisingly, it maps onto every cube; from this one gets curves that fill a square. Throughout, $\Sigma = \{0,1\}^{\mathbb{N}_{>0}}$, the set of sequences $a = (a_1, a_2, \ldots)$ of zeros and ones, is the product of countably many discrete two-point spaces, compact by Tychonoff's theorem. A basis of its topology is formed by the *cylinders* $[w] = \{a : a_1 = w_1, \ldots, a_k = w_k\}$ for finite words $w = w_1 \cdots w_k$ in 0 and 1.

Definition 18.14.1. The *Cantor set* is $C = c(\Sigma) \subseteq [0,1]$, where $c(a) = \sum_{n\geq 1} 2a_n 3^{-n}$: the numbers with a ternary expansion using only the digits 0 and 2.

Proposition 18.14.2. *1. The map $c\colon \Sigma \to C$ is a homeomorphism, and C is compact.*

2. *For a word w of length k, $c([w])$ lies in the closed interval J_w of length 3^{-k} with left endpoint $\sum_{n\leq k} 2w_n 3^{-n}$; the intervals J_{w0} and J_{w1} are the left and right thirds of J_w, and $C = \bigcap_k \bigcup_{|w|=k} J_w$. The complement $[0,1] \setminus C$ is the union of the open middle thirds M_w of the intervals J_w, which are pairwise disjoint and have their endpoints $c(w0111\cdots)$ and $c(w1000\cdots)$ in C. So C is the classical middle-thirds Cantor set: from $[0,1]$ remove the open middle third, from each remaining interval its open middle third, and so on.*

3. *C is uncountable, has no isolated points and empty interior, and is* totally disconnected*: its only connected subsets are points and $\emptyset$.*

Proof. (1) If a, b agree in the first N coordinates, $|c(a) - c(b)| \leq \sum_{n>N} 2 \cdot 3^{-n} = 3^{-N}$; since the cylinders form a basis, c is continuous. If $a \neq b$ and n is the first index with $a_n \neq b_n$, say $a_n = 0$, $b_n = 1$, then $c(b) - c(a) \geq 2 \cdot 3^{-n} - \sum_{m>n} 2 \cdot 3^{-m} = 3^{-n} > 0$. So c is a continuous bijection from a compact space onto the Hausdorff space C, hence a homeomorphism (Proposition 18.6.3(4)), and C is compact.

(2) For $a \in [w]$, $c(a)$ is the left endpoint plus $\sum_{n>k} 2a_n 3^{-n} \in [0, 3^{-k}]$. The left endpoints of J_{w0} and J_{w1} are those of J_w plus 0 and $2 \cdot 3^{-k-1}$, and their lengths are 3^{-k-1}, which gives the thirds. So $C \subseteq \bigcap_k \bigcup_{|w|=k} J_w$. Conversely, the 2^k intervals J_w with $|w| = k$ are pairwise disjoint (by induction, as the two thirds are disjoint), so a point x of the intersection lies, for each

k, in exactly one $J_{w^{(k)}}$, and these words extend each other. Let a be the infinite word they define; then x and $c(a)$ both lie in $J_{w^{(k)}}$ for all k, so $|x - c(a)| \le 3^{-k}$ for all k, and $x = c(a) \in C$. If $x \in [0,1] \setminus C$, let k be the largest integer such that x lies in some J_w with $|w| = k$ (level 0 is $J_\emptyset = [0,1]$); then $x \in J_w \setminus (J_{w0} \cup J_{w1}) = M_w$. The set M_w lies in J_w and misses $J_{w0} \cup J_{w1}$, which contain all the deeper intervals inside J_w, so it is disjoint from every $M_{w'}$ with $w' \neq w$. Finally the right endpoint of J_{w0} is $\sum_{n \le k} 2w_n 3^{-n} + 3^{-k-1} = c(w0111\cdots)$, and the left endpoint of J_{w1} is $c(w1000\cdots)$.

(3) Σ is uncountable by Cantor's theorem (Theorem 3.6.3), as it is in bijection with the set of subsets of $\mathbb{N}_{>0}$. Changing the n-th coordinate of a for large n gives points $b \neq a$ arbitrarily close to a, so there are no isolated points. If $a \neq b$, say $a_n \neq b_n$, the cylinder $\{x : x_n = a_n\}$ (a union of finitely many basic cylinders) is open and closed, contains a and not b; so no connected subset contains both. Finally, a nonempty open subset of $[0,1]$ contains an interval with more than one point, which is connected (Theorem 18.5.3); so C has empty interior. □

So C is a nonempty compact metric space that is totally disconnected and has no isolated points. *Brouwer's theorem* says that these properties characterise it: every such space is homeomorphic to C [Kec95]. For instance $C \times C$ and $C^{\mathbb{N}}$ are homeomorphic to C; for these one can see it directly (Exercise 18.14.5).

Proposition 18.14.3. 1. *The map $\varphi\colon C \to [0,1]$, $\varphi(c(a)) = \sum_{n \ge 1} a_n 2^{-n}$, is a continuous surjection.*

2. *For every $m \ge 1$ there is a continuous surjection $C \to [0,1]^m$, and there is a continuous surjection $C \to [0,1]^{\mathbb{N}}$ onto the* Hilbert cube.

Proof. (1) $\varphi \circ c$ is continuous, as in the proof of (1) above with 2^{-N} in place of 3^{-N}, and c is a homeomorphism. Every $t \in [0,1]$ has a binary expansion: define $a_n = 1$ if $s_{n-1} + 2^{-n} \le t$ and $a_n = 0$ otherwise, where $s_n = \sum_{m \le n} a_m 2^{-m}$, $s_0 = 0$. By induction $0 \le t - s_n \le 2^{-n}$ (if $a_n = 0$ then $t - s_{n-1} < 2^{-n}$, and if $a_n = 1$ then $0 \le t - s_{n-1} - 2^{-n} \le 2^{-n}$), so $s_n \to t$ and $\varphi(c(a)) = t$.

(2) Choose a bijection $\mathbb{N}_{>0} \to \mathbb{N}_{>0} \times \mathbb{N}_{>0}$, $n \mapsto (i(n), j(n))$ (Corollary 3.6.13). The map $\Sigma \to \Sigma^{\mathbb{N}_{>0}}$ sending a to the sequence of sequences $(b^{(i)})_i$ with $b^{(i)}_j = a_n$ for $(i,j) = (i(n), j(n))$ is a bijection, and it is continuous in both directions, because each coordinate of the image is a coordinate of a and conversely. So $\Sigma \cong \Sigma^{\mathbb{N}_{>0}}$, and composing with c and with the product of copies of $\varphi \circ c$, which is continuous by Proposition 18.4.7(2) and surjective, gives a continuous surjection $C \to [0,1]^{\mathbb{N}}$. For $[0,1]^m$ use instead a bijection $\mathbb{N}_{>0} \to \{1,\dots,m\} \times \mathbb{N}_{>0}$, such as $m(j-1) + i \mapsto (i,j)$ for $1 \le i \le m$, $j \ge 1$. □

The map φ is not injective: $c(0111\cdots)$ and $c(1000\cdots)$, the two endpoints $\frac{1}{3}$ and $\frac{2}{3}$ of the first removed interval, both map to $\frac{1}{2}$. Extended to $[0,1]$ by constancy on the removed intervals, φ becomes the *Cantor function*, continuous, nondecreasing and constant on each removed interval, which reappears in measure theory as a continuous function with derivative 0 almost everywhere. The same idea of filling the gaps gives a curve through every point of a square.

Theorem 18.14.4 (Space-filling curves)**.** *For every $m \ge 1$ there is a continuous surjection $\gamma\colon [0,1] \to [0,1]^m$.*

Proof. Let $\psi\colon C \to [0,1]^m$ be a continuous surjection (Proposition 18.14.3). By Proposition 18.14.2(2), $[0,1] \setminus C$ is the union of the removed open intervals (u,v), which are pairwise disjoint and have endpoints $u, v \in C$. Define $\gamma = \psi$ on C and

$$\gamma((1-\lambda)u + \lambda v) = (1-\lambda)\psi(u) + \lambda\psi(v) \qquad (0 < \lambda < 1)$$

on each removed interval (u, v). The values lie in the convex set $[0,1]^m$, and γ is surjective since ψ is. On the closure $[u, v]$ of each removed interval γ is affine, hence continuous.

Let $t \in C$; we show that γ is continuous at t from the right (if $t < 1$); the left side is symmetric. If t is the left endpoint of a removed interval, γ is affine on it, and continuity from the right is clear. Otherwise every interval $(t, t+\eta)$ with $0 < \eta \le 1 - t$ meets C: if it did not, this connected set would lie in the union of the pairwise disjoint open removed intervals, hence in one of them, (u, v) (Lemma 18.5.2); then $u \le t$, and $t \in C$ is not in (u, v), so $t = u$, which we excluded. Let $\varepsilon > 0$. As C is compact, ψ is uniformly continuous (Corollary 18.7.5): there is $\delta > 0$ with $\|\psi(x) - \psi(y)\| < \varepsilon$ for $x, y \in C$, $|x - y| < \delta$. Choose $s \in C \cap (t, t + \min(\delta, 1 - t))$. Let $t < t' < s$. If $t' \in C$, then $\|\gamma(t') - \gamma(t)\| < \varepsilon$. Otherwise t' lies in a removed interval (u, v), and since $t, s \in C$, $t \le u < v \le s$; so $\psi(u)$ and $\psi(v)$ lie in the open ball of radius ε about $\psi(t)$, which is convex, and so does $\gamma(t')$, a convex combination of them. Hence $\|\gamma(t') - \gamma(t)\| < \varepsilon$ for $t < t' < s$. □

Peano found the first such curve in 1890, and Hilbert a simpler geometric one in 1891, as a limit of polygonal paths through a grid of 4^k squares; the construction above is Lebesgue's. The curve cannot be injective: a continuous bijection $[0,1] \to [0,1]^2$ would be a homeomorphism (Proposition 18.6.3(4)), but removing an interior point disconnects $[0,1]$, while the square minus a point is still path-connected, hence connected (Proposition 18.5.7(2)): two points can be joined by a segment, or by two segments through a third point if the segment between them passes through the removed point. So dimension is not preserved by continuous surjections, but it is preserved by homeomorphisms: $[0,1]^m \cong [0,1]^n$ only for $m = n$, by the invariance of dimension proved with homology (Chapter 21). Every compact metric space is a continuous image of C (the Alexandroff–Hausdorff theorem [Kec95]), which is one reason for the importance of the Cantor set.

Exercise 18.14.5. Show that $\Sigma \times \Sigma$ and $\Sigma^{\mathbb{N}_{>0}}$ are homeomorphic to Σ, so that $C \times C \cong C^{\mathbb{N}} \cong C$. Show also that C is homeomorphic to the set of $x \in [0,1]$ whose decimal expansion uses only the digits 3 and 7 (with a suitable meaning of "expansion").

Solution. The proof of Proposition 18.14.3(2) gives $\Sigma \cong \Sigma^{\mathbb{N}_{>0}}$, and with the bijection $\mathbb{N}_{>0} \to \{1,2\} \times \mathbb{N}_{>0}$, $2n-1 \mapsto (1,n)$, $2n \mapsto (2,n)$, it gives $\Sigma \cong \Sigma \times \Sigma$: a sequence is split into its odd and even terms. For the decimal set, let $d(a) = \sum_n (3 + 4a_n)10^{-n}$. As in the proof of Proposition 18.14.2(1), d is continuous, and it is injective: if n is the first index with $a_n = 0$, $b_n = 1$, then $d(b) - d(a) \ge 4 \cdot 10^{-n} - \sum_{m>n} 4 \cdot 10^{-m} = 4 \cdot 10^{-n}(1 - \frac{1}{9}) > 0$. So d is a homeomorphism from Σ onto its image, which is the set of numbers $\sum_n d_n 10^{-n}$ with $d_n \in \{3,7\}$, and $c \circ d^{-1}$ is a homeomorphism of it with C. □

18.15 Exercises

Exercise 18.15.1. Show that X is Hausdorff if and only if the diagonal $\Delta = \{(x,x)\}$ is closed in $X \times X$. Deduce that if $f, g \colon Z \to X$ are continuous and X is Hausdorff, then $\{z : f(z) = g(z)\}$ is closed, and that the graph of a continuous map to a Hausdorff space is closed.

Solution. $(x,y) \notin \Delta$ has a basic neighbourhood $U \times V$ disjoint from Δ if and only if $U \cap V = \emptyset$. So $X \times X \setminus \Delta$ is open if and only if distinct points have disjoint neighbourhoods. The set $\{f = g\}$ is the preimage of Δ under the continuous map $(f, g) \colon Z \to X \times X$, and the graph of $f \colon Y \to X$ is $\{(y, x) : f(y) = x\}$, the equaliser of $f \circ p_1$ and p_2. □

Exercise 18.15.2. Show that $\overline{\prod_i A_i} = \prod_i \overline{A_i}$ in a product of spaces.

Solution. A point x lies in the closure of $\prod_i A_i$ if and only if every basic open set $\prod_i U_i \ni x$ meets $\prod_i A_i$, that is, $U_i \cap A_i \neq \emptyset$ for the finitely many i with $U_i \neq X_i$. This holds for all such sets if and only if $x_i \in \overline{A_i}$ for every i. □

Exercise 18.15.3. Show that $\mathbb{RP}^n$ is a compact Hausdorff space, and that the projection $S^n \to \mathbb{RP}^n$ is open.

Solution. If $U \subseteq S^n$ is open, $q^{-1}(q(U)) = U \cup (-U)$ is open, so q is open. Given $[x] \neq [y]$, we have $x \neq \pm y$; choose $\varepsilon < \min(\|x-y\|, \|x+y\|)/2$. The open sets $U = (B(x,\varepsilon) \cup B(-x,\varepsilon)) \cap S^n$ and $V = (B(y,\varepsilon) \cup B(-y,\varepsilon)) \cap S^n$ are invariant under $x \mapsto -x$ and disjoint, so $q(U)$ and $q(V)$ are disjoint open neighbourhoods. Compactness was shown in Example 18.6.10. □

Exercise 18.15.4. Prove the Baire category theorem for locally compact Hausdorff spaces.

Solution. Let $U_1, U_2, \ldots$ be dense open and W nonempty open. By Lemma 18.9.5, choose nonempty open sets V_n with compact closure and $\overline{V_1} \subseteq W \cap U_1$, $\overline{V_{n+1}} \subseteq V_n \cap U_{n+1}$. The compact sets $\overline{V_n}$ are nested and nonempty, so their intersection is nonempty: otherwise the open sets $\overline{V_1} \setminus \overline{V_n}$ would cover $\overline{V_1}$ without finite subcover. A point of the intersection lies in $W \cap \bigcap_n U_n$. □

Exercise 18.15.5. Let X be a metric space. Show that $x \mapsto d(x,-) - d(x_0,-)$ is an isometric embedding of X into the Banach space $C_b(X,\mathbb{R})$, for a fixed $x_0 \in X$, and deduce that X has a *completion*: a complete metric space containing X as a dense subspace.

Solution. The function $\phi_x = d(x,-) - d(x_0,-)$ is bounded by $d(x,x_0)$ and continuous. By the triangle inequality $|\phi_x(z) - \phi_y(z)| \le d(x,y)$ with equality at $z = y$, so $\|\phi_x - \phi_y\|_\infty = d(x,y)$. The closure of the image in the complete space $C_b(X,\mathbb{R})$ (Proposition 18.7.2) is complete and contains X as a dense subspace. □

Exercise 18.15.6. Show that the one-point compactification of $\mathbb{N}$ (discrete) is homeomorphic to $\{0\} \cup \{1/n : n \ge 1\} \subseteq \mathbb{R}$, and that $(0,1)^+$ is homeomorphic to S^1.

Exercise 18.15.7. Let $f\colon X \to Y$ be a continuous map between locally compact Hausdorff spaces. Show that f is proper if and only if its extension $f^+\colon X^+ \to Y^+$ with $f^+(\infty) = \infty$ is continuous.

Exercise 18.15.8. Let $q\colon X \to Y$ be a quotient map and K a compact Hausdorff space. Show that $q \times \mathrm{id}_K\colon X \times K \to Y \times K$ is a quotient map. (Hint: use the tube lemma from the proof of Proposition 18.6.4.)

Exercise 18.15.9. Show that $\operatorname{int}(A \cap B) = \operatorname{int} A \cap \operatorname{int} B$ but only $\operatorname{int}(A \cup B) \supseteq \operatorname{int} A \cup \operatorname{int} B$, with an example where the inclusion is strict.

Solution. $\operatorname{int} A \cap \operatorname{int} B$ is open and contained in $A \cap B$, hence in $\operatorname{int}(A \cap B)$; conversely $\operatorname{int}(A \cap B)$ is an open subset of A and of B. For unions, $\operatorname{int} A \cup \operatorname{int} B$ is an open subset of $A \cup B$. For $A = \mathbb{Q}$ and $B = \mathbb{R} \setminus \mathbb{Q}$ in $\mathbb{R}$, both interiors are empty while $\operatorname{int}(A \cup B) = \mathbb{R}$. □

Exercise 18.15.10. Show that $\partial A = \emptyset$ if and only if A is both open and closed, and deduce that a space is connected (Section 18.5) if and only if every subset other than $\emptyset$ and X has nonempty boundary.

Solution. $\partial A = \overline{A} \setminus \operatorname{int} A$ is empty if and only if $\overline{A} = \operatorname{int} A$, and since $\operatorname{int} A \subseteq A \subseteq \overline{A}$ this means $\operatorname{int} A = A = \overline{A}$, that is, A is open and closed. A space is connected exactly when its only clopen subsets are $\emptyset$ and X. □

Exercise 18.15.11. Let $f\colon X \to Y$ be continuous and surjective and $A \subseteq X$ dense. Show that $f(A)$ is dense in Y. Show also that two continuous maps $f, g\colon X \to Y$ to a Hausdorff space that agree on a dense subset are equal; give an example showing that the Hausdorff condition is needed.

Solution. $Y = f(X) = f(\overline{A}) \subseteq \overline{f(A)}$ by Proposition 18.2.13(3). The set $\{x : f(x) = g(x)\}$ is the preimage of the diagonal under (f, g), which is closed as Y is Hausdorff (Exercise 18.15.1); it contains the dense set, hence is everything. For Y the Sierpiński space $\{0, 1\}$ and $X = [0, 1]$, the constant map 1 and the map that is 0 at 0 and 1 elsewhere are continuous (the preimage of the open set $\{1\}$ is X, respectively $(0, 1]$) and agree on the dense set $(0, 1]$. □

Exercise 18.15.12. Let A be a nonempty subset of a metric space and $d(x, A) = \inf_{a\in A} d(x, a)$. Show that $|d(x, A) - d(y, A)| \leq d(x, y)$, so that $x \mapsto d(x, A)$ is continuous, and that $\overline{A} = \{x : d(x, A) = 0\}$. Deduce that every closed set in a metric space is the zero set of a continuous function, and that every open set is a countable union of closed sets.

Solution. For $a \in A$, $d(x, A) \leq d(x, a) \leq d(x, y) + d(y, a)$; taking the infimum over a gives $d(x, A) \leq d(x, y) + d(y, A)$, and symmetrically. If $d(x, A) = 0$ there are $a_n \in A$ with $d(x, a_n) \to 0$, so $x \in \overline{A}$; conversely if $d(x, A) = r > 0$, the ball $B(x, r)$ misses A. For C closed, $C = \{d(\cdot, C) = 0\}$, and an open U is the union of the closed sets $\{x : d(x, X \setminus U) \geq \frac{1}{n}\}$ (if $U \neq X$). □

Exercise 18.15.13. Let $S = \{0, 1\}$ be the Sierpiński space, with $\{1\}$ open. Show that continuous maps $X \to S$ correspond bijectively to open subsets of X, via $f \mapsto f^{-1}(1)$; and that continuous maps $X \to \{0, 1\}$ with the discrete topology correspond to subsets of X that are open and closed.

Solution. A map $f\colon X \to S$ is continuous if and only if the preimages of the three open sets $\emptyset$, $\{1\}$, S are open, that is, if and only if $f^{-1}(1)$ is open; and every subset U is $f^{-1}(1)$ for exactly one map, $f = \mathbf{1}_U$. For the discrete topology also $f^{-1}(0) = X \setminus f^{-1}(1)$ must be open. □

Chapter 19

Homotopy and Covering Spaces

19.1 Introduction

Homotopy theory studies spaces up to continuous deformation. Its first invariant is the fundamental group, which we compute for the circle using covering spaces (Theorem 19.4.6) and for spaces glued from simpler pieces using the Seifert–van Kampen theorem (Theorem 19.5.1). Covering spaces of a reasonable space are classified by subgroups of its fundamental group (Theorem 19.6.6), in close analogy with Galois theory. We then introduce CW complexes and the higher homotopy groups. Our main references are [Hat02] and [Spa66].

Prerequisites. Chapter 18 (General Topology) and Chapter 7 (Groups).

On the way to the Hodge conjecture. Needed: homotopy, the fundamental group and covering spaces (Sections 19.2 to 19.4). The Seifert–van Kampen theorem, the classification of coverings, CW complexes and higher homotopy groups are background for algebraic topology and can be postponed.

Throughout, $I = [0,1]$, $D^n = \{x \in \mathbb{R}^n : \|x\|_2 \le 1\}$ is the closed unit ball and $S^{n-1} = \partial D^n$ the unit sphere. A *map* of spaces means a continuous map.

19.2 Homotopy

Definition 19.2.1. A *homotopy* between maps $f, g\colon X \to Y$ is a map $H\colon X \times I \to Y$ with $H(x,0) = f(x)$ and $H(x,1) = g(x)$; we write $f \simeq g$ and $H_t = H(-,t)$. It is a homotopy *relative to* $A \subseteq X$ if $H_t(a) = f(a)$ for all $a \in A$ and $t \in I$. A map $f\colon X \to Y$ is a *homotopy equivalence* if there is $g\colon Y \to X$ with $gf \simeq \mathrm{id}_X$ and $fg \simeq \mathrm{id}_Y$; then X and Y are *homotopy equivalent*, $X \simeq Y$. A space is *contractible* if it is homotopy equivalent to a point. A subspace $A \subseteq X$ is a *retract* if there is a map $r\colon X \to A$ with $r|_A = \mathrm{id}_A$, and a *deformation retract* if moreover $ir \simeq \mathrm{id}_X$ relative to A, where $i\colon A \to X$ is the inclusion.

Lemma 19.2.2. *Homotopy (relative to A) is an equivalence relation on maps $X \to Y$, compatible with composition: if $f \simeq f'$ and $g \simeq g'$, then $gf \simeq g'f'$. Hence spaces and homotopy classes of maps form a category* hTop*, and homotopy equivalences are its isomorphisms.*

Proof. Reflexivity: $H(x,t) = f(x)$. Symmetry: $H(x, 1-t)$. Transitivity: if H goes from f to g and K from g to h, the map equal to $H(x,2t)$ for $t \le 1/2$ and $K(x,2t-1)$ for $t \ge 1/2$ is continuous by the pasting lemma (Lemma 18.4.5). If H goes from f to f' and K from g to g', then $(x,t) \mapsto K(H(x,t),t)$ goes from gf to $g'f'$; it is continuous as the composite of $(x,t) \mapsto (H(x,t),t)$ and K. Relative homotopies are preserved by these constructions. □

Example 19.2.3. 1. A convex subset $C \subseteq \mathbb{R}^n$ is contractible: for $c \in C$, the *straight-line homotopy* $H(x,t) = (1-t)x + tc$ goes from id_C to the constant map, and it is continuous

by Proposition 18.4.7(5). More generally, any two maps $f, g\colon X \to C$ are homotopic via $(1-t)f + tg$, relative to the set where they agree.

2. S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$ and of $D^n \setminus \{0\}$, via $H(x,t) = (1-t)x + tx/\|x\|$, which never vanishes.

Lemma 19.2.4. *If $q\colon X \to Y$ is a quotient map and K is a compact Hausdorff space, then $q \times \mathrm{id}_K\colon X \times K \to Y \times K$ is a quotient map. If $U \subseteq Y$ is open, then $q^{-1}(U) \to U$ is a quotient map.*

Proof. Let $W \subseteq Y \times K$ with $W' = (q \times \mathrm{id})^{-1}(W)$ open, and let $(y_0, k_0) \in W$ with $y_0 = q(x_0)$. The set $\{k : (x_0, k) \in W'\}$ is open and contains k_0; since K is regular (Proposition 18.8.3), there is an open $N \ni k_0$ whose closure $\overline{N}$ lies in it. Let $U' = \{x \in X : \{x\} \times \overline{N} \subseteq W'\}$, so $x_0 \in U'$. The set U' is open: for $x \in U'$, each (x,k) with $k \in \overline{N}$ has a basic neighbourhood $M_k \times O_k \subseteq W'$, finitely many O_k cover the compact set $\overline{N}$, and the intersection M of the corresponding M_k satisfies $M \times \overline{N} \subseteq W'$. It is saturated: if $q(x) = q(x')$ and $x \in U'$, then (x',k) and (x,k) have the same image, and W' is a union of fibres of $q \times \mathrm{id}$. So $q(U')$ is open, and $(y_0, k_0) \in q(U') \times N \subseteq W$. Hence W is open. For the second statement, if $V \subseteq U$ and $q^{-1}(V)$ is open in $q^{-1}(U)$, then it is open in X, so V is open in Y. □

Remark 19.2.5. A *deformation* of a space X is a homotopy $H\colon X \times I \to X$ starting at $H_0 = \mathrm{id}_X$: we watch X move continuously inside itself. By Definition 19.2.1, $A \subseteq X$ is a deformation retract if and only if there is a deformation H of X that ends in A ($H_1(X) \subseteq A$) and keeps every point of A fixed at all times ($H_t(a) = a$ for $a \in A$ and $t \in I$); then $r = H_1$, viewed as a map $X \to A$, is a retraction, and H is called a *deformation retraction*. Terminology varies: what we call a deformation retract is also called a *strong* deformation retract, and some authors call A a deformation retract as soon as there is a retraction r with $ir \simeq \mathrm{id}_X$, the homotopy not being required to fix A; we call this a *weak* deformation retract. Counterexample 19.2.9 shows that the two notions differ.

Lemma 19.2.6. 1. *If A is a deformation retract of X with retraction r, then the inclusion $i\colon A \to X$ and r are mutually inverse homotopy equivalences.*

2. *(Transitivity) If $A \subseteq B \subseteq X$, B is a deformation retract of X and A is a deformation retract of B, then A is a deformation retract of X.*

3. *(Products) If A is a deformation retract of X and B one of Y, then $A \times B$ is a deformation retract of $X \times Y$.*

Proof. (1) $ri = \mathrm{id}_A$ and $ir \simeq \mathrm{id}_X$. (2) Let H be a deformation retraction of X onto B with retraction r_B, and K one of B onto A with retraction r_A. Let $F(x,t) = H(x,2t)$ for $t \le 1/2$ and $F(x,t) = K(r_B(x), 2t-1)$ for $t \ge 1/2$; the two formulas agree at $t = 1/2$, where both give $r_B(x)$, so F is continuous by the pasting lemma (Lemma 18.4.5). It starts at id_X, ends at $r_A r_B(x) \in A$, and fixes every $a \in A$ at all times, since H fixes $B \supseteq A$, $r_B(a) = a$ and K fixes A. (3) If H and K are deformation retractions, so is $((x,y),t) \mapsto (H(x,t), K(y,t))$. □

Definition 19.2.7. The *mapping cylinder* of a map $f\colon X \to Y$ is the quotient $M_f = ((X \times I) \sqcup Y)/\!\sim$, where $(x,1) \sim f(x)$ for $x \in X$. We write $[x,s]$ for the class of (x,s) and $[y]$ for that of y, and $j\colon X \to M_f$, $j(x) = [x,0]$.

Example 19.2.8. 1. The cylinder $X \times I$ deformation retracts onto $X \times \{0\}$, by $H((x,s),t) = (x, (1-t)s)$.

2. *The Möbius band onto its core circle.* Let $M = ([0,1] \times [-1,1])/\sim$ with $(0,y) \sim (1,-y)$, and let C be the image of $[0,1] \times \{0\}$, a circle. The homotopy $([x,y],t) \mapsto [x,(1-t)y]$ is well defined, because $(0,(1-t)y) \sim (1,-(1-t)y)$, and continuous, because the product of the quotient map with id_I is a quotient map (Lemma 19.2.4). It fixes C and ends in C, so C is a deformation retract of M and $M \simeq S^1$.

3. *Every map is an inclusion up to homotopy.* Let $f\colon X \to Y$ be a map. The maps $i\colon Y \to M_f$, $y \mapsto [y]$, and $r\colon M_f \to Y$, $[x,s] \mapsto f(x)$, $[y] \mapsto y$, are well defined and continuous, and $ri = \mathrm{id}_Y$, so i is a homeomorphism onto its image, which we identify with Y. The homotopy $H([x,s],t) = [x, s+t(1-s)]$, $H([y],t) = [y]$ is well defined (at $s=1$ both formulas give $[f(x)]$), continuous by Lemma 19.2.4, starts at the identity, fixes Y and ends at ir. So Y is a deformation retract of M_f, r is a homotopy equivalence by Lemma 19.2.6, and $f = r \circ j$: every map factors as a map j into a larger space followed by a homotopy equivalence.

4. *The punctured torus onto two circles.* Let $T = [0,1]^2/\sim$ be the torus, with $(x,0) \sim (x,1)$ and $(0,y) \sim (1,y)$, let $c = (1/2,1/2)$, and let $p \in T$ be its image. For $z \in Q = [0,1]^2 \setminus \{c\}$ let $\rho(z) = c + (z-c)/(2\|z-c\|_\infty)$, the point where the ray from c through z leaves the square, and $H(z,t) = (1-t)z + t\rho(z)$, which stays on that ray, hence in Q. Since H fixes the boundary of the square pointwise, it respects the identifications, and it induces a deformation retraction of $T \setminus \{p\}$ onto the image of the boundary; it is continuous because $Q \to T \setminus \{p\}$ is a quotient map (the second statement of Lemma 19.2.4, as Q is open and saturated), and so is its product with id_I. The image of the boundary is the union of the two circles given by the bottom and the left side, meeting in one point: a wedge of two circles (Example 19.5.4). The same argument shows that a closed orientable surface of genus g minus a point deformation retracts onto a wedge of $2g$ circles.

Counterexample 19.2.9. *A weak deformation retract that is not a deformation retract.* Let $C \subseteq \mathbb{R}^2$ be the *comb space*

$$C = ([0,1] \times \{0\}) \cup (\{0\} \times [0,1]) \cup \textstyle\bigcup_{n \geq 1} (\{1/n\} \times [0,1]),$$

and $p = (0,1)$. The space C is contractible: $(x,y,t) \mapsto (x,(1-t)y)$ deforms it into the segment $[0,1] \times \{0\}$, which contracts to $(0,0)$, and the constant map at $(0,0)$ is homotopic to the constant map at p along the path $\{0\} \times [0,1]$. So $\{p\}$ is a weak deformation retract of C. But it is not a deformation retract. Suppose H is a deformation of C fixing p at all times and ending at the constant map p. Let $U = \{z \in C : \|z-p\| < 1/2\}$. Since $H(p,t) = p$ for all t and I is compact, there is a neighbourhood V of p in C with $H(V \times I) \subseteq U$ (as in the proof of Lemma 19.2.4). Choose n with $q = (1/n,1) \in V$. Then $t \mapsto H(q,t)$ is a path in U from q to p. But $U \subseteq (\{0\} \cup \{1/n : n \geq 1\}) \times (1/2,1]$, and the first coordinate of a path in U is a continuous map from I into the set $\{0\} \cup \{1/n : n \geq 1\}$, which contains no interval, so it is constant by the intermediate value theorem. This contradicts that the path joins q to p.

19.3 The fundamental group

Definition 19.3.1. For paths $\gamma, \delta\colon I \to X$ with $\gamma(1) = \delta(0)$, the *concatenation* $\gamma * \delta$ is $\gamma(2s)$ for $s \leq 1/2$ and $\delta(2s-1)$ for $s \geq 1/2$ (first γ, then δ), and the *reverse* of γ is $\bar{\gamma}(s) = \gamma(1-s)$. We write $\gamma \simeq \delta$ for homotopy relative to $\{0,1\}$ and $[\gamma]$ for the class. A *loop* at x_0 is a path with $\gamma(0) = \gamma(1) = x_0$, and c_{x_0} denotes the constant loop.

Lemma 19.3.2. *Concatenation is compatible with $\simeq$, and for composable paths:*

1. $\gamma \circ \varphi \simeq \gamma$ *for every map* $\varphi\colon I \to I$ *with* $\varphi(0) = 0$ *and* $\varphi(1) = 1$;
2. $(\gamma * \delta) * \epsilon \simeq \gamma * (\delta * \epsilon)$, *and* $c_{\gamma(0)} * \gamma \simeq \gamma \simeq \gamma * c_{\gamma(1)}$;
3. $\gamma * \bar{\gamma} \simeq c_{\gamma(0)}$ *and* $\bar{\gamma} * \gamma \simeq c_{\gamma(1)}$.

Proof. If H and K are homotopies $\gamma \simeq \gamma'$ and $\delta \simeq \delta'$, then $H(-,t) * K(-,t)$ is a homotopy $\gamma * \delta \simeq \gamma' * \delta'$. (1) $H(s,t) = \gamma((1-t)\varphi(s) + ts)$. (2) Each side is the other composed with a piecewise affine φ as in (1): for instance $(\gamma * \delta) * \epsilon = (\gamma * (\delta * \epsilon)) \circ \varphi$ with φ affine on $[0, \frac{1}{4}]$, $[\frac{1}{4}, \frac{1}{2}]$, $[\frac{1}{2}, 1]$ mapping them to $[0, \frac{1}{2}]$, $[\frac{1}{2}, \frac{3}{4}]$, $[\frac{3}{4}, 1]$. (3) $H(s,t) = \gamma(2s(1-t))$ for $s \le 1/2$ and $H(s,t) = \gamma((2-2s)(1-t))$ for $s \ge 1/2$ is a homotopy from $\gamma * \bar{\gamma}$ to $c_{\gamma(0)}$; apply this to $\bar{\gamma}$ for the second statement. □

Definition 19.3.3. The *fundamental group* $\pi_1(X, x_0)$ is the set of classes of loops at x_0 with the multiplication $[\gamma][\delta] = [\gamma * \delta]$, which is a group by Lemma 19.3.2, with identity $[c_{x_0}]$ and inverse $[\gamma]^{-1} = [\bar{\gamma}]$. (The group is written multiplicatively; note that $[\gamma][\delta]$ means "first γ".) A map $f\colon (X, x_0) \to (Y, y_0)$ of pointed spaces induces a homomorphism $f_*[\gamma] = [f \circ \gamma]$, and $(gf)_* = g_* f_*$, $\mathrm{id}_* = \mathrm{id}$. A path-connected space X is *simply connected* if $\pi_1(X, x_0)$ is trivial.

Lemma 19.3.4. *A path* h *from* x_0 *to* x_1 *induces an isomorphism* $\beta_h\colon \pi_1(X, x_0) \to \pi_1(X, x_1)$, $[\gamma] \mapsto [\bar{h} * \gamma * h]$. *If* H *is a homotopy from* f *to* $g\colon X \to Y$ *and* $h(t) = H(x_0, t)$, *then* $g_* = \beta_h \circ f_*\colon \pi_1(X, x_0) \to \pi_1(Y, g(x_0))$. *Consequently a homotopy equivalence induces isomorphisms on fundamental groups, and contractible spaces are simply connected.*

Proof. β_h is a homomorphism by Lemma 19.3.2, with inverse $\beta_{\bar{h}}$. For the second statement let γ be a loop at x_0 and $F(s,t) = H(\gamma(s), t)$ on the square I^2. In the convex set I^2, the path along the bottom and then the right side and the path along the left side and then the top have the same endpoints, so they are homotopic relative to the endpoints (Example 19.2.3(1)). Composing with F gives $(f \circ \gamma) * h \simeq h * (g \circ \gamma)$, that is, $g_*[\gamma] = [\bar{h} * (f \circ \gamma) * h]$.

Let f be a homotopy equivalence with inverse g. Since $gf \simeq \mathrm{id}_X$, the composite $\pi_1(X, x_0) \xrightarrow{f_*} \pi_1(Y, f(x_0)) \xrightarrow{g_*} \pi_1(X, gf(x_0))$ is β_h, a bijection. Since $fg \simeq \mathrm{id}_Y$, the composite $\pi_1(Y, f(x_0)) \xrightarrow{g_*} \pi_1(X, gf(x_0)) \xrightarrow{f_*} \pi_1(Y, fgf(x_0))$ is also a bijection. So this g_* is injective and surjective, hence bijective, and then $f_* = g_*^{-1}(g_* f_*)$ is bijective. □

Proposition 19.3.5. $\pi_1(X \times Y, (x_0, y_0)) \cong \pi_1(X, x_0) \times \pi_1(Y, y_0)$ *via the projections.*

Proof. Loops and homotopies in $X \times Y$ are pairs of loops and homotopies in X and Y (Proposition 18.4.7(2)). □

19.4 Covering spaces and the circle

Definition 19.4.1. A *covering map* is a surjective map $p\colon E \to B$ such that every $b \in B$ has an open neighbourhood U that is *evenly covered*: $p^{-1}(U)$ is a disjoint union of open sets (the *sheets* over U), each mapped homeomorphically onto U by p. A *lift* of a map $f\colon Y \to B$ is a map $\tilde{f}\colon Y \to E$ with $p\tilde{f} = f$.

Lemma 19.4.2 (Unique lifting)**.** *Let* $p\colon E \to B$ *be a covering map and* Y *connected. Two lifts of* $f\colon Y \to B$ *that agree at one point are equal.*

Proof. Let $\tilde{f}_1, \tilde{f}_2$ be lifts, $y \in Y$, U an evenly covered neighbourhood of $f(y)$, and $\tilde{U}_1, \tilde{U}_2$ the sheets containing $\tilde{f}_1(y), \tilde{f}_2(y)$. On the open neighbourhood $N = \tilde{f}_1^{-1}(\tilde{U}_1) \cap \tilde{f}_2^{-1}(\tilde{U}_2)$ of y: if $\tilde{f}_1(y) = \tilde{f}_2(y)$, then $\tilde{U}_1 = \tilde{U}_2$ and, p being injective on it, $\tilde{f}_1 = \tilde{f}_2$ on N; if $\tilde{f}_1(y) \neq \tilde{f}_2(y)$, then $\tilde{U}_1 \neq \tilde{U}_2$ (as p is injective on sheets), the sheets are disjoint and $\tilde{f}_1 \neq \tilde{f}_2$ on N. So the set where the lifts agree is open and closed, and nonempty, hence all of Y. □

Proposition 19.4.3 (Homotopy lifting)**.** *Let $p\colon E \to B$ be a covering map, $F\colon Y \times I \to B$ a homotopy and $\tilde{F}_0\colon Y \to E$ a lift of $F(-,0)$. There is a unique lift $\tilde{F}\colon Y\times I \to E$ of F with $\tilde{F}(-,0) = \tilde{F}_0$. In particular (for Y a point) every path in B has a unique lift with a given initial point.*

Proof. Fix $y_0 \in Y$. Each (y_0, t) has a neighbourhood $N_t \times J_t$ mapped by F into an evenly covered set. By compactness of I there are an open $N \ni y_0$ and a partition $0 = t_0 < t_1 < \cdots < t_m = 1$ with $F(N \times [t_i, t_{i+1}]) \subseteq U_i$, U_i evenly covered (intersect finitely many N_t, and take a partition subordinate to a Lebesgue number of the cover (J_t), Lemma 18.7.3). Suppose a lift $\tilde{F}$ has been constructed on $N \times [0, t_i]$ (for $i = 0$ this is $\tilde{F}_0$ on $N \times \{0\}$). Let $\tilde{U}_i$ be the sheet over U_i containing $\tilde{F}(y_0, t_i)$; replacing N by the open set $\{y \in N : \tilde{F}(y, t_i) \in \tilde{U}_i\}$, define $\tilde{F} = (p|_{\tilde{U}_i})^{-1} \circ F$ on $N \times [t_i, t_{i+1}]$; this agrees on $N \times \{t_i\}$ with the previous definition, and the pasting lemma gives a lift on $N \times [0, t_{i+1}]$. After m steps we have a lift on $N_{y_0} \times I$ for an open $N_{y_0} \ni y_0$.

For each y, the restrictions to $\{y\}\times I$ of two lifts agreeing at $(y, 0)$ coincide, by Lemma 19.4.2. Hence the lifts on the sets $N_{y_0} \times I$ agree on overlaps, glue to a continuous lift on $Y \times I$ (pasting lemma for the open cover), and this lift is unique. □

Corollary 19.4.4. *Let $p\colon E \to B$ be a covering map, $e_0 \in E$ and $b_0 = p(e_0)$.*

1. *If $\gamma \simeq \gamma'$ are paths starting at b_0, their lifts starting at e_0 have the same endpoint and are homotopic.*

2. *$p_*\colon \pi_1(E, e_0) \to \pi_1(B, b_0)$ is injective, and its image consists of the classes of loops whose lift starting at e_0 is a loop.*

3. *The* monodromy *$e \cdot [\gamma] = \tilde{\gamma}_e(1)$, where $\tilde{\gamma}_e$ is the lift of γ starting at e, is a right action of $\pi_1(B, b_0)$ on the fibre $p^{-1}(b_0)$. If E is path-connected, the action is transitive and the stabiliser of e_0 is $p_*\pi_1(E, e_0)$; so the fibre is in bijection with the set of right cosets of $p_*\pi_1(E, e_0)$.*

Proof. (1) Lift a homotopy F from γ to γ' with $\tilde{F}(-,0) = \tilde{\gamma}$ (Proposition 19.4.3). The paths $t \mapsto \tilde{F}(0,t)$ and $t \mapsto \tilde{F}(1,t)$ lift constant paths, so they are constant by uniqueness (Lemma 19.4.2); hence $\tilde{F}(-,1)$ is the lift of γ' starting at e_0 and has the same endpoint as $\tilde{\gamma}$. (2) If $p \circ \tilde{\gamma} \simeq c_{b_0}$ for a loop $\tilde{\gamma}$, lifting the homotopy gives $\tilde{\gamma} \simeq c_{e_0}$ by (1). If the lift of γ is a loop $\tilde{\gamma}$, then $[\gamma] = p_*[\tilde{\gamma}]$; conversely the lift of $p \circ \tilde{\gamma}$ is $\tilde{\gamma}$, and (1) handles homotopic loops. (3) The action is well defined by (1), and the lift of $\gamma * \delta$ starting at e is $\tilde{\gamma}_e * \tilde{\delta}_{e\cdot[\gamma]}$, so $e \cdot ([\gamma][\delta]) = (e \cdot [\gamma]) \cdot [\delta]$. If η is a path from e_0 to e, then $e_0 \cdot [p \circ \eta] = e$. The stabiliser statement is (2). □

Proposition 19.4.5. *Let $Q = \{x \in \mathbb{R}^2 : \|x\|_\infty = 1\}$ and let $P\colon \mathbb{R} \to Q$ be the map of period 4 that on $[0,4]$ runs affinely through the vertices $(1,-1)$, $(1,1)$, $(-1,1)$, $(-1,-1)$, $(1,-1)$ at the times $0,1,2,3,4$. Let $r\colon Q \to S^1$, $x \mapsto x/\|x\|_2$, and $p = r \circ P$. Then p is a covering map, $p(t) = p(t')$ if and only if $t - t' \in 4\mathbb{Z}$, and $p(t+4) = p(t)$.*

Proof. P is continuous by the pasting lemma (applied to the closed intervals $[k, k+1]$ inside each bounded open interval), and r is a homeomorphism with inverse $x \mapsto x/\|x\|_\infty$ (Example 18.6.10). By construction P is injective on $[a, a+4)$ for every a and has period 4, which gives the second statement. For $a \in \mathbb{R}$, the restriction $P|_{[a,a+4]}$ is a closed map (Proposition 18.6.3(4)). If $V \subseteq (a, a+4)$ is open, then $P(V) = Q \setminus P([a, a+4] \setminus V)$, because P is surjective, injective on $(a, a+4)$ and identifies only a and $a+4$; so $P(V)$ is open, and P maps $(a, a+4)$ homeomorphically onto $Q \setminus \{P(a)\}$. Given $q \in Q$, choose a with $P(a) \neq q$; then $U = Q \setminus \{P(a)\}$ is an open neighbourhood of q with $P^{-1}(U) = \bigsqcup_{k\in\mathbb{Z}}(a + 4k, a + 4k + 4)$, each interval mapped homeomorphically onto U. Composing with r proves that p is a covering map. □

Theorem 19.4.6. *Let $b_0 = p(0)$ and $\omega(s) = p(4s)$. Then $\pi_1(S^1, b_0) \cong \mathbb{Z}$, with $[\omega]$ corresponding to 1. Hence $\pi_1(S^1, x) \cong \mathbb{Z}$ for every $x \in S^1$.*

Proof. The space $\mathbb{R}$ is contractible, hence simply connected (Lemma 19.3.4), and path-connected. By Corollary 19.4.4(3), $[\gamma] \mapsto 0 \cdot [\gamma]$ is a bijection from $\pi_1(S^1, b_0)$ onto $p^{-1}(b_0) = 4\mathbb{Z}$. If the lifts of γ and δ starting at 0 end at $4m$ and $4n$, then $t \mapsto \tilde{\delta}_0(t) + 4m$ lifts δ (as p has period 4) and starts at $4m$, so the lift of $\gamma * \delta$ ends at $4(m+n)$. So $[\gamma] \mapsto \tilde{\gamma}_0(1)/4$ is an isomorphism onto $\mathbb{Z}$, and $\tilde{\omega}_0(s) = 4s$ ends at 4. The last statement follows from Lemma 19.3.4. □

Remark 19.4.7. With the exponential function of Chapter 27, the usual covering is $\mathbb{R} \to S^1$, $t \mapsto (\cos 2\pi t, \sin 2\pi t)$. We used a piecewise affine model so as not to depend on analysis. A map $f : S^1 \to S^1$ induces multiplication by an integer $\deg f$ on $\pi_1(S^1) \cong \mathbb{Z}$ (after identifying basepoints by a path, which does not matter since $\mathbb{Z}$ is abelian), its *degree*.

Corollary 19.4.8 (Brouwer fixed point theorem in dimension 2)**.** *There is no retraction $D^2 \to S^1$, and every map $f : D^2 \to D^2$ has a fixed point.*

Proof. If $r : D^2 \to S^1$ were a retraction with inclusion i, then $r_* i_* = \mathrm{id}$ on $\pi_1(S^1) \cong \mathbb{Z}$ would factor through $\pi_1(D^2) = 0$. If f had no fixed point, let $u(x) = x - f(x) \neq 0$ and $r(x) = x + \lambda(x)u(x)$, where

$$\lambda(x) = \frac{-\langle x, u\rangle + \sqrt{\langle x, u\rangle^2 + \|u\|^2(1 - \|x\|^2)}}{\|u\|^2}$$

is the non-negative solution of $\|x + \lambda u\|^2 = 1$. The square root is continuous on $[0, \infty)$ since $|\sqrt{a} - \sqrt{b}| \leq \sqrt{|a - b|}$, so r is continuous, and $r(x) \in S^1$. If $\|x\| = 1$, then $\langle x, u\rangle = 1 - \langle x, f(x)\rangle \geq 0$ by Cauchy–Schwarz, so $\lambda(x) = 0$ and $r(x) = x$. This contradicts the first statement. □

Counterexample 19.4.9. A retract need not be a deformation retract, not even a weak one. A point $\{b\}$ of S^1 is a retract (take the constant map), but not a weak deformation retract: otherwise the inclusion would be a homotopy equivalence (as in Lemma 19.2.6(1)), so $\pi_1(S^1) \cong \pi_1(\{b\}) = 0$ by Lemma 19.3.4, contradicting Theorem 19.4.6. Likewise the circle $S^1 \times \{b\}$ is a retract of the torus $S^1 \times S^1$ (via the first projection), but not a weak deformation retract, since $\pi_1(S^1 \times S^1) \cong \mathbb{Z}^2$ (Proposition 19.3.5) is not isomorphic to $\mathbb{Z}$ ($\mathbb{Z}^2/2\mathbb{Z}^2$ has four elements and $\mathbb{Z}/2\mathbb{Z}$ two). And by Corollary 19.4.8, S^1 is not even a retract of D^2, although it is a deformation retract of $D^2 \setminus \{0\}$ (Example 19.2.3(2)).

Example 19.4.10.

1. For $n \geq 1$ the map $S^1 \to S^1$, $p(t) \mapsto p(nt)$, is well defined and is a covering map with n sheets; it corresponds to the subgroup $n\mathbb{Z} \subseteq \mathbb{Z}$ in Theorem 19.6.6.
2. The projection $q : S^n \to \mathbb{RP}^n$ is a two-sheeted covering: for $x \in S^n$ the open hemisphere $W = \{y \in S^n : \langle x, y\rangle > 0\}$ is mapped injectively by q, $q^{-1}(q(W)) = W \sqcup (-W)$ is open, so $q(W)$ is open and $q|_W$, $q|_{-W}$ are homeomorphisms onto it (q is open, since $q^{-1}(q(V)) = V \cup (-V)$). For $n \geq 2$, S^n is simply connected (Corollary 19.5.2), so $\pi_1(\mathbb{RP}^n) \cong \mathbb{Z}/2\mathbb{Z}$ by Corollary 19.4.4(3).

19.5 The Seifert–van Kampen theorem

Theorem 19.5.1 (Seifert–van Kampen)**.** *Let $X = U \cup V$ with U, V open and U, V, $U \cap V$ path-connected, and $x_0 \in U \cap V$. The homomorphism*

$$\Phi : \pi_1(U, x_0) *_{\pi_1(U \cap V, x_0)} \pi_1(V, x_0) \to \pi_1(X, x_0)$$

induced by the inclusions (Proposition 7.10.7) is an isomorphism.

Proof. Write G for the amalgamated product and ι_U, ι_V for the maps from $\pi_1(U)$, $\pi_1(V)$ to G; by Definition 7.10.6, G is generated by their images. For loops $\gamma_1, \dots, \gamma_k$ at x_0 let $\gamma_1 \cdots \gamma_k$ denote the loop running through γ_i on $[(i-1)/k, i/k]$; it is homotopic to the iterated concatenation by Lemma 19.3.2(1).

Surjectivity. Let γ be a loop at x_0. By the Lebesgue number lemma there is a partition $0 = s_0 < \cdots < s_m = 1$ such that each $\gamma([s_{i-1}, s_i])$ lies in a set $A_i \in \{U, V\}$; merging adjacent intervals with the same label, we may assume $A_i \neq A_{i+1}$, so $\gamma(s_i) \in U \cap V$ for $0 < i < m$. Choose paths g_i in $U \cap V$ from x_0 to $\gamma(s_i)$, with g_0, g_m constant. Then $\gamma \simeq \prod_i (g_{i-1} * \gamma|_{[s_{i-1}, s_i]} * \bar{g}_i)$ (with the restriction reparametrised to I), a product of loops in U or V.

Injectivity. Let $\gamma_1, \dots, \gamma_k$ and $\gamma'_1, \dots, \gamma'_l$ be loops at x_0, each in U or V (label them A_i and A'_j), with $F \colon I \times I \to X$ a homotopy from $\gamma_1 \cdots \gamma_k$ to $\gamma'_1 \cdots \gamma'_l$ relative to $\{0, 1\}$. We show $\prod_i \iota_{A_i}[\gamma_i] = \prod_j \iota_{A'_j}[\gamma'_j]$ in G. This proves that $\ker \Phi$ is trivial: an element of the kernel can be written as $\prod_i \iota_{A_i}[\gamma_i]$, and $\gamma_1 \cdots \gamma_k$ is then homotopic to the constant loop, which we take as γ'_1 with $l = 1$.

Choose N divisible by k and l such that each small square R of the grid of mesh $1/N$ is mapped by F into U or V (Lebesgue number lemma), and fix a label $A_R \in \{U, V\}$ with $F(R) \subseteq A_R$. For each grid vertex v let S_v be the intersection of the labels of the squares containing v and, for v on the bottom (top) edge in the domain of γ_i (γ'_j), also of A_i (A'_j). Then S_v is U, V or $U \cap V$, so it is path-connected, and it contains $F(v)$. Choose a path g_v in S_v from x_0 to $F(v)$, constant if $F(v) = x_0$ and v lies on the boundary of the square. For an edge e from v to w let $\ell_e = g_v * F|_e * \bar{g}_w$, a loop in the intersection of the labels of the (one or two) squares containing e. Put $\phi(e) = \iota_{A_R}[\ell_e]$ for a square R containing e; this does not depend on R, because if two squares with different labels contain e, then ℓ_e lies in $U \cap V$ and the two images agree in G by the amalgamation relations. For an edge path P let $\phi(P)$ be the product of the $\phi(e)$ along P.

For a square R with lower left vertex a, lower right b, upper left c and upper right d, all four loops ℓ_e of its edges lie in A_R, and $F|_R$ gives, in the convex set R, a homotopy relative to endpoints in A_R between $F|_{[a,b]} * F|_{[b,d]}$ and $F|_{[a,c]} * F|_{[c,d]}$. Hence $[\ell_{ab}][\ell_{bd}] = [g_a * F|_{[a,b]} * F|_{[b,d]} * \bar{g}_d] = [\ell_{ac}][\ell_{cd}]$ in $\pi_1(A_R)$. So replacing the two lower-right edges of a square by its two upper-left edges does not change $\phi(P)$, and moving square by square the path P_0 along the bottom and right sides of I^2 to the path P_1 along the left and top sides gives $\phi(P_0) = \phi(P_1)$. On the vertical sides F is constant at x_0 and all g_v are constant, so those edges contribute 1. The bottom edges in the domain of γ_i have loops ℓ_e in A_i, and their product in $\pi_1(A_i)$ is $[\gamma_i]$ (the paths g_v cancel, and g_v is constant at the ends of the domain); since each ℓ_e also lies in A_R, $\iota_{A_R}[\ell_e] = \iota_{A_i}[\ell_e]$. Hence $\phi(P_0) = \prod_i \iota_{A_i}[\gamma_i]$, and likewise $\phi(P_1) = \prod_j \iota_{A'_j}[\gamma'_j]$. □

Corollary 19.5.2. *For $n \geq 2$ the sphere S^n is simply connected. If $X = U \cup V$ as in Theorem 19.5.1 with $U \cap V$ simply connected, then $\pi_1(X) \cong \pi_1(U) * \pi_1(V)$; if V is simply connected, then $\pi_1(U) \to \pi_1(X)$ is surjective with kernel the normal subgroup generated by the image of $\pi_1(U \cap V)$.*

Proof. Let $U = S^n \setminus \{N\}$ and $V = S^n \setminus \{-N\}$. By stereographic projection (Example 18.9.4), U and V are homeomorphic to $\mathbb{R}^n$, hence contractible, and $U \cap V$ is homeomorphic to $\mathbb{R}^n \setminus \{0\}$, which is path-connected for $n \geq 2$. So $\pi_1(S^n) \cong 1 *_{\pi_1(U \cap V)} 1 = 1$. The other statements follow from the presentation of the amalgamated product (Definition 7.10.6): the relations from $\pi_1(U \cap V)$ are trivial in the first case, and in the second they identify the image of each $h \in \pi_1(U \cap V)$ in $\pi_1(U)$ with 1. □

Example 19.5.3. Combining what we have proved so far:

1. A convex set, or any contractible space, has trivial fundamental group (Lemma 19.3.4).

2. $\pi_1(\mathbb{R}^n \setminus \{0\}) \cong \pi_1(S^{n-1})$, since S^{n-1} is a deformation retract (Example 19.2.3(2)); this is $\mathbb{Z}$ for $n = 2$ and trivial for $n \geq 3$ (Theorem 19.4.6 and Corollary 19.5.2). So $\mathbb{R}^2$ and $\mathbb{R}^n$, $n \geq 3$, are not homeomorphic: a homeomorphism would restrict to a homeomorphism of the complements of a point and its image.

3. The torus $T^2 = S^1 \times S^1$ has $\pi_1 \cong \mathbb{Z}^2$ by Proposition 19.3.5, generated by the two circles $S^1 \times \{*\}$ and $\{*\} \times S^1$; these commute, and the square relation $aba^{-1}b^{-1} = 1$ is the boundary of the square from which the torus is glued. Similarly $\pi_1(T^n) \cong \mathbb{Z}^n$, $\pi_1(S^1 \times S^2) \cong \mathbb{Z}$, and the solid torus $S^1 \times D^2$ and the Möbius band (Example 19.2.8(2)) have $\pi_1 \cong \mathbb{Z}$.

4. The circle is not a retract of the disc, and the identity of S^1 is not null-homotopic: a retraction $D^2 \to S^1$ would make $\pi_1(S^1) \to \pi_1(D^2) = 0$ injective (Exercise 19.9.1). This is the argument behind Corollary 19.4.8.

Example 19.5.4. Let $X = S^1 \vee S^1$ be the wedge of two circles, the quotient of $S^1 \sqcup S^1$ identifying the two basepoints b_0 to a point x_0. Let U (V) be the union of the first (second) circle with the second (first) circle minus the point $-b_0$. The open arc $S^1 \setminus \{-b_0\}$ deformation retracts onto b_0 (it is homeomorphic to an open interval by Proposition 19.4.5), so U and V deformation retract onto the circles (Lemma 19.2.4 ensures continuity of the homotopies on the quotient), and $U \cap V$ is contractible. By Corollary 19.5.2, $\pi_1(S^1 \vee S^1) \cong \mathbb{Z} * \mathbb{Z}$, the free group on two generators. It is not abelian, although $\pi_1(S^1 \times S^1) \cong \mathbb{Z}^2$ by Proposition 19.3.5.

Proposition 19.5.5 (Attaching cells)**.** *Let X be path-connected, $n \geq 2$, $\varphi\colon S^{n-1} \to X$ a map, and $Y = X \cup_\varphi D^n$ the space obtained by attaching an n-cell (Example 18.4.11). Let $z_0 \in S^{n-1}$ and $x_0 = \varphi(z_0)$. The inclusion induces a surjection $\pi_1(X, x_0) \to \pi_1(Y, x_0)$. For $n = 2$ its kernel is the normal subgroup generated by $[\varphi \circ \omega]$, where ω is the loop of Theorem 19.4.6 based at z_0; for $n \geq 3$ it is an isomorphism.*

Proof. Let $q\colon X \sqcup D^n \to Y$ be the quotient map. For $C \subseteq X$ closed, $q^{-1}(q(C)) = C \sqcup \varphi^{-1}(C)$ is closed, so $q|_X$ is an embedding onto a closed subspace, which we identify with X; similarly q maps the open ball $\operatorname{int} D^n$ homeomorphically onto an open subset. Let $V = q(\operatorname{int} D^n)$, which is contractible, and $U = Y \setminus \{q(0)\}$. On $q^{-1}(U) \times I = (X \times I) \sqcup ((D^n \setminus \{0\}) \times I)$ define H as the projection on $X \times I$ and as $q((1-t)z + tz/\|z\|)$ on the second part; it respects the identifications, so by Lemma 19.2.4 it induces a homotopy on $U \times I$, which is a deformation retraction of U onto X. The set $U \cap V$ is homeomorphic to $\operatorname{int} D^n \setminus \{0\}$, which is path-connected and deformation retracts onto the sphere of radius $1/2$; so $\pi_1(U \cap V)$ is $\mathbb{Z}$ for $n = 2$ (generated by $c(s) = q(\omega(s)/2)$) and trivial for $n \geq 3$ (Corollary 19.5.2).

Work at the basepoint $y_1 = q(z_0/2) \in U \cap V$. By Corollary 19.5.2, $\pi_1(U, y_1) \to \pi_1(Y, y_1)$ is surjective with kernel the normal subgroup generated by the image of $\pi_1(U \cap V, y_1)$. Transport to x_0 along the path $\delta(t) = H(y_1, t)$ from y_1 to x_0: the inclusion $X \to U$ is a homotopy equivalence, and by Lemma 19.3.4 applied to the homotopy H, the class $[c]$ corresponds to $[\bar{\delta} * c * \delta] = [H_1 \circ c] = [\varphi \circ \omega]$ in $\pi_1(X, x_0)$. Since the change-of-basepoint isomorphisms β_δ in U and Y are compatible with the inclusion, the statement follows. □

19.6 Classification of covering spaces

In this section B is path-connected and locally path-connected. Then a covering space E is locally path-connected, being locally homeomorphic to B, and if E is connected it is path-connected (Proposition 18.5.7).

Proposition 19.6.1 (Lifting criterion)**.** *Let $p\colon (E,e_0)\to(B,b_0)$ be a covering map, Y path-connected and locally path-connected, and $f\colon (Y,y_0)\to(B,b_0)$ a map. A lift $\tilde f\colon (Y,y_0)\to(E,e_0)$ exists if and only if $f_*\pi_1(Y,y_0)\subseteq p_*\pi_1(E,e_0)$, and it is then unique.*

Proof. Necessity follows from $f_*=p_*\tilde f_*$, and uniqueness from Lemma 19.4.2. Conversely, for $y\in Y$ choose a path η from y_0 to y and let $\tilde f(y)$ be the endpoint of the lift of $f\circ\eta$ starting at e_0. If η' is another such path, the loop $h=(f\circ\eta')*(f\circ\bar\eta)$ represents an element of $f_*\pi_1(Y)\subseteq p_*\pi_1(E)$, so its lift starting at e_0 is a loop (Corollary 19.4.4(2)). This lift is the lift of $f\circ\eta'$, ending at some e', followed by the lift of $f\circ\bar\eta$ starting at e', which therefore ends at e_0; reversing it gives the lift of $f\circ\eta$ starting at e_0, which ends at e'. So $\tilde f$ is well defined, and $p\tilde f=f$.

Continuity: let $y\in Y$, U an evenly covered neighbourhood of $f(y)$ and $\tilde U$ the sheet containing $\tilde f(y)$. Choose a path-connected open $W\ni y$ with $f(W)\subseteq U$. For $y'\in W$, using $\eta*\sigma$ with σ a path in W from y to y', the lift of $f\circ\sigma$ starting at $\tilde f(y)$ is $(p|_{\tilde U})^{-1}\circ f\circ\sigma$. So $\tilde f=(p|_{\tilde U})^{-1}\circ f$ on W. □

Definition 19.6.2. Two coverings $p\colon E\to B$ and $p'\colon E'\to B$ are *isomorphic* if there is a homeomorphism $\tau\colon E\to E'$ with $p'\tau=p$. The automorphisms of a covering form the group $\mathrm{Deck}(p)$ of *deck transformations*. A covering with E path-connected is *normal* (or Galois) if $\mathrm{Deck}(p)$ acts transitively on the fibres, and *universal* if E is simply connected.

Proposition 19.6.3. *Let $p\colon E\to B$ be a covering with E path-connected, $e_0\in p^{-1}(b_0)$ and $H=p_*\pi_1(E,e_0)$.*

1. *For $e\in p^{-1}(b_0)$ there is a deck transformation τ with $\tau(e_0)=e$ if and only if $p_*\pi_1(E,e)=H$. For $e=e_0\cdot[\gamma]$ one has $p_*\pi_1(E,e)=[\gamma]^{-1}H[\gamma]$.*

2. *The covering is normal if and only if H is a normal subgroup, and then $\mathrm{Deck}(p)\cong\pi_1(B,b_0)/H$. In particular, for a universal covering, $\mathrm{Deck}(p)\cong\pi_1(B,b_0)$.*

Proof. (1) If $p_*\pi_1(E,e)=H$, the lifting criterion gives maps $\tau,\tau'\colon E\to E$ over B with $\tau(e_0)=e$ and $\tau'(e)=e_0$; then $\tau'\tau$ and $\tau\tau'$ are lifts of p fixing a point, hence identities. The converse is clear. If $\tilde\gamma$ is the lift of γ from e_0 to e, then $[\tilde\alpha]\mapsto[\bar{\tilde\gamma}*\tilde\alpha*\tilde\gamma]$ is an isomorphism $\pi_1(E,e_0)\to\pi_1(E,e)$, whence the formula.

(2) The first statement follows from (1) and transitivity of monodromy (Corollary 19.4.4). A deck transformation commutes with monodromy, $\tau(e\cdot[\gamma])=\tau(e)\cdot[\gamma]$, since $\tau\circ\tilde\gamma_e$ lifts γ from $\tau(e)$. For H normal let $\Psi[\gamma]$ be the deck transformation with $\Psi[\gamma](e_0)=e_0\cdot[\gamma]$. Then $\Psi([\gamma][\delta])(e_0)=(e_0\cdot[\gamma])\cdot[\delta]=\Psi[\gamma](e_0\cdot[\delta])=\Psi[\gamma]\Psi[\delta](e_0)$, so Ψ is a homomorphism (deck transformations agreeing at a point are equal). It is surjective by (1), and its kernel is the stabiliser H of e_0. □

Definition 19.6.4. B is *semilocally simply connected* if every point b has a neighbourhood U such that $\pi_1(U,b)\to\pi_1(B,b)$ is trivial.

Theorem 19.6.5. *If B is path-connected, locally path-connected and semilocally simply connected, then B has a universal covering.*

Proof. Let $\tilde B$ be the set of classes $[\gamma]$ of paths starting at b_0 (up to homotopy relative to endpoints), and $p[\gamma]=\gamma(1)$. Let $\mathcal{U}$ be the set of path-connected open $U\subseteq B$ with $\pi_1(U)\to\pi_1(B)$ trivial (at any, hence every, basepoint in U). Every path-connected open subset of a member of $\mathcal{U}$ is in $\mathcal{U}$, so by the hypotheses $\mathcal{U}$ is a basis of B. For $U\in\mathcal{U}$ and $\gamma(1)\in U$ let $U_{[\gamma]}=\{[\gamma*\eta]:\eta\text{ a path in }U\text{ starting at }\gamma(1)\}$. Then $p\colon U_{[\gamma]}\to U$ is bijective: surjective as U is path-connected, and injective since for two paths η,η' in U with the same endpoints, $\eta*\bar\eta'$ is null-homotopic in B. If $[\gamma']\in U_{[\gamma]}$ then $U_{[\gamma']}=U_{[\gamma]}$. Hence if

$[\gamma''] \in U_{[\gamma]} \cap V_{[\gamma']}$, choosing $W \in \mathcal{U}$ with $\gamma''(1) \in W \subseteq U \cap V$ gives $[\gamma''] \in W_{[\gamma'']} \subseteq U_{[\gamma]} \cap V_{[\gamma']}$; so the sets $U_{[\gamma]}$ form a basis of a topology on $\tilde{B}$ (Lemma 18.2.10).

For $V \subseteq U$ in $\mathcal{U}$, p maps the basic open sets $V_{[\gamma']} \subseteq U_{[\gamma]}$ onto V, and $p^{-1}(V) \cap U_{[\gamma]} = V_{[\gamma']}$ for $[\gamma'] \in U_{[\gamma]}$ with $\gamma'(1) \in V$. So $p|_{U_{[\gamma]}}$ is a homeomorphism onto U. The set $p^{-1}(U)$ is the union of the sets $U_{[\gamma]}$ with $\gamma(1) \in U$, and two of them are equal or disjoint. So p is a covering map.

For $[\gamma] \in \tilde{B}$, let $\gamma_t(s) = \gamma(ts)$. The path $t \mapsto [\gamma_t]$ is continuous: near t_0, with $\gamma([t_0, t]) \subseteq U \in \mathcal{U}$, it equals $(p|_{U_{[\gamma_{t_0}]}})^{-1} \circ \gamma$. It is the lift of γ starting at $\tilde{b}_0 = [c_{b_0}]$ and ends at $[\gamma]$. So $\tilde{B}$ is path-connected, and a loop γ whose lift is a loop satisfies $[\gamma] = [c_{b_0}]$. By Corollary 19.4.4(2), $p_*\pi_1(\tilde{B}) = 1$, and as p_* is injective, $\tilde{B}$ is simply connected. □

Theorem 19.6.6 (Classification of coverings)**.** *Let B be path-connected, locally path-connected and semilocally simply connected, and $b_0 \in B$. Sending $p\colon (E, e_0) \to (B, b_0)$ to $p_*\pi_1(E, e_0)$ is a bijection between isomorphism classes of pointed coverings with E path-connected and subgroups of $\pi_1(B, b_0)$. Forgetting basepoints, isomorphism classes of coverings with E path-connected correspond to conjugacy classes of subgroups.*

Proof. Injectivity: if $p_*\pi_1(E, e_0) = p'_*\pi_1(E', e'_0)$, the lifting criterion gives pointed maps $E \to E'$ and $E' \to E$ over B, whose composites are identities by uniqueness of lifts.

Surjectivity: let $H \subseteq \pi_1(B, b_0)$ and $\tilde{B}$ be as in the proof of Theorem 19.6.5. Put $[\gamma] \sim [\gamma']$ if $\gamma(1) = \gamma'(1)$ and $[\gamma * \bar{\gamma}'] \in H$, an equivalence relation, and let $E_H = \tilde{B}/\!\sim$. If $[\gamma] \sim [\gamma']$ then $[\gamma * \eta] \sim [\gamma' * \eta]$, so the saturation of a basic set $U_{[\gamma]}$ is the union of the sets $U_{[\gamma']}$ with $[\gamma'] \sim [\gamma]$; hence the projection $\tilde{B} \to E_H$ is open, and the images of the sets $U_{[\gamma]}$ are open, pairwise equal or disjoint, and mapped bijectively (as distinct points of $U_{[\gamma]}$ have distinct endpoints), continuously and openly onto U. So $E_H \to B$ is a covering, and E_H is path-connected. The lift of a loop γ at b_0 starting at the class of $[c_{b_0}]$ is $t \mapsto$ class of $[\gamma_t]$, which is a loop if and only if $[\gamma] \in H$; by Corollary 19.4.4(2) the subgroup of E_H is H.

Changing the basepoint within the fibre replaces the subgroup by a conjugate, and every conjugate arises (Proposition 19.6.3); an isomorphism of unpointed coverings carries e_0 to some point of the fibre, which gives the last statement. □

Example 19.6.7. *Monodromy.* For a covering $p\colon E \to B$ and $b \in B$, lifting loops defines an action of $\pi_1(B, b)$ on the fibre $F = p^{-1}(b)$: $[\gamma]$ sends $e \in F$ to the endpoint of the lift of γ starting at e (Corollary 19.4.4), the *monodromy* of the covering. It is transitive when E is path-connected, and the stabiliser of e is $p_*\pi_1(E, e)$; so the fibre is $\pi_1(B, b)/p_*\pi_1(E, e)$, and the classification theorem says that connected coverings correspond to transitive π_1-sets. For the n-sheeted covering $S^1 \to S^1$, $p(t) \mapsto p(nt)$ (Example 19.4.10(1)), the fibre over $b_0 = p(0)$ consists of the points $p(4k/n)$, $0 \le k < n$, and the lift of the generator $\omega(s) = p(4s)$ starting at $p(4k/n)$ is $s \mapsto p(4(k + s)/n)$, which ends at $p(4(k + 1)/n)$: the generator acts by the cyclic permutation of the n points. For $S^n \to \mathbb{RP}^n$ the nontrivial element of $\pi_1(\mathbb{RP}^n) = \mathbb{Z}/2\mathbb{Z}$ exchanges the two antipodal points of a fibre. In complex analysis the same phenomenon appears for multivalued functions: continuing a branch of $\sqrt[n]{z}$ around the origin multiplies it by $e^{2\pi i/n}$, which is the monodromy of the covering $z \mapsto z^n$ of $\mathbb{C} \setminus 0$ (Chapter 29).

Counterexample 19.6.8. Semilocal simple connectivity is necessary: a space with a simply connected covering $p\colon E \to B$ is semilocally simply connected, because a loop in an evenly covered U lifts to a loop in a sheet, which is null-homotopic in E. The *Hawaiian earring*, the union of the circles of radius $1/n$ centred at $(1/n, 0)$ in $\mathbb{R}^2$, is path-connected and locally path-connected but not semilocally simply connected (every neighbourhood of the origin contains a whole circle, which is a retract of the earring and hence not null-homotopic in it), so it has no universal covering [Hat02].

19.7 CW complexes

Definition 19.7.1. A *CW complex* is a space X with an increasing sequence of subspaces $X^0 \subseteq X^1 \subseteq \cdots$, its *skeleta*, such that X^0 is discrete, X^n is obtained from X^{n-1} by attaching a family of n-cells, $X^n = (X^{n-1} \sqcup \coprod_\alpha D^n_\alpha)/(z \sim \varphi_\alpha(z))$ for maps $\varphi_\alpha \colon S^{n-1} \to X^{n-1}$, and $X = \bigcup_n X^n$ carries the final topology for the inclusions of the X^n (a set is open if and only if its intersection with every X^n is open). The images e^n_α of the open balls are the *open cells*, the maps $\Phi_\alpha \colon D^n_\alpha \to X$ are the *characteristic maps*, and X is *finite* if there are finitely many cells and *finite-dimensional* if $X = X^n$ for some n. A *subcomplex* is a closed union of cells containing, with each cell, the image of its characteristic map; (X, A) is then a *CW pair*.

Example 19.7.2.

1. S^n has a CW structure with one 0-cell and one n-cell attached by the constant map, since $D^n/S^{n-1} \cong S^n$. It also has a structure with two cells in each dimension $0, \dots, n$ (the hemispheres), compatible with the antipodal map.

2. Passing to the quotient by the antipodal map in the second structure gives $\mathbb{RP}^n$ one cell in each dimension $0, \dots, n$, with $\mathbb{RP}^n = \mathbb{RP}^{n-1} \cup e^n$ attached along the double covering $S^{n-1} \to \mathbb{RP}^{n-1}$. Similarly $\mathbb{CP}^n = \mathbb{CP}^{n-1} \cup e^{2n}$ has one cell in each even dimension (Example 19.7.3).

3. A graph is a 1-dimensional CW complex. The torus is obtained from $S^1 \vee S^1$ by attaching a 2-cell along the loop $aba^{-1}b^{-1}$, and the closed orientable surface of genus g from a wedge of $2g$ circles along $a_1 b_1 a_1^{-1} b_1^{-1} \cdots a_g b_g a_g^{-1} b_g^{-1}$. By Proposition 19.5.5 and Example 19.5.4 (extended to $2g$ circles), its fundamental group is $\langle a_1, b_1, \dots, a_g, b_g \mid \prod_i a_i b_i a_i^{-1} b_i^{-1} \rangle$.

Example 19.7.3. *Complex projective space, its cells and its fundamental group.* Let $\mathbb{CP}^n = (\mathbb{C}^{n+1} \setminus \{0\})/\mathbb{C}^\times$ be the space of complex lines in $\mathbb{C}^{n+1}$, with the quotient topology, and write $[z] = [z_0 : \cdots : z_n]$.

1. $\mathbb{CP}^n$ is compact and Hausdorff. It is compact, being the image of the compact sphere S^{2n+1}. The map $[z] \mapsto zz^*/\|z\|^2$ to the space of complex $(n+1) \times (n+1)$ matrices is well defined and continuous (Proposition 18.4.10), and injective, since $zz^*/\|z\|^2$ is the orthogonal projection onto the line $\mathbb{C}z$; a space with a continuous injection into a Hausdorff space is Hausdorff.

2. $\mathbb{CP}^n = \mathbb{CP}^{n-1} \cup e^{2n}$. The map $\mathbb{CP}^{n-1} \to \mathbb{CP}^n$, $[z'] \mapsto [z' : 0]$, is a continuous injection from a compact space to a Hausdorff space, hence a homeomorphism onto the closed set $\{z_n = 0\}$ (Proposition 18.6.3(4)). Let $\Phi \colon D^{2n} \to \mathbb{CP}^n$, $\Phi(w) = [w_1 : \cdots : w_n : (1 - \|w\|^2)^{1/2}]$ for $w \in \mathbb{C}^n = \mathbb{R}^{2n}$ with $\|w\| \le 1$. A point $[z]$ with $z_n \neq 0$ has exactly one representative with $\|z\| = 1$ and z_n real and positive, so Φ maps the open disc bijectively onto $\{z_n \neq 0\}$; on the boundary sphere S^{2n-1} it is the quotient map onto $\mathbb{CP}^{n-1}$. So Φ induces a continuous bijection $\mathbb{CP}^{n-1} \cup_{\Phi|_{S^{2n-1}}} D^{2n} \to \mathbb{CP}^n$ from a compact space onto a Hausdorff space, which is a homeomorphism. By induction, $\mathbb{CP}^n$ is a CW complex with one cell in each dimension $0, 2, \dots, 2n$. For $n = 1$, a 2-cell is attached to a point, so $\mathbb{CP}^1 \cong D^2/S^1 \cong S^2$ (Example 19.7.2(1)); an explicit homeomorphism is given in Chapter 20.

3. $\mathbb{CP}^n$ is simply connected. $\mathbb{CP}^0$ is a point, and attaching a 2-cell to a point gives a simply connected space, as π_1 of the point surjects onto it; attaching cells of dimension $2n \ge 4$ does not change π_1 (Proposition 19.5.5). So $\pi_1(\mathbb{CP}^n) = 1$ for all n by induction.

4. The same induction for $\mathbb{RP}^n = \mathbb{RP}^{n-1} \cup e^n$ does *not* give simple connectivity, because it starts from a circle. The map $S^1 \to S^1$, $z \mapsto z^2$, induces a continuous bijection

$\mathbb{RP}^1 = S^1/\{\pm 1\} \to S^1$, hence a homeomorphism, and in this identification the 2-cell of $\mathbb{RP}^2$ is attached along the double covering $z \mapsto z^2$, a loop representing $2 \in \mathbb{Z} \cong \pi_1(S^1)$ (Theorem 19.4.6). So $\pi_1(\mathbb{RP}^1) \cong \mathbb{Z}$, $\pi_1(\mathbb{RP}^2) \cong \mathbb{Z}/2\mathbb{Z}$ by Proposition 19.5.5, and the cells of dimension $n \geq 3$ do not change this: $\pi_1(\mathbb{RP}^n) \cong \mathbb{Z}/2\mathbb{Z}$ for $n \geq 2$, as found with covering spaces in Example 19.4.10(2).

Theorem 19.7.4. *Let X be a CW complex.*

1. *X is Hausdorff, and in fact paracompact, and it is locally contractible.*
2. *Every compact subset of X lies in a finite subcomplex.*
3. *(Homotopy extension property) If (X, A) is a CW pair, then $X \times \{0\} \cup A \times I$ is a deformation retract of $X \times I$; so every map $X \times \{0\} \cup A \times I \to Y$ extends to $X \times I$.*
4. *The inclusion $X^2 \to X$ induces an isomorphism on fundamental groups (at a 0-cell).*

These are [Hat02, Appendix, and Propositions 0.16 and 1.26]. Part (4) follows from Proposition 19.5.5 applied to the finite subcomplexes containing a given loop or homotopy, using (2).

Theorem 19.7.5 (Cellular approximation)**.** *Every map $f : X \to Y$ of CW complexes is homotopic to a* cellular *map ($f(X^n) \subseteq Y^n$ for all n), by a homotopy relative to any subcomplex on which f is already cellular.*

This is [Hat02, Theorem 4.8].

19.8 Higher homotopy groups and fibrations

Definition 19.8.1. For $n \geq 1$, $\pi_n(X, x_0)$ is the set of homotopy classes, relative to ∂I^n, of maps $f : (I^n, \partial I^n) \to (X, x_0)$, with $[f] + [g] = [f *_1 g]$, where $(f *_1 g)(s) = f(2s_1, s_2, \ldots, s_n)$ for $s_1 \leq 1/2$ and $g(2s_1 - 1, s_2, \ldots, s_n)$ for $s_1 \geq 1/2$. We write the operation additively for $n \geq 2$ and multiplicatively for $n = 1$, where it is the fundamental group. Also $\pi_0(X, x_0)$ is the pointed set of path components.

Proposition 19.8.2. *$\pi_n(X, x_0)$ is a group, abelian for $n \geq 2$. A pointed map induces homomorphisms f_*, pointed homotopic maps induce the same homomorphisms, and $\pi_n(X \times Y) \cong \pi_n(X) \times \pi_n(Y)$.*

Proof. The proofs of Lemma 19.3.2 apply verbatim in the first coordinate, the other coordinates being carried along. For $n \geq 2$ define $*_2$ in the same way using the second coordinate; it also induces a well-defined operation on π_n with the same identity e, the class of the constant map. For maps, $(a *_1 b) *_2 (c *_1 d) = (a *_2 c) *_1 (b *_2 d)$ holds exactly (both sides are a, b, c, d on the four quarters of $I^2 \times I^{n-2}$, rescaled). Hence on classes

$$a *_2 b = (a *_1 e) *_2 (e *_1 b) = (a *_2 e) *_1 (e *_2 b) = a *_1 b, \quad a *_1 b = (e *_1 a) *_2 (b *_1 e) = (e *_2 b) *_1 (a *_2 e) = b *_1 a$$

(the Eckmann–Hilton argument). The remaining statements are clear. □

Proposition 19.8.3. *A covering map $p : E \to B$ induces isomorphisms $\pi_n(E, e_0) \to \pi_n(B, b_0)$ for $n \geq 2$. In particular $\pi_n(S^1) = 0$ and $\pi_n(\mathbb{RP}^m) \cong \pi_n(S^m)$ for $n \geq 2$.*

Proof. For $n \geq 2$, ∂I^n is homeomorphic to S^{n-1} (by $x \mapsto x/\|x\|_2$ after centring, as in Example 18.6.10), hence path-connected. Let $f : (I^n, \partial I^n) \to (B, b_0)$. The cube is simply connected and locally path-connected, so f has a lift $\tilde{f}$ with $\tilde{f}(0) = e_0$ (Proposition 19.6.1); $\tilde{f}(\partial I^n)$ is a connected subset of the fibre $p^{-1}(b_0)$, which is discrete, so $\tilde{f}(\partial I^n) = e_0$. So p_* is

surjective. If $p \circ \tilde{f}$ is null-homotopic relative to ∂I^n, lift the homotopy (Proposition 19.4.3); the image of the connected set $\partial I^n \times I$ lies in the fibre, hence is e_0, and at time 1 the lift of the constant map is constant. So p_* is injective. Apply this to $\mathbb{R} \to S^1$ ($\mathbb{R}$ is contractible) and $S^m \to \mathbb{RP}^m$. □

Definition 19.8.4. A map $p\colon E \to B$ has the *homotopy lifting property* with respect to Y if for every homotopy $F\colon Y \times I \to B$ and lift $\tilde{F}_0$ of F_0 there is a lift $\tilde{F}$ of F with $\tilde{F}(-,0) = \tilde{F}_0$ (not necessarily unique). It is a *Hurewicz fibration* if this holds for all Y, and a *Serre fibration* if it holds for all cubes $Y = I^k$. The fibre over b_0 is $F = p^{-1}(b_0)$. For a pair (X, A) with $x_0 \in A$ and $n \geq 1$, the *relative homotopy group* $\pi_n(X, A, x_0)$ is the set of homotopy classes of maps $(I^n, \partial I^n, J^{n-1}) \to (X, A, x_0)$, where $J^{n-1} = \overline{\partial I^n \setminus I^{n-1} \times \{0\}}$; it is a group for $n \geq 2$.

Theorem 19.8.5 (Long exact sequences)**.** 1. *For a pair (X, A) there is a long exact sequence*
$$\cdots \to \pi_n(A) \to \pi_n(X) \to \pi_n(X, A) \xrightarrow{\partial} \pi_{n-1}(A) \to \cdots \to \pi_0(X), \text{ with } \partial[f] = [f|_{I^{n-1}\times\{0\}}].$$

2. *For a Serre fibration $p\colon E \to B$ with B path-connected, fibre F and $x_0 \in F$, the map $p_*\colon \pi_n(E, F, x_0) \to \pi_n(B, b_0)$ is an isomorphism for $n \geq 1$, which gives a long exact sequence*
$$\cdots \to \pi_n(F) \to \pi_n(E) \to \pi_n(B) \to \pi_{n-1}(F) \to \cdots \to \pi_0(E) \to 0.$$

Sketch of proof. (1) Exactness at each term is a direct manipulation of maps of cubes, based on the *compression criterion*: a map $f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, x_0)$ represents 0 if and only if it is homotopic relative to ∂I^n to a map into A. (2) Surjectivity of p_* lifts a map $(I^n, \partial I^n) \to (B, b_0)$, viewed as a homotopy of maps $I^{n-1} \to B$, starting from the constant lift; injectivity lifts a homotopy in the same way, using the homotopy lifting property for $I^{n-1} \times I$ relative to J^{n-1} (which holds for Serre fibrations because $(I^n, J^{n-1}) \cong (I^n, I^{n-1} \times \{0\})$). Substituting into (1) for the pair (E, F) gives the sequence. The omitted verifications are in [Hat02, Theorems 4.3 and 4.41]. □

Theorem 19.8.6 (Whitehead)**.** *A map between connected CW complexes that induces isomorphisms on all homotopy groups π_n, $n \geq 1$, is a homotopy equivalence.*

This is [Hat02, Theorem 4.5].

Counterexample 19.8.7. The theorem needs a *map* inducing the isomorphisms: abstractly isomorphic homotopy groups are not enough. Let $X = \mathbb{RP}^2 \times S^3$ and $Y = S^2 \times \mathbb{RP}^3$. Both have fundamental group $\mathbb{Z}/2\mathbb{Z}$ (Proposition 19.3.5 and Example 19.4.10(2), with $\pi_1(S^k) = 0$ for $k \geq 2$), and both have the universal covering $S^2 \times S^3$, so by Proposition 19.8.3 $\pi_n(X) \cong \pi_n(S^2 \times S^3) \cong \pi_n(Y)$ for all $n \geq 2$. But they are not homotopy equivalent: their second homology groups, which are homotopy invariants, are $H_2(X;\mathbb{Z}) = 0$ and $H_2(Y;\mathbb{Z}) \cong \mathbb{Z}$, by the Künneth formula (Chapter 21); see [Hat02, Example 4.35]. Also X is non-orientable and Y is orientable.

Remark 19.8.8. Higher homotopy groups are hard to compute. By cellular approximation, $\pi_k(S^n) = 0$ for $k < n$ (a map $S^k \to S^n$ is homotopic to a cellular map, which misses the open n-cell and so factors through a point). The *Hopf fibration* $S^3 \to S^2 = \mathbb{CP}^1$, $(z_1, z_2) \mapsto [z_1 : z_2]$, has fibre S^1, and its long exact sequence gives $\pi_3(S^2) \cong \pi_3(S^3) \cong \mathbb{Z}$, although $H_3(S^2) = 0$. Homology (Chapter 21) is much more computable, and the Hurewicz theorem relates the two.

19.9 Exercises

Exercise 19.9.1. Show that if $A \subseteq X$ is a retract, then $i_*\colon \pi_1(A,a) \to \pi_1(X,a)$ is injective, and if A is a deformation retract it is an isomorphism.

Solution. $r_* i_* = (ri)_* = \mathrm{id}$, so i_* is injective. For a deformation retract, $ir \simeq \mathrm{id}_X$ relative to A, so i is a homotopy equivalence and Lemma 19.3.4 applies (the path h is constant since $a \in A$ is fixed). □

Exercise 19.9.2. Let G be a topological group (a group with continuous multiplication and inversion) with identity 1. Show that $\pi_1(G,1)$ is abelian, and that the group law of π_1 coincides with $[\gamma][\delta] = [s \mapsto \gamma(s)\delta(s)]$.

Solution. Let $\gamma \cdot \delta$ denote the pointwise product. For loops, $(\gamma * \delta) \cdot (\gamma' * \delta') = (\gamma \cdot \gamma') * (\delta \cdot \delta')$ exactly, and the constant loop is a two-sided unit for both operations on classes. The Eckmann–Hilton argument of Proposition 19.8.2 shows that the two operations coincide and are commutative. □

Exercise 19.9.3. Show that every map $S^n \to S^1$ with $n \geq 2$ is null-homotopic, and that every map $S^1 \to S^1$ of degree 0 is null-homotopic.

Solution. In both cases $f_*\pi_1 = 0$ (S^n is simply connected for $n \geq 2$; for degree 0 by definition), so f lifts to $\tilde{f}\colon S^n \to \mathbb{R}$ by the lifting criterion. Then $f = p \circ \tilde{f} \simeq p \circ c$ via $p \circ ((1-t)\tilde{f} + tc)$, where c is a constant. □

Exercise 19.9.4. Show that the deck transformation group of $p\colon \mathbb{R} \to S^1$ consists of the translations $t \mapsto t + 4k$, $k \in \mathbb{Z}$, and deduce again $\pi_1(S^1) \cong \mathbb{Z}$ from Proposition 19.6.3.

Solution. Translations by multiples of 4 commute with p, since p has period 4. Conversely, if $\tau\colon \mathbb{R} \to \mathbb{R}$ is continuous with $p \circ \tau = p$, then $\tau(t) - t \in 4\mathbb{Z}$ for every t (Proposition 19.4.5), so $(\tau(t) - t)/4$ is a continuous integer-valued function on the connected space $\mathbb{R}$, hence constant. So the deck group is $\mathbb{Z}$. Since $\mathbb{R}$ is simply connected, p is a universal covering, and Proposition 19.6.3 identifies $\pi_1(S^1)$ with the deck group. □

Exercise 19.9.5. (Borsuk–Ulam in dimension 2.) Show that for every map $f\colon S^2 \to \mathbb{R}^2$ there is x with $f(x) = f(-x)$. (Hint: otherwise $g(x) = (f(x) - f(-x))/\|f(x) - f(-x)\|$ is an odd map $S^2 \to S^1$; restrict to the equator and compare lifts to $\mathbb{R}$ along a half circle.)

Solution. Suppose $f(x) \neq f(-x)$ for all x, and let g be as in the hint, so $g(-x) = -g(x)$. Let $h\colon S^1 \to S^1$ be the restriction of g to the equator. Let $\gamma\colon I \to S^1$ be a loop going once around the equator with $\gamma(s + \frac{1}{2}) = -\gamma(s)$ for $0 \leq s \leq \frac{1}{2}$, and $\tilde{h}$ a lift of $h \circ \gamma$ through p.

On the one hand, γ is null-homotopic in the upper hemisphere, which is homeomorphic to a disc by vertical projection, so $h \circ \gamma = g \circ \gamma$ is null-homotopic in S^1, and by Corollary 19.4.4(2) its lift is a loop: $\tilde{h}(1) = \tilde{h}(0)$. On the other hand: The covering p of Proposition 19.4.5 satisfies $p(t+2) = -p(t)$ (the point $P(t+2)$ is opposite to $P(t)$ on the square). Since h is odd, $p(\tilde{h}(s + \frac{1}{2})) = -p(\tilde{h}(s)) = p(\tilde{h}(s) + 2)$, so $\tilde{h}(s + \frac{1}{2}) - \tilde{h}(s) - 2 \in 4\mathbb{Z}$ for $s \in [0, \frac{1}{2}]$, and by continuity it is a constant $4k$. Then $\tilde{h}(1) - \tilde{h}(0) = 2(2 + 4k) = 4(1 + 2k)$, which is not 0. This contradiction proves the claim. (In the language of Theorem 19.4.6: an odd map $S^1 \to S^1$ has odd degree.) (For instance, at any moment there are two antipodal points on the Earth with the same temperature and pressure.) □

Exercise 19.9.6. Find all connected two-sheeted coverings of $S^1 \vee S^1$, and describe the covering corresponding to the kernel of $\mathbb{Z} * \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

Solution. By Theorem 19.6.6, connected two-sheeted coverings correspond to subgroups of index 2 of $\pi_1(S^1 \vee S^1) = F(a, b)$ (Example 19.5.4), up to conjugacy. A subgroup H of index 2 is normal (its left cosets and its right cosets are both H and its complement), so it is the kernel of a surjection $F(a, b) \to F(a, b)/H \cong \mathbb{Z}/2\mathbb{Z}$; such a homomorphism is determined by the images of a and b, which are not both zero, and different homomorphisms to $\mathbb{Z}/2\mathbb{Z}$ have different kernels. So there are three such subgroups. The coverings are graphs with two vertices, each with one incoming and one outgoing a-edge and b-edge, mapping to the wedge. For $a \mapsto 1, b \mapsto 0$: the two a-edges join the two vertices in a circle, and each vertex carries a b-loop. For $a \mapsto 0, b \mapsto 1$: the same with a and b exchanged. For $a, b \mapsto 1$: all four edges join the two vertices. The kernel of $F(a, b) \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ is normal of index 4, and the covering is the *Cayley graph* of $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$: four vertices, the elements of the group, with an a-edge from g to $g + (1, 0)$ and a b-edge from g to $g + (0, 1)$. It has 4 vertices and 8 edges; the fundamental group of a connected graph is free on the edges outside a maximal tree [Hat02, Proposition 1A.2], so this subgroup is free of rank $8 - 3 = 5$. □

Chapter 20

Topological Manifolds and Group Actions

20.1 Introduction

A topological manifold is a space that looks locally like $\mathbb{R}^n$. The definition has three axioms: locally Euclidean, Hausdorff and second countable. This chapter explains why each is there, by counterexamples showing that none follows from the other two (Section 20.5), and develops the two main ways of producing manifolds from old ones: quotients by group actions (Sections 20.2 to 20.4) and gluing (Section 20.8). The quotients of spheres by the unit elements of $\mathbb{R}$, $\mathbb{C}$ and the quaternions give the projective spaces and the Hopf fibrations $S^{2n+1} \to \mathbb{CP}^n$ and $S^{4n+3} \to \mathbb{HP}^n$, with their consequences for the homotopy groups of spheres (Section 20.7). Smooth structures come in Chapter 33, and homological invariants such as the dimension and the orientation in Chapter 23. References: [Mun00], [Hat02], [Lee13].

Prerequisites. Chapter 18 (General Topology), Chapter 19 (Homotopy and Covering Spaces), Chapter 7 (Groups) and, for the quaternions, Chapter 8 (Rings and Modules).

On the way to the Hodge conjecture. Needed: group actions and quotients, topological manifolds and the basic constructions, such as projective spaces (Section 20.3 to Section 20.6). Hopf fibrations and gluing (Sections 20.7, 20.8) can be postponed.

Conventions. Groups are written multiplicatively, with identity element e, unless stated otherwise; $\mathbb{R}^n$ and $\mathbb{Z}^n$ are groups under addition. A *neighbourhood* of a point is an open set containing it.

20.2 Topological groups

Definition 20.2.1. A *topological group* is a group G with a topology such that the multiplication $G \times G \to G, (g, h) \mapsto gh$, and the inversion $G \to G, g \mapsto g^{-1}$, are continuous. A *homomorphism* of topological groups is a continuous group homomorphism.

Example 20.2.2.

1. $(\mathbb{R}^n, +)$, $(\mathbb{C}, +)$, the multiplicative groups $\mathbb{R}^\times$, $\mathbb{R}_{>0}$ and $\mathbb{C}^\times$, and the circle $S^1 = \{z \in \mathbb{C} : |z| = 1\}$, with the Euclidean topologies: the operations are polynomial or rational.

2. $\mathrm{GL}_n(\mathbb{R})$ and $\mathrm{GL}_n(\mathbb{C})$, open subsets of the spaces of matrices $\mathbb{R}^{n^2}$ and $\mathbb{C}^{n^2}$ (as the complement of the zero set of det); multiplication is polynomial in the entries and inversion is rational by Cramer's rule. Their subgroups SL_n, $\mathrm{O}(n) = \{A : A^T A = I\}$, $\mathrm{SO}(n)$, $\mathrm{U}(n) = \{A : \bar{A}^T A = I\}$ and $\mathrm{SU}(n)$, with the subspace topologies. $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are compact, being closed and bounded (their columns are unit vectors).

3. Any group with the discrete topology; products of topological groups.

4. $(\mathbb{Q}, +)$ with the subspace topology, a topological group that is neither discrete nor locally compact.

Proposition 20.2.3. *Let G be a topological group.*

1. *For $g \in G$, left translation $h \mapsto gh$, right translation and inversion are homeomorphisms of G.*

2. *An open subgroup H is also closed.*

3. *Let U be a neighbourhood of e with $U = U^{-1}$. The subgroup generated by U is open. If G is connected, it is G.*

4. *The connected component G^0 of e is a closed normal subgroup.*

5. *G is Hausdorff if and only if $\{e\}$ is closed.*

Proof. (1) Left translation by g is continuous, as the composite of $h \mapsto (g, h)$ and multiplication, with continuous inverse left translation by g^{-1}; similarly on the right, and inversion is its own inverse. (2) The complement of H is the union of the cosets gH, $g \notin H$, which are open by (1). (3) The subgroup H generated by U is the union of the sets $u_1 \cdots u_k U$ with $u_i \in U$, which are open by (1). By (2) it is also closed, and nonempty, so $H = G$ if G is connected. (4) G^0G^0 is the image of the connected set $G^0 \times G^0$ under multiplication, hence connected, and it contains e; so $G^0G^0 \subseteq G^0$. Similarly $(G^0)^{-1} \subseteq G^0$ and $gG^0g^{-1} \subseteq G^0$ for all g. Components are closed. (5) If G is Hausdorff, points are closed. Conversely, if $\{e\}$ is closed, so is the diagonal $\{(g, h) : gh^{-1} = e\}$, the preimage of $\{e\}$ under the continuous map $(g, h) \mapsto gh^{-1}$. If $g \neq h$, then (g, h) lies in the open complement of the diagonal, so some product neighbourhood $A \times B$ of (g, h) misses the diagonal, that is, $A \cap B = \emptyset$. □

Counterexample 20.2.4. Any group with the indiscrete topology, whose only open sets are $\emptyset$ and G, is a topological group, and it is not Hausdorff if $|G| > 1$. So (5) is a genuine condition. More generally, for any normal subgroup N the quotient G/N with the quotient topology is a topological group, and it is Hausdorff if and only if N is closed (Exercise 20.9.1).

20.3 Group actions and orbit spaces

Definition 20.3.1. A (left) *action* of a topological group G on a space X is a continuous map $G \times X \to X$, $(g, x) \mapsto g \cdot x = gx$, with $ex = x$ and $g(hx) = (gh)x$. The *orbit* of x is $Gx = \{gx : g \in G\}$, the *stabiliser* is $G_x = \{g : gx = x\}$, and the *orbit space* X/G is the set of orbits with the quotient topology for the projection $\pi \colon X \to X/G$. The action is *free* if all stabilisers are trivial, and *transitive* if there is only one orbit.

Each $g \in G$ acts by a homeomorphism of X, with inverse the action of g^{-1}. The orbits partition X, and $gG_xg^{-1} = G_{gx}$.

Proposition 20.3.2. *Let G act on X, with $\pi \colon X \to X/G$.*

1. *π is open: for U open, $\pi^{-1}(\pi(U)) = \bigcup_{g \in G} gU$ is open.*

2. *X/G is Hausdorff if and only if the* orbit relation $R = \{(x, gx) : x \in X, g \in G\}$ *is closed in $X \times X$.*

3. *If X is second countable, so is X/G; if X is compact, connected or path-connected, so is X/G.*

4. *If G is compact and X Hausdorff, then X/G is Hausdorff, π is closed, and for each x the map $G/G_x \to Gx$, $gG_x \mapsto gx$, is a homeomorphism.*

Proof. (1) Each gU is open. (2) Suppose R is closed and $\pi(x) \neq \pi(y)$. Then $(x, y) \notin R$, so there are open $U \ni x$ and $V \ni y$ with $(U \times V) \cap R = \emptyset$. The sets $\pi(U)$ and $\pi(V)$ are open by (1) and disjoint: if $\pi(u) = \pi(v)$ then $(u, v) \in R$. Conversely, if X/G is Hausdorff, its diagonal is closed (a point (a, b) with $a \neq b$ has the neighbourhood $A \times B$, for disjoint neighbourhoods $A \ni a$, $B \ni b$, which misses the diagonal), and R is its preimage under the continuous map $\pi \times \pi$. (3) The images of a countable basis form a countable basis, since π is open, continuous and surjective; continuous images of compact, connected or path-connected spaces have the same property.

(4) We first show that projections along a compact factor are closed: if K is compact, Y any space and $C \subseteq K \times Y$ closed, then $\mathrm{pr}_Y(C)$ is closed. Indeed, if $y \notin \mathrm{pr}_Y(C)$, each $k \in K$ has a product neighbourhood $A_k \times B_k$ of (k, y) disjoint from C; finitely many $A_{k_1}, \ldots, A_{k_r}$ cover K, and $B = \bigcap_j B_{k_j}$ is a neighbourhood of y with $(K \times B) \cap C = \emptyset$, so B misses $\mathrm{pr}_Y(C)$. Now let $C \subseteq X$ be closed. Then $\pi^{-1}(\pi(C)) = GC$ is the projection to X of $\{(g, x) : g^{-1}x \in C\}$, which is closed in $G \times X$; so GC is closed, and π is a closed map. Next, as X is Hausdorff its diagonal Δ_X is closed (as in (2)), and R is the projection to $X \times X$ of the closed set $\{(g, x, y) : (gx, y) \in \Delta_X\} \subseteq G \times X \times X$; so R is closed and X/G is Hausdorff by (2). Finally $g \mapsto gx$ induces a continuous bijection from G/G_x, which is compact as the image of G, to the Hausdorff space Gx; it is a homeomorphism by Proposition 18.6.3(4). □

For the trivial group $G = \{e\}$, $X/G = X$ and the orbit relation is the diagonal $\Delta_X = \{(x, x)\}$, so (2) says: *X is Hausdorff if and only if the diagonal is closed in $X \times X$*. This is the most useful form of the Hausdorff property: for instance, if $f, g \colon Z \to X$ are continuous and X is Hausdorff, the set $\{z : f(z) = g(z)\}$, the preimage of Δ_X under (f, g), is closed.

Example 20.3.3.

1. $\mathbb{Z}$ acts on $\mathbb{R}$ by translations. The map $t \mapsto e^{2\pi it}$ induces a continuous bijection $\mathbb{R}/\mathbb{Z} \to S^1$, which is a homeomorphism because $\mathbb{R}/\mathbb{Z}$ is compact, the image of $[0, 1]$. Likewise $\mathbb{R}^n/\mathbb{Z}^n \cong (S^1)^n = T^n$, the n-torus.

2. $\{\pm 1\}$ acts on S^n by $x \mapsto \pm x$, and $S^n/\{\pm 1\} = \mathbb{RP}^n$, the real projective space.

3. $\mathbb{R}^\times$ acts on $\mathbb{R}^{n+1} \setminus \{0\}$ by scalar multiplication, and the orbit space is again $\mathbb{RP}^n$; $\mathbb{C}^\times$ acting on $\mathbb{C}^{n+1} \setminus \{0\}$ gives the complex projective space $\mathbb{CP}^n$, and S^1 acting on $S^{2n+1} \subseteq \mathbb{C}^{n+1}$ gives $\mathbb{CP}^n$ as well (Proposition 20.6.3).

4. $\mathrm{O}(n)$ acts transitively on S^{n-1}, with the stabiliser of e_n equal to $\mathrm{O}(n-1)$ (embedded in the upper left corner). By Proposition 20.3.2(4), $S^{n-1} \cong \mathrm{O}(n)/\mathrm{O}(n-1)$; similarly $S^{2n-1} \cong \mathrm{U}(n)/\mathrm{U}(n-1)$.

Lemma 20.3.4 (Kronecker)**.** *If $\alpha \in \mathbb{R}$ is irrational, the set $\{n\alpha - \lfloor n\alpha \rfloor : n \in \mathbb{Z}\}$ of fractional parts is dense in $[0, 1]$.*

Proof. Let $N \geq 1$. The $N + 1$ fractional parts of $0, \alpha, \ldots, N\alpha$ lie in $[0, 1)$, which is the union of the N intervals $[j/N, (j+1)/N)$, so two of them, of $k\alpha$ and $l\alpha$ with $k < l$, lie in the same interval. Then $m = l - k$ satisfies $0 < |m\alpha - p| < 1/N$ for some integer p; the first inequality holds because α is irrational. Replacing m, p by $-m$, $-p$ if necessary, we may assume that $\beta = m\alpha - p$ satisfies $0 < \beta < 1/N$. The numbers $j\beta$, $j = 0, 1, 2, \ldots$, increase in steps of $\beta < 1/N$, so every interval $[c, c + 1/N) \subseteq [0, 1)$ contains some $j\beta$; and for $0 \leq j\beta < 1$, $j\beta = (jm)\alpha - jp$ is the fractional part of $(jm)\alpha$. As N is arbitrary, the set is dense. □

Counterexample 20.3.5. Orbit spaces can be very bad. Let α be irrational and let $\mathbb{Z}$ act on S^1 by $n \cdot z = e^{2\pi i n\alpha} z$. By Lemma 20.3.4 every orbit is dense. If $U \subseteq S^1$ is open, saturated and

nonempty, then for every $y \in S^1$ the orbit of y meets U, so $y \in U$; hence $U = S^1$. The orbit space $S^1/\mathbb{Z}$ is therefore an uncountable set with the indiscrete topology: it is not Hausdorff, and every map from it to a Hausdorff space is constant. The action is free.

20.4 Covering space actions and quotients

From now on in this section G is a group acting on X by homeomorphisms, that is, a topological group with the discrete topology.

Definition 20.4.1. An action of a discrete group G on X is

1. a *covering space action* if every $x \in X$ has a neighbourhood U with $gU \cap U = \emptyset$ for all $g \neq e$;
2. *proper* if for every compact $K \subseteq X$ the set $\{g \in G : gK \cap K \neq \emptyset\}$ is finite.

A covering space action is free. An action of a finite group is proper.

Theorem 20.4.2. *Let G act on X by a covering space action. Then $\pi\colon X \to X/G$ is a covering map. If X is path-connected, then π is a normal covering whose deck transformation group is G, and $\pi_1(X/G)/\pi_*\pi_1(X) \cong G$; in particular $\pi_1(X/G) \cong G$ if X is simply connected.*

Proof. Let $x \in X$ and U as in Definition 20.4.1. Then $\pi^{-1}(\pi(U)) = \bigsqcup_{g\in G} gU$, a disjoint union of open sets: if $gU \cap hU \neq \emptyset$ then $h^{-1}gU \cap U \neq \emptyset$, so $g = h$. The restriction of π to gU is continuous, open (Proposition 20.3.2(1)) and injective, since $\pi(gu) = \pi(gu')$ means $gu' = hgu$ for some h, whence $g^{-1}hg = e$ and $u = u'$. So $\pi|_{gU}$ is a homeomorphism onto the open set $\pi(U)$, and $\pi(U)$ is evenly covered.

Each g is a deck transformation, since $\pi(gx) = \pi(x)$, and G acts transitively on each fibre $\pi^{-1}(\pi(x)) = Gx$. If X is path-connected, a deck transformation is determined by the image of one point (Chapter 19), so every deck transformation τ equals the g with $gx = \tau(x)$, and $g \mapsto (x \mapsto gx)$ is an isomorphism $G \to \mathrm{Deck}(\pi)$, injective because the action is free. The deck group acts transitively on the fibres, so the covering is normal, and Proposition 19.6.3(2) gives $\pi_1(X/G)/\pi_*\pi_1(X) \cong \mathrm{Deck}(\pi) \cong G$. □

Theorem 20.4.3. *Let a discrete group G act freely and properly on a locally compact Hausdorff space X. Then the action is a covering space action and X/G is Hausdorff.*

Proof. Let $x \in X$ and let K be a compact neighbourhood of x (containing an open neighbourhood of x). The set $F = \{g \neq e : gK \cap K \neq \emptyset\}$ is finite. For $g \in F$, $gx \neq x$ as the action is free, so there are disjoint open sets $V_g \ni x$ and $W_g \ni gx$. Let $U = \operatorname{int} K \cap \bigcap_{g\in F}(V_g \cap g^{-1}W_g)$, an open neighbourhood of x. For $g \neq e$ not in F, $gU \cap U \subseteq gK \cap K = \emptyset$; for $g \in F$, $gU \subseteq W_g$ and $U \subseteq V_g$, which are disjoint. So the action is a covering space action.

For the Hausdorff property we show that the orbit relation R is closed (Proposition 20.3.2(2)). Let $(x, y) \notin R$ and choose compact neighbourhoods K_x of x and K_y of y. With $K = K_x \cup K_y$, the set $F = \{g : gK_x \cap K_y \neq \emptyset\}$ is contained in $\{g : gK \cap K \neq \emptyset\}$, hence finite. For $g \in F$, $gx \neq y$, so there are disjoint open $A_g \ni gx$ and $B_g \ni y$. Put $U = \operatorname{int} K_x \cap \bigcap_{g\in F} g^{-1}A_g$ and $V = \operatorname{int} K_y \cap \bigcap_{g\in F} B_g$. For every g, $gU \cap V = \emptyset$: if $g \notin F$ because $gK_x \cap K_y = \emptyset$, and if $g \in F$ because $gU \subseteq A_g$ and $V \subseteq B_g$. Hence $(U \times V) \cap R = \emptyset$. □

Counterexample 20.4.4. A covering space action need not have a Hausdorff quotient. Let $\mathbb{Z}$ act on $X = \mathbb{R}^2 \setminus \{0\}$ by $n \cdot (x, y) = (2^n x, 2^{-n} y)$. It is a covering space action: a point with $x \neq 0$ has the neighbourhood $\{(x', y') : |x|/\sqrt{2} < |x'| < \sqrt{2}|x|\}$, which is moved off itself by every $n \neq 0$, and similarly if $y \neq 0$. But the points $p = (1, 0)$ and $q = (0, 1)$ lie in different orbits,

while $(1, 2^{-k}) \to p$ and $(-k) \cdot (1, 2^{-k}) = (2^{-k}, 1) \to q$; so (p, q) lies in the closure of the orbit relation, which is not closed, and $X/\mathbb{Z}$ is not Hausdorff. The action is free but not proper: the compact set $K = \{(x, y) : \max(|x|, |y|) = 1\}$ meets its translates by all n.

Example 20.4.5.

1. $\mathbb{Z}^n$ acts freely and properly on $\mathbb{R}^n$ by translations; $T^n = \mathbb{R}^n/\mathbb{Z}^n$ and $\pi_1(T^n) \cong \mathbb{Z}^n$, as $\mathbb{R}^n$ is simply connected.
2. $\{\pm 1\}$ acts freely on S^n, so $\pi_1(\mathbb{RP}^n) \cong \mathbb{Z}/2$ for $n \geq 2$, since S^n is simply connected for $n \geq 2$ (Chapter 19).
3. (Lens spaces) Let $p \geq 2$ and q be coprime integers, $\zeta = e^{2\pi i/p}$. The group $\mathbb{Z}/p$ acts freely on $S^3 \subseteq \mathbb{C}^2$ by $k \cdot (z_1, z_2) = (\zeta^k z_1, \zeta^{qk} z_2)$: if $\zeta^k z_1 = z_1$ and $\zeta^{qk} z_2 = z_2$ with $(z_1, z_2) \neq 0$, then $\zeta^k = 1$ or $\zeta^{qk} = 1$, and either forces $p \mid k$ as q is prime to p. The quotient $L(p, q) = S^3/(\mathbb{Z}/p)$ is the *lens space*, with $\pi_1 \cong \mathbb{Z}/p$.
4. (Klein bottle) The transformations $a(x, y) = (x + \frac{1}{2}, -y)$ and $b(x, y) = (x, y + 1)$ of $\mathbb{R}^2$ generate a group G acting freely and properly, with $aba^{-1} = b^{-1}$; the quotient $\mathbb{R}^2/G$ is the Klein bottle, with $\pi_1 \cong G$, a non-abelian group.

20.5 Topological manifolds

Definition 20.5.1. Let $n \geq 0$. A space M is *locally Euclidean of dimension n* if every point has a neighbourhood homeomorphic to an open subset of $\mathbb{R}^n$ (equivalently, to $\mathbb{R}^n$ itself, since every point of an open subset of $\mathbb{R}^n$ has a ball neighbourhood, and balls are homeomorphic to $\mathbb{R}^n$). A *topological manifold of dimension n*, or *n-manifold*, is a space that is

1. locally Euclidean of dimension n,
2. Hausdorff, and
3. second countable.

A *chart* is a homeomorphism $\varphi \colon U \to \varphi(U)$ from an open $U \subseteq M$ onto an open subset of $\mathbb{R}^n$.

That the dimension of a nonempty manifold is determined by the space is a theorem, proved with homology (Chapter 23). The next three counterexamples show that none of the three axioms follows from the other two.

Counterexample 20.5.2 (Not Hausdorff)**.** The *line with two origins* L is the quotient of $\mathbb{R} \times \{1, 2\}$ by $(t, 1) \sim (t, 2)$ for $t \neq 0$ (Counterexample 18.4.12). The quotient map is open, the two copies of $\mathbb{R}$ map homeomorphically onto open subsets covering L, so L is locally Euclidean of dimension 1 and second countable. But the two origins $0_1, 0_2$ have no disjoint neighbourhoods: every neighbourhood of 0_i contains the images of $(-\varepsilon, \varepsilon) \setminus \{0\}$ for some $\varepsilon > 0$. In L the sequence $1/n$ converges to both origins, so limits are not unique.

Counterexample 20.5.3 (Not second countable)**.** Let I be an uncountable set with the discrete topology, and $M = I \times \mathbb{R}$, a disjoint union of uncountably many lines. It is locally Euclidean of dimension 1 and Hausdorff. It is not second countable: a basis must contain, for each $i \in I$, a nonempty open subset of $\{i\} \times \mathbb{R}$, and these are pairwise distinct. Connected examples also exist: the *long line* and the *Prüfer surface* are connected, Hausdorff and locally Euclidean of dimensions 1 and 2 but not second countable [Mun00]. Without second countability, partitions of unity (Theorem 18.10.6) and embeddings in $\mathbb{R}^N$ can fail.

Lemma 20.5.4. *Let $n \geq 2$, $W \subseteq \mathbb{R}^n$ open and connected, and $p \in W$. Then $W \setminus \{p\}$ is connected. For $n = 1$, removing a point from an open interval leaves exactly two components.*

Proof. $\mathbb{R}^n \setminus \{0\}$ is path-connected for $n \geq 2$: two points a, b are joined by the segment $[a, b]$ unless 0 lies on it, and then by the segments $[a, c]$ and $[c, b]$ for any c not on the line through a and b. Hence every punctured ball $B \setminus \{p\}$, homeomorphic to $\mathbb{R}^n \setminus \{0\}$, is path-connected. Choose a ball B with $p \in B \subseteq W$ and let A be the set of points of $W \setminus \{p\}$ that can be joined to a point of $B \setminus \{p\}$ by a path in $W \setminus \{p\}$. Every point of $W \setminus \{p\}$ has a ball neighbourhood in $W \setminus \{p\}$, which is path-connected; so A and its complement in $W \setminus \{p\}$ are open. If the complement were nonempty, then $W = (A \cup B) \cup (W \setminus (A \cup \{p\}))$ would be a decomposition into disjoint nonempty open sets ($A \cup B$ is open, and $B \setminus \{p\} \subseteq A$), contradicting connectedness. So $W \setminus \{p\} = A$ is path-connected. The case $n = 1$ is clear, as connected subsets of $\mathbb{R}$ are intervals (Theorem 18.5.3). □

Counterexample 20.5.5 (Not locally Euclidean)**.** The union $X = \{(x, y) \in \mathbb{R}^2 : xy = 0\}$ of the two coordinate axes is Hausdorff and second countable, being a subspace of $\mathbb{R}^2$, but not locally Euclidean at the origin. Suppose $\varphi \colon U \to \varphi(U) \subseteq \mathbb{R}^n$ were a chart at 0. Choose $\varepsilon > 0$ with $V = X \cap (-\varepsilon, \varepsilon)^2 \subseteq U$. Then V is a cross with four open arms, open in X and connected, and $V \setminus \{0\}$ has exactly four components, the arms. So $W = \varphi(V)$ is a connected open subset of $\mathbb{R}^n$, and $W \setminus \{\varphi(0)\}$, homeomorphic to $V \setminus \{0\}$, has four components. This contradicts Lemma 20.5.4 for $n \geq 1$, and $n = 0$ is impossible because $\{0\}$ is not open in X.

Similarly the closed half-line $[0, +\infty)$ is not locally Euclidean at 0. If φ were a chart at 0 with values in $\mathbb{R}^n$: $n = 0$ is impossible as before; for $n = 1$, a connected neighbourhood $[0, \varepsilon) \subseteq U$ would map to an open interval, which is disconnected by removing the image of 0, while $(0, \varepsilon)$ is connected; for $n \geq 2$, a small interval $J \subseteq (0, \varepsilon)$ would map to a connected open subset of $\mathbb{R}^n$ that stays connected after removing a point, while J does not. It is a manifold with boundary (Definition 20.5.11).

Proposition 20.5.6. *Let M be an n-manifold.*

1. *M is locally compact and locally path-connected. Its connected components are open, coincide with its path components, and are countable in number.*
2. *Every open subset of M is an n-manifold.*
3. *M is paracompact and admits partitions of unity subordinate to any open cover.*
4. *M has a countable cover by open sets B_i with homeomorphisms $B_i \cong \mathbb{R}^n$ (*coordinate balls*).*

Proof. (1) Each point has a neighbourhood homeomorphic to $\mathbb{R}^n$, and closed balls and open balls in $\mathbb{R}^n$ give compact and path-connected neighbourhoods. In a locally path-connected space, path components are open, hence also closed, and so they are the components. They are disjoint open sets, each containing an element of a countable basis, so there are countably many. (2) The three axioms pass to open subspaces. (3) By (1) and Hausdorffness M is locally compact Hausdorff and second countable, so Proposition 18.10.7 and Theorem 18.10.6 apply. (4) Let $\mathcal{B}$ be a countable basis and $\mathcal{B}'$ the set of $W \in \mathcal{B}$ contained in the domain of some chart; for each $W \in \mathcal{B}'$ fix a chart φ_W whose domain contains W. The sets $\varphi_W^{-1}(B)$, for $W \in \mathcal{B}'$ and B an open ball with rational centre and radius contained in $\varphi_W(W)$, are countably many coordinate balls. They cover M: a point x lies in a chart domain, hence in some $W \in \mathcal{B}$ inside it, so $W \in \mathcal{B}'$, and $\varphi_W(x)$ lies in a rational ball contained in the open set $\varphi_W(W)$. □

Corollary 20.5.7. *Every topological manifold is metrisable: its topology is induced by a metric.*

Proof. By Proposition 20.5.6(3), M is paracompact and Hausdorff, hence normal (Proposition 18.10.3). Points of a Hausdorff space are closed, so given a closed set A and a point $x \notin A$, normality separates the disjoint closed sets $\{x\}$ and A by disjoint open sets: M is regular. Being also second countable, it is metrisable by the Urysohn metrisation theorem (Theorem 18.8.8). □

Remark 20.5.8. 1. The metric is not canonical, and the proof does not produce a useful one. On a smooth manifold there are better choices, with the same topology: the restriction of the Euclidean distance under an embedding in some $\mathbb{R}^N$ (Whitney's theorem, Chapter 33), or the distance of a Riemannian metric (Chapter 40).

2. *Which axioms are needed?* A metrisable space is Hausdorff, so the line with two origins (Counterexample 20.5.2) is not metrisable. The disjoint union of uncountably many lines (Counterexample 20.5.3) is metrisable, with the metric $\min(|s-t|, 1)$ between points s, t of the same line and 1 between points of different lines, but not second countable. The connected examples are not metrisable: for a connected, Hausdorff, locally Euclidean space, being metrisable, being paracompact and being second countable are equivalent [Spi99, Appendix A]. For the long line one sees it directly: every sequence lies in a compact subset homeomorphic to a closed interval, so the long line is sequentially compact, but it is not compact, while for metric spaces the two notions coincide.

Theorem 20.5.9. *The fundamental group of a connected manifold is countable.*

Proof. Let $\{B_i\}$ be a countable cover of M by coordinate balls (Proposition 20.5.6(4)); each B_i is simply connected, being homeomorphic to $\mathbb{R}^n$. For each pair i, j, the open set $B_i \cap B_j$ has countably many path components (by Proposition 20.5.6(1)); choose a point in each, and let S be the countable set of all chosen points, together with a base point p. For any two points $s, s' \in S$ lying in a common B_i, choose a path $\sigma^i_{s,s'}$ in B_i from s to s'; these are countably many paths. We claim that every loop γ at p is homotopic to a finite concatenation of such paths; since there are countably many finite concatenations, this proves the theorem.

By the Lebesgue number lemma there is a partition $0 = t_0 < t_1 < \cdots < t_k = 1$ with $\gamma([t_{m-1}, t_m]) \subseteq B_{i_m}$. We may take $p \in B_{i_1} \cap B_{i_k}$. For $0 < m < k$, the point $\gamma(t_m)$ lies in $B_{i_m} \cap B_{i_{m+1}}$, in a path component containing some $s_m \in S$; choose a path τ_m in that component from $\gamma(t_m)$ to s_m, and let τ_0, τ_k be constant at $p = s_0 = s_k$. Then γ is homotopic to the concatenation over m of the paths $\bar{\tau}_{m-1} \cdot \gamma|_{[t_{m-1},t_m]} \cdot \tau_m$, each of which runs in B_{i_m} from s_{m-1} to s_m. As B_{i_m} is simply connected, each is homotopic relative to its endpoints to $\sigma^{i_m}_{s_{m-1},s_m}$. □

Corollary 20.5.10. *If M is a connected n-manifold and $p : E \to M$ a covering map with E connected, then E is an n-manifold.*

Proof. E is locally homeomorphic to M, hence locally Euclidean. It is Hausdorff: two points in different fibres are separated by preimages of disjoint neighbourhoods in M, and two points in the same fibre lie in different sheets over an evenly covered neighbourhood. The fibres are in bijection with the cosets of $p_*\pi_1(E)$ in the countable group $\pi_1(M)$ (Chapter 19), hence countable. If $\{W_k\}$ is a countable basis of M consisting of evenly covered sets, then the sheets over the W_k form a countable family of open sets, and the sheets over basic open subsets of the W_k give a countable basis of E. □

If M is a smooth manifold, E has a unique smooth structure for which p is a local diffeomorphism, obtained by composing the charts of M with the local inverses of p (Chapter 33); this is how $S^n \to \mathbb{RP}^n$, $\mathbb{R}^n \to T^n$ and universal coverings of smooth manifolds are treated as smooth maps.

Definition 20.5.11. Let $\mathbb{H}^n = \{x \in \mathbb{R}^n : x_n \geq 0\}$. An *$n$-manifold with boundary* is a Hausdorff, second countable space in which every point has a neighbourhood homeomorphic to an open subset of $\mathbb{H}^n$. A point is an *interior point* if it has a neighbourhood homeomorphic to $\mathbb{R}^n$, and a *boundary point* otherwise; the boundary is written ∂M.

A point sent by a chart to a point with $x_n > 0$ is interior. That a point sent by some chart to $\{x_n = 0\}$ is not interior, so that ∂M is the set of such points and ∂M is an $(n-1)$-manifold, uses invariance of domain (Chapter 23); for $n = 1$ it follows from Lemma 20.5.4.

Example 20.5.12. The closed disc D^n is an n-manifold with boundary S^{n-1}; $[0,1]$ has boundary $\{0,1\}$; the *Möbius band*, the quotient of $[0,1]\times[-1,1]$ by $(0,t) \sim (1,-t)$, has boundary a single circle.

20.6 Constructions of manifolds

Proposition 20.6.1. *1. Open subsets of n-manifolds and countable disjoint unions of n-manifolds are n-manifolds.*

2. If M is an m-manifold and N an n-manifold, $M \times N$ is an $(m+n)$-manifold.

3. If a discrete group G acts freely and properly on an n-manifold M, then M/G is an n-manifold, and $M \to M/G$ is a covering map.

4. Connected covering spaces of connected n-manifolds are n-manifolds.

Proof. (1) Clear. (2) Products of charts are charts, $\mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$, and products of Hausdorff or second countable spaces are Hausdorff or second countable. (3) By Theorem 20.4.3 and Proposition 20.5.6(1) the quotient is Hausdorff and π is a covering map, so M/G is locally homeomorphic to M; it is second countable by Proposition 20.3.2(3). (4) is Corollary 20.5.10. □

Example 20.6.2. 1. $\mathbb{R}^n$; open subsets such as $\mathrm{GL}_n(\mathbb{R}) \subseteq \mathbb{R}^{n^2}$.

2. The sphere $S^n \subseteq \mathbb{R}^{n+1}$, with the two stereographic charts (Example 18.9.4); it is Hausdorff and second countable as a subspace of $\mathbb{R}^{n+1}$.

3. The graph $\{(x, f(x))\}$ of a continuous map $f : U \to \mathbb{R}^k$, $U \subseteq \mathbb{R}^n$ open, is an n-manifold, homeomorphic to U by the projection.

4. The torus $T^n = \mathbb{R}^n/\mathbb{Z}^n$, $\mathbb{RP}^n = S^n/\{\pm 1\}$, the lens spaces and the Klein bottle of Example 20.4.5, by Proposition 20.6.1(3).

Proposition 20.6.3. *$\mathbb{CP}^n = (\mathbb{C}^{n+1} \setminus \{0\})/\mathbb{C}^\times$ is a compact $2n$-manifold, homeomorphic to S^{2n+1}/S^1. The sets $U_i = \{[z] : z_i \neq 0\}$ are open and $\varphi_i([z]) = (z_0/z_i, \dots, \widehat{z_i/z_i}, \dots, z_n/z_i)$ is a homeomorphism $U_i \to \mathbb{C}^n$. The same holds for $\mathbb{RP}^n$, with $\mathbb{R}$ in place of $\mathbb{C}$.*

Proof. The inclusion $S^{2n+1} \to \mathbb{C}^{n+1} \setminus \{0\}$ induces a continuous map $S^{2n+1}/S^1 \to \mathbb{CP}^n$, which is bijective since every line meets the sphere in a circle, and has continuous inverse induced by $z \mapsto z/|z|$. By Proposition 20.3.2(3),(4) applied to the compact group S^1, $\mathbb{CP}^n$ is compact, Hausdorff and second countable. The set U_i is open because its preimage $\{z_i \neq 0\}$ is. The map φ_i is well defined and continuous (it is induced by a continuous map constant on orbits), with continuous inverse $w \mapsto [w_0 : \cdots : 1 : \cdots : w_n]$, the 1 in position i. □

Example 20.6.4. $\mathbb{CP}^1$ is homeomorphic to S^2, by an explicit map. Identify $\mathbb{R}^3$ with $\mathbb{C}\times\mathbb{R}$ and let

$$h : \mathbb{CP}^1 \to S^2, \qquad h([z_0 : z_1]) = \frac{(2\bar{z}_0 z_1,\ |z_1|^2 - |z_0|^2)}{|z_0|^2 + |z_1|^2}.$$

Multiplying (z_0, z_1) by $\lambda \in \mathbb{C}^\times$ multiplies numerator and denominator by $|\lambda|^2$, so h is well defined, and it is continuous since it is induced by a continuous map on $\mathbb{C}^2 \setminus \{0\}$. It takes

values in S^2, because $|2\bar{z}_0 z_1|^2 + (|z_1|^2 - |z_0|^2)^2 = (|z_0|^2 + |z_1|^2)^2$. In the chart $U_0 = \{z_0 \neq 0\}$, with $w = z_1/z_0$,

$$h([1 : w]) = \frac{(2w,\ |w|^2 - 1)}{|w|^2 + 1},$$

which is the inverse of the stereographic projection from $N = (0, 1)$ (Example 18.9.4, with $\mathbb{R}^2 = \mathbb{C}$). So h maps U_0 bijectively onto $S^2 \setminus \{N\}$, and the remaining point $[0 : 1]$ goes to N. Thus h is a continuous bijection from the compact space $\mathbb{CP}^1$ to the Hausdorff space S^2, hence a homeomorphism: $\mathbb{CP}^1$ is the one-point compactification of the chart $U_0 \cong \mathbb{C}$, the *Riemann sphere*. The composite $S^3 \to \mathbb{CP}^1 \to S^2$, $(z_0, z_1) \mapsto (2\bar{z}_0 z_1, |z_1|^2 - |z_0|^2)$, is the Hopf map of Remark 19.8.8. For $\mathbb{RP}^1$ the same construction gives $\mathbb{RP}^1 \cong S^1$, the one-point compactification of $\mathbb{R}$.

20.7 Hopf fibrations

The quotient map $S^{2n+1} \to \mathbb{CP}^n$ of Proposition 20.6.3 has all its fibres equal to circles, and near each point it looks like a product. Replacing $\mathbb{C}$ by $\mathbb{R}$ or by the quaternions gives a whole family of such maps, the *Hopf fibrations*: $S^n \to \mathbb{RP}^n$ with fibre S^0, $S^{2n+1} \to \mathbb{CP}^n$ with fibre S^1, and $S^{4n+3} \to \mathbb{HP}^n$ with fibre S^3. For $n = 1$ the base is a sphere, and one gets the maps $S^1 \to S^1$, $S^3 \to S^2$ and $S^7 \to S^4$, to which the octonions add $S^{15} \to S^8$. They are the first nontrivial examples of fibre bundles, and through the long exact sequence of homotopy groups they show that a sphere can have nonzero homotopy groups above its dimension.

Definition 20.7.1. A *fibre bundle* with fibre F is a continuous map $p\colon E \to B$ such that every point of B has an open neighbourhood U with a homeomorphism $\phi\colon U \times F \to p^{-1}(U)$ satisfying $p \circ \phi = \mathrm{pr}_U$, a *local trivialisation*.

A covering space is a fibre bundle with discrete fibre, and a vector bundle (Chapter 35) is a fibre bundle with fibre a vector space and linear transition maps.

Theorem 20.7.2. *A fibre bundle $p\colon E \to B$ is a Serre fibration (Definition 19.8.4). Hence, for B path-connected and $F = p^{-1}(b_0)$, there is a long exact sequence $\cdots \to \pi_k(F) \to \pi_k(E) \to \pi_k(B) \to \pi_{k-1}(F) \to \cdots$ (Theorem 19.8.5(2)).*

This is [Hat02, Proposition 4.48]: the homotopy lifting property for cubes is local on the base, as for coverings, and over a set U where E is trivial a homotopy into $U \times F$ is lifted by keeping the F-component of the initial lift constant; the work lies in subdividing the cube so that each piece maps into a trivialising set.

Let $\mathbb{K}$ be $\mathbb{R}$, $\mathbb{C}$ or the quaternions $\mathbb{H}$ (Example 8.2.3), of real dimension $d = 1, 2$ or 4. Each has a conjugation $\lambda \mapsto \bar{\lambda}$ and the multiplicative norm $|\lambda| = (\lambda\bar{\lambda})^{1/2}$; for $\mathbb{H}$, viewed as matrices $\left(\begin{smallmatrix} z & -\bar{w} \\ w & \bar{z} \end{smallmatrix}\right)$, $\bar{\lambda}$ is the conjugate transpose and $|\lambda|^2$ is the determinant $|z|^2 + |w|^2$, so $|\lambda\mu| = |\lambda||\mu|$, and $\mathbb{H} \cong \mathbb{R}^4$ isometrically. The unit elements form the group S^{d-1}: $S^0 = \{\pm 1\}$, S^1, and $S^3 = \mathrm{SU}(2)$. On $\mathbb{K}^{n+1}$, with the norm $|q|^2 = \sum_i |q_i|^2$, the group $\mathbb{K}^\times$ acts by multiplication on the right, $q \mapsto q\lambda = (q_0\lambda, \ldots, q_n\lambda)$, preserving lines, and $|q\lambda| = |q||\lambda|$. The *projective space*

$$\mathbb{KP}^n = (\mathbb{K}^{n+1} \setminus \{0\})/\mathbb{K}^\times$$

is the set of right $\mathbb{K}$-lines in $\mathbb{K}^{n+1}$; we write $[q] = [q_0 : \cdots : q_n]$. For $\mathbb{K} = \mathbb{H}$, which is not commutative, the side matters: right lines are preserved by left multiplication by matrices, and coordinates $q_j q_i^{-1}$ are invariant under $q \mapsto q\lambda$.

Proposition 20.7.3 (Hopf fibrations)**.** *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$, of real dimension d, and $N = d(n+1) - 1$, so that S^N is the unit sphere of $\mathbb{K}^{n+1}$.*

1. *$\mathbb{KP}^n$ is a compact manifold of dimension dn, homeomorphic to S^N/S^{d-1}, with the charts $\varphi_i\colon U_i = \{[q] : q_i \neq 0\} \to \mathbb{K}^n$, $\varphi_i([q]) = (q_0 q_i^{-1}, \dots, \widehat{q_i q_i^{-1}}, \dots, q_n q_i^{-1})$.*

2. *The projection $p\colon S^N \to \mathbb{KP}^n$, $p(q) = [q]$, is a fibre bundle with fibre S^{d-1}: over U_i the map $\phi_i\colon U_i \times S^{d-1} \to p^{-1}(U_i)$, $\phi_i([q], \lambda) = \sigma_i([q])\lambda$ with $\sigma_i([q]) = q\, q_i^{-1}|q_i|/|q|$, is a local trivialisation.*

Proof. (1) The proof of Proposition 20.6.3 applies word for word. Every right line meets S^N in an orbit qS^{d-1}, so $S^N/S^{d-1} \to \mathbb{KP}^n$ is a continuous bijection with continuous inverse induced by $q \mapsto q/|q|$, and $\mathbb{KP}^n$ is compact, Hausdorff and second countable as the orbit space of a compact group (Proposition 20.3.2). The map φ_i is well defined, as $(q_j\lambda)(q_i\lambda)^{-1} = q_j\lambda\lambda^{-1}q_i^{-1} = q_j q_i^{-1}$, continuous, and has the continuous inverse $w \mapsto [w_0 : \cdots : 1 : \cdots : w_n]$ with 1 in position i.

(2) The map σ_i is well defined on U_i: replacing q by $q\mu$ replaces $q q_i^{-1}$ by $q\mu\mu^{-1}q_i^{-1} = q q_i^{-1}$ and does not change $|q_i|/|q|$. Its value is the unique unit vector of the line $[q]$ whose i-th coordinate is a positive real number, namely $|q_i|/|q|$; in particular $|\sigma_i([q])| = 1$ and $p \circ \sigma_i = \mathrm{id}$, so $p(\phi_i([q], \lambda)) = [q]$. The map ϕ_i is continuous, and it has the continuous inverse $x \mapsto ([x], |x_i|^{-1}x_i)$ on $p^{-1}(U_i)$: for $x \in S^N$ with $x_i \neq 0$, $\sigma_i([x]) = x\, x_i^{-1}|x_i|$, so $\sigma_i([x])\,|x_i|^{-1}x_i = x$, and conversely the i-th coordinate of $\sigma_i([q])\lambda$ is $\frac{|q_i|}{|q|}\lambda$, which recovers λ by normalising. □

Proposition 20.7.4. *$\mathbb{HP}^1$ is homeomorphic to S^4, by $h([q_0 : q_1]) = \big(2q_0\bar{q}_1, |q_0|^2 - |q_1|^2\big)/(|q_0|^2 + |q_1|^2) \in \mathbb{H} \times \mathbb{R} = \mathbb{R}^5$. So the Hopf fibration for $\mathbb{H}$ and $n = 1$ is a fibre bundle $S^7 \to S^4$ with fibre S^3, and for $\mathbb{C}$ it is $S^3 \to S^2$ with fibre S^1 (Example 20.6.4).*

Proof. Replacing (q_0, q_1) by $(q_0\lambda, q_1\lambda)$ multiplies $q_0\bar{q}_1$ by $\lambda\bar{\lambda} = |\lambda|^2$ (as $\overline{q_1\lambda} = \bar{\lambda}\bar{q}_1$) and the denominator by $|\lambda|^2$, so h is well defined, and it is continuous. It takes values in S^4, since $|2q_0\bar{q}_1|^2 + (|q_0|^2 - |q_1|^2)^2 = (|q_0|^2 + |q_1|^2)^2$ by multiplicativity of the norm. On $U_1 = \{q_1 \neq 0\}$, with $w = q_0 q_1^{-1}$, $[q_0 : q_1] = [w : 1]$ and $h([w : 1]) = (2w, |w|^2 - 1)/(|w|^2 + 1)$, the inverse of the stereographic projection $S^4 \setminus \{N\} \to \mathbb{R}^4 = \mathbb{H}$ from $N = (0, 1)$ (Example 18.9.4). So h maps U_1 bijectively onto $S^4 \setminus \{N\}$, and the remaining point $[1 : 0]$ to N. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism. □

For the real numbers the Hopf fibration $S^n \to \mathbb{RP}^n$ is the two-sheeted covering of Example 20.4.5, and for $n = 1$, with $\mathbb{RP}^1 \cong S^1$, it is the map $z \mapsto z^2$ of the circle. The octonions, an eight-dimensional normed algebra that is not associative, give in the same way a fibre bundle $S^{15} \to S^8$ with fibre S^7 [Hat02, Section 4.2].

Corollary 20.7.5. 1. *$\pi_1(\mathbb{CP}^n) = 0$, $\pi_2(\mathbb{CP}^n) \cong \mathbb{Z}$, and $\pi_k(\mathbb{CP}^n) \cong \pi_k(S^{2n+1})$ for $k \geq 3$. In particular $\pi_k(S^2) \cong \pi_k(S^3)$ for $k \geq 3$, so $\pi_3(S^2) \cong \pi_3(S^3)$.*

2. *$\pi_k(\mathbb{HP}^n) \cong \pi_{k-1}(S^3)$ for $k \leq 4n + 2$; in particular $\mathbb{HP}^n$ is 3-connected, $\pi_4(\mathbb{HP}^n) \cong \pi_3(S^3)$, and $\pi_k(S^4) \cong \pi_{k-1}(S^3)$ for $k \leq 6$.*

3. *The map $\pi_7(S^7) \to \pi_7(S^4)$ induced by the Hopf fibration is injective.*

Proof. We use the long exact sequences of Theorem 20.7.2, together with $\pi_k(S^m) = 0$ for $k < m$ (cellular approximation, Theorem 19.7.5, as in Remark 19.8.8), $\pi_1(S^1) \cong \mathbb{Z}$ and $\pi_k(S^1) = 0$ for $k \geq 2$ (Proposition 19.8.3). (1) For $S^1 \to S^{2n+1} \to \mathbb{CP}^n$ with $n \geq 1$, the segment $\pi_k(S^1) \to \pi_k(S^{2n+1}) \to \pi_k(\mathbb{CP}^n) \to \pi_{k-1}(S^1)$ has outer terms 0 for $k \geq 3$. For $k = 2$, $\pi_2(S^{2n+1}) = 0 \to \pi_2(\mathbb{CP}^n) \to \pi_1(S^1) \to \pi_1(S^{2n+1}) = 0$, and for $k = 1$, $0 = \pi_1(S^{2n+1}) \to \pi_1(\mathbb{CP}^n) \to \pi_0(S^1) = 0$. Take $n = 1$ and $\mathbb{CP}^1 \cong S^2$ for the last statement. (2) For $S^3 \to S^{4n+3} \to \mathbb{HP}^n$, if $k \leq 4n + 2$ the groups $\pi_k(S^{4n+3})$ and $\pi_{k-1}(S^{4n+3})$ vanish, so $\pi_k(\mathbb{HP}^n) \to \pi_{k-1}(S^3)$ is an isomorphism; and $\pi_{k-1}(S^3) = 0$ for $k \leq 3$. Take $n = 1$ and

$\mathbb{HP}^1 \cong S^4$ for the last statement. (3) In the segment $\pi_7(S^3) \to \pi_7(S^7) \to \pi_7(S^4)$, the first map is induced by the inclusion of a fibre $S^3 \to S^7$, which is not surjective; as S^7 minus a point is homeomorphic to $\mathbb{R}^7$, which is contractible, the inclusion is null-homotopic and induces 0. By exactness the second map is injective. □

By the Hurewicz theorem (Chapter 21), $\pi_n(S^n) \cong \mathbb{Z}$, so the corollary gives $\pi_3(S^2) \cong \mathbb{Z}$, generated by the Hopf map itself, $\pi_4(S^4) \cong \mathbb{Z}$, and a copy of $\mathbb{Z}$ in $\pi_7(S^4)$: unlike homology, the homotopy groups of a sphere do not vanish above its dimension. The Hopf maps $S^3 \to S^2$, $S^7 \to S^4$ and $S^{15} \to S^8$ are also the maps of Hopf invariant one (Chapter 24), whose mapping cones are the projective planes $\mathbb{CP}^2$, $\mathbb{HP}^2$ and the octonionic plane. Geometrically, the fibres of $S^3 \to S^2$ are great circles, the intersections of S^3 with the complex lines of $\mathbb{C}^2$; any two of them are linked, and the preimages of the two closed hemispheres are the solid tori $\{|z_0| \le |z_1|\}$ and $\{|z_0| \ge |z_1|\}$, which decompose S^3 (Exercise 20.9.5). The bundle $S^{2n+1} \to \mathbb{CP}^n$ is the unit circle bundle of the tautological line bundle $O(-1)$, whose nonzero first Chern class shows again that it is not trivial (Chapters 35 and 39).

20.8 Gluing

Lemma 20.8.1. *Let X and Y be spaces, $U \subseteq X$ and $V \subseteq Y$ open, and $f : U \to V$ a homeomorphism. Let $Z = X \cup_f Y$ be the quotient of $X \sqcup Y$ by $u \sim f(u)$ for $u \in U$.*

1. *X and Y map homeomorphically onto open subsets of Z covering Z.*
2. *If X and Y are Hausdorff, then Z is Hausdorff if and only if the graph $\Gamma_f = \{(u, f(u))\}$ is closed in $X \times Y$.*
3. *If X and Y are n-manifolds and Γ_f is closed, then Z is an n-manifold.*

Proof. (1) The saturation of an open $A \subseteq X$ is $A \sqcup f(A \cap U)$, which is open, so the quotient map q is open, and it is injective on X and on Y. (2) Two points of Z coming from X are separated by images of disjoint open subsets of X, and similarly for Y. The remaining case is $q(x) \ne q(y)$ with $x \in X \setminus U$, $y \in Y \setminus V$; then $(x, y) \notin \Gamma_f$. If Γ_f is closed, there are open $A \ni x$, $B \ni y$ with $(A \times B) \cap \Gamma_f = \emptyset$, that is $f(A \cap U) \cap B = \emptyset$, and $q(A)$, $q(B)$ are disjoint neighbourhoods. Conversely, if $(x, y) \in \bar{\Gamma}_f \setminus \Gamma_f$, then every pair of neighbourhoods $A \ni x$, $B \ni y$ has $f(A \cap U) \cap B \ne \emptyset$, so $q(A) \cap q(B) \ne \emptyset$; and $q(x) \ne q(y)$ (if $x \in U$ then $y \ne f(x)$ since $(x, y) \notin \Gamma_f$; if $x \notin U$ and $y \notin V$ they are not identified; and $x \notin U$, $y \in V$ is also not identified). (3) Locally Euclidean by (1), Hausdorff by (2), and second countable as the union of two open second countable subspaces. □

Counterexample 20.8.2. The line with two origins is $\mathbb{R} \cup_f \mathbb{R}$ with $U = V = \mathbb{R} \setminus \{0\}$ and $f = \mathrm{id}$. The graph of f is the diagonal minus the origin, whose closure in $\mathbb{R} \times \mathbb{R}$ contains $(0, 0)$; in accordance with Lemma 20.8.1(2), the result is not Hausdorff (Counterexample 20.5.2).

Definition 20.8.3. Let M and N be connected n-manifolds, $n \ge 2$, and let $\varphi : U \to \mathbb{R}^n$, $\psi : V \to \mathbb{R}^n$ be charts onto $\mathbb{R}^n$. Let $X = M \setminus \varphi^{-1}(\bar{B}_1)$ and $Y = N \setminus \psi^{-1}(\bar{B}_1)$, where $\bar{B}_r = \{|x| \le r\}$, and let f be the homeomorphism from $\varphi^{-1}(\{1 < |x| < 2\}) \subseteq X$ onto $\psi^{-1}(\{1 < |y| < 2\}) \subseteq Y$ given in coordinates by $x \mapsto (3 - |x|)x/|x|$, which exchanges the two boundary spheres of the annulus. The *connected sum* is $M \# N = X \cup_f Y$.

Proposition 20.8.4. *$M \# N$ is a connected n-manifold, compact if M and N are.*

Proof. X and Y are n-manifolds by Proposition 20.6.1(1). We check that the graph of f is closed in $X \times Y$. Let $(x_k, f(x_k)) \to (x, y) \in X \times Y$ with $1 < |\varphi(x_k)| < 2$; sequences suffice, as

$X \times Y$ is first countable. The points $\varphi(x_k)$ lie in the compact set $\{1 \le |w| \le 2\}$, so a subsequence converges to some w there, and then the corresponding subsequence of (x_k) converges to $\varphi^{-1}(w)$; by uniqueness of limits in the Hausdorff space M, $x = \varphi^{-1}(w)$, and $|w| > 1$ because $x \in X$. In the same way $y = \psi^{-1}(w')$ with $|w'| > 1$ a limit point of $\psi(f(x_k))$, whose norms are $3 - |\varphi(x_k)|$; so $|w'| = 3 - |w|$, which forces $|w| < 2$. Hence x lies in the domain of f, and $y = f(x)$ by continuity of f. By Lemma 20.8.1, $M\#N$ is an n-manifold.

X is connected: the set $E = \varphi^{-1}(\{|w| > 1\})$ is connected, being homeomorphic to $S^{n-1} \times (1, \infty)$ with S^{n-1} path-connected for $n \ge 2$ (as the image of $\mathbb{R}^n \setminus \{0\}$ under $w \mapsto w/|w|$). If $X = A \sqcup A'$ with A, A' open, we may assume $E \subseteq A$; then $M = (A \cup \varphi^{-1}(B_2)) \sqcup A'$ is a decomposition into disjoint open sets, since the points of $\varphi^{-1}(B_2)$ in X lie in E; as M is connected, $A' = \emptyset$. Similarly Y is connected, and the images of X and Y in $M\#N$ meet, so $M\#N$ is connected. If M and N are compact, the closed subsets $M \setminus \varphi^{-1}(B_{3/2}) \subseteq X$ and $N \setminus \psi^{-1}(B_{3/2}) \subseteq Y$ are compact, and their images cover $M\#N$, because a point of X with $1 < |\varphi| < 3/2$ is identified with a point of Y with $3/2 < |\psi| < 2$. □

Remark 20.8.5. The homeomorphism type of $M\#N$ can depend on the choice of charts, through orientations: for orientable manifolds the two choices of relative orientation can give different results. For surfaces, and more generally up to these orientation choices, the result is independent of the charts, but the proof in the topological category uses deep results; in the smooth category it follows from the disc theorem of Palais. We shall only use connected sums of surfaces, where $T^2\#T^2$ is the closed orientable surface of genus 2 and $\mathbb{RP}^2\#\mathbb{RP}^2$ is the Klein bottle.

Theorem 20.8.6 (Classification of surfaces)**.** *Every compact connected* 2*-manifold is homeomorphic to exactly one of: the sphere S^2, a connected sum $T^2\#\cdots\#T^2$ of $g \ge 1$ tori, or a connected sum $\mathbb{RP}^2\#\cdots\#\mathbb{RP}^2$ of $k \ge 1$ projective planes.*

This is [Mun00, Chapter 12]. The surfaces in the list are distinguished by their fundamental groups (their abelianisations are $\mathbb{Z}^{2g}$ and $\mathbb{Z}^{k-1} \oplus \mathbb{Z}/2$), and every compact surface is homeomorphic to one obtained by identifying the edges of a polygon in pairs, which is the route to the proof. In dimension 1 the classification is simpler: every connected 1-manifold is homeomorphic to $\mathbb{R}$ or to S^1 [Mil97, Appendix].

20.9 Exercises

Exercise 20.9.1. Let N be a normal subgroup of a topological group G. Show that G/N with the quotient topology is a topological group, and that it is Hausdorff if and only if N is closed.

Solution. The quotient map $\pi\colon G \to G/N$ is open, by the argument of Proposition 20.3.2(1) for the action of N by right translation. So $\pi \times \pi$ is open and surjective, hence a quotient map, and multiplication $G/N \times G/N \to G/N$ is continuous because its composite with $\pi \times \pi$ is. Inversion is similar. By Proposition 20.2.3(5), G/N is Hausdorff if and only if $\{eN\}$ is closed, that is, if and only if $\pi^{-1}(eN) = N$ is closed (the complement of $\{eN\}$ is open if and only if its preimage $G \setminus N$ is). □

Exercise 20.9.2. Show that a compact Hausdorff space that is locally Euclidean is second countable, hence a manifold.

Solution. Finitely many chart domains $U_1, \ldots, U_k$ cover the space, and each is second countable, being homeomorphic to an open subset of $\mathbb{R}^n$. The union of countable bases of the U_i is a countable basis. □

Exercise 20.9.3. Show that the Möbius band B of Example 20.5.12 is the quotient of $\mathbb{R}\times[-1,1]$ by the free proper action of $\mathbb{Z}$ given by $n\cdot(x,t)=(x+n,(-1)^n t)$, and deduce that $B\setminus\partial B$ is a 2-manifold whose fundamental group is $\mathbb{Z}$.

Solution. Every orbit meets $[0,1]\times[-1,1]$, in one point or, for $x\in\mathbb{Z}$, in the two points $(0,t)$ and $(1,-t)$; the induced continuous bijection from the band to the orbit space is a homeomorphism since the band is compact and the orbit space Hausdorff (Theorem 20.4.3, which applies because $K\cap(K+n)=\emptyset$ for compact K and large $|n|$). Restricted to $\mathbb{R}\times(-1,1)$, which is simply connected and a 2-manifold, Theorem 20.4.2 gives $\pi_1(B\setminus\partial B)\cong\mathbb{Z}$. □

Exercise 20.9.4. Let $\mathbb{Z}$ act on $\mathbb{R}^n\setminus\{0\}$ by $k\cdot x=2^k x$. Show that the action is free and proper, and that the quotient is homeomorphic to $S^{n-1}\times S^1$.

Solution. The map $\mathbb{R}^n\setminus\{0\}\to S^{n-1}\times\mathbb{R}$, $x\mapsto(x/|x|,\log_2|x|)$, is a homeomorphism carrying the action to $k\cdot(u,s)=(u,s+k)$, which is free and proper on $S^{n-1}\times\mathbb{R}$ with quotient $S^{n-1}\times(\mathbb{R}/\mathbb{Z})\cong S^{n-1}\times S^1$ (Example 20.3.3(1)). The action on $S^{n-1}\times\mathbb{R}$ is proper because a compact set lies in some $S^{n-1}\times[-r,r]$, which meets its translate by k only if $|k|\le 2r$. For $n=2$ the quotient is a torus. For $n\ge 3$, $\mathbb{R}^n\setminus\{0\}\cong S^{n-1}\times\mathbb{R}$ is simply connected, S^{n-1} being simply connected (Chapter 19), so the quotient has $\pi_1\cong\mathbb{Z}$ by Theorem 20.4.2. □

Exercise 20.9.5. Let $h\colon S^3\to S^2$, $h(z_0,z_1)=(2\bar z_0 z_1,|z_1|^2-|z_0|^2)$, be the Hopf map (Example 20.6.4). Show that its fibres are the great circles $\{\lambda z:|\lambda|=1\}$, that the fibres over the poles $(0,\pm1)$ are the circles $\{z_0=0\}$ and $\{z_1=0\}$, and that the preimage of the closed upper hemisphere is $\{|z_0|\le|z_1|\}$, which is homeomorphic to the solid torus $D^2\times S^1$. Deduce that S^3 is the union of two solid tori glued along their boundary torus.

Solution. h is the composite of $p\colon S^3\to\mathbb{CP}^1$ with the homeomorphism of Example 20.6.4, so its fibres are those of p, the orbits $\{\lambda z\}$ of S^1; each is the intersection of S^3 with the complex line $\mathbb{C}z$, a real 2-plane through 0, hence a great circle. The last coordinate is 1 exactly when $|z_1|^2-|z_0|^2=1=|z_0|^2+|z_1|^2$, that is $z_0=0$, and -1 exactly when $z_1=0$. It is ≥ 0 exactly when $|z_1|\ge|z_0|$, that is $|z_0|^2\le\frac12$. On this set $z_1\neq 0$, and $(z_0,z_1)\mapsto(\sqrt2\,z_0,z_1/|z_1|)$ is a homeomorphism onto $D^2\times S^1$, with inverse $(a,\mu)\mapsto(a/\sqrt2,\mu(1-|a|^2/2)^{1/2})$. The lower hemisphere gives the solid torus $\{|z_0|\ge|z_1|\}$ in the same way, and the two meet in the torus $|z_0|=|z_1|=1/\sqrt2$, the preimage of the equator. □

Chapter 21

Singular Homology

21.1 Introduction

Singular homology assigns to every space X abelian groups $H_n(X)$, functorial in X and invariant under homotopy. Unlike homotopy groups, they are computable: the long exact sequence of a pair, excision (Theorem 21.5.4) and the Mayer–Vietoris sequence reduce computations to simple pieces, and for CW complexes cellular homology (Theorem 21.7.3) computes them from the cells. The last section compares homology with homotopy groups: H_1 is the abelianised fundamental group, and the first nonvanishing homotopy group of a simply connected space is its first nonvanishing homology group (Theorem 21.9.2). We follow [Hat02, Chapter 2]; see also [Spa66].

Prerequisites. Chapter 19 (Homotopy and Covering Spaces) and Chapter 15 (Homological Algebra).

On the way to the Hodge conjecture. Needed: singular chains, homotopy invariance, relative homology, excision and Mayer–Vietoris, and the homology of spheres (Sections 21.2 to 21.6). Cellular homology is the practical tool for computations; homology with coefficients and the Hurewicz theorems, which compare homology with homotopy groups, can be read when needed.

Abelian groups are written additively. Chain complexes are as in Notation 15.3.2, with differential ∂ of degree -1.

21.2 Singular chains

Definition 21.2.1. The *standard n-simplex* is $\Delta^n = \{(t_0, \dots, t_n) \in \mathbb{R}^{n+1} : t_i \geq 0, \sum_i t_i = 1\}$, with vertices the standard basis vectors $e_0, \dots, e_n$. For points $w_0, \dots, w_k$ of some $\mathbb{R}^N$ we write $[w_0, \dots, w_k] \colon \Delta^k \to \mathbb{R}^N$ for the affine map $(t_i) \mapsto \sum_i t_i w_i$. The *face maps* are $\delta^i = [e_0, \dots, \widehat{e_i}, \dots, e_n] \colon \Delta^{n-1} \to \Delta^n$, where the hat means omission.

Definition 21.2.2. A *singular n-simplex* in a space X is a map $\sigma \colon \Delta^n \to X$. The group $C_n(X)$ of *singular n-chains* is the free abelian group (Definition 7.11.1) with basis the singular n-simplices; its elements are finite formal sums $\sum_i n_i \sigma_i$ with $n_i \in \mathbb{Z}$. For $n < 0$, $C_n(X) = 0$. The *boundary* $\partial \colon C_n(X) \to C_{n-1}(X)$ is the homomorphism with

$$\partial \sigma = \sum_{i=0}^{n} (-1)^i \sigma \circ \delta^i.$$

The *singular homology* of X is $H_n(X) = \ker(\partial \colon C_n \to C_{n-1}) / \operatorname{im}(\partial \colon C_{n+1} \to C_n)$. A map $f \colon X \to Y$ induces $f_\# \colon C_n(X) \to C_n(Y)$, $\sigma \mapsto f \circ \sigma$, and $f_* \colon H_n(X) \to H_n(Y)$.

What the definition says in low dimensions. A singular 0-simplex is a point of X. A singular 1-simplex is a path, via $\Delta^1 \cong I$, $(t_0, t_1) \mapsto t_1$, and $\partial\sigma = \sigma(e_1) - \sigma(e_0)$ is "endpoint minus starting point". A singular 2-simplex σ is a map of a triangle, with three edges $\tau_i = \sigma \circ \delta^i$: τ_2 runs from $\sigma(e_0)$ to $\sigma(e_1)$, τ_0 from $\sigma(e_1)$ to $\sigma(e_2)$, and τ_1 from $\sigma(e_0)$ to $\sigma(e_2)$. So $\partial\sigma = \tau_2 + \tau_0 - \tau_1$ is the boundary of the triangle traversed once: along τ_2, then τ_0, then back along τ_1. The signs in the definition of ∂ are chosen so that this works in every dimension, and so that $\partial\partial = 0$: the boundary of a boundary is empty.

Example 21.2.3.

1. A loop γ, regarded as a 1-simplex, is a cycle: $\partial\gamma = \gamma(1) - \gamma(0) = 0$. More generally, if $f_1, \dots, f_k$ are paths such that each f_i ends where f_{i+1} starts and f_k ends where f_1 starts, then $f_1 + \cdots + f_k$ is a cycle, a "closed polygon" of paths, since the endpoints cancel in pairs.

2. The constant 2-simplex c_2 at a point x has all three edges equal to the constant 1-simplex c_1, so $\partial c_2 = c_1 - c_1 + c_1 = c_1$: a constant path is a boundary, and is zero in $H_1(X)$.

3. The 1-cycles that are boundaries are those that "bound a surface" made of triangles. So $H_1(X)$ counts closed curves in X that are not filled in by surfaces, with multiplicities and signs. In the circle, the cycle formed by the upper and the lower half circle is not a boundary (Example 21.6.2 below), while in a disc every 1-cycle is a boundary (Theorem 21.3.1 below). The precise relation with closed curves up to homotopy is Theorem 21.9.1.

Lemma 21.2.4. *$\partial\partial = 0$, and $f_\#$ is a morphism of chain complexes. Hence H_n is a functor* $\mathsf{Top} \to \mathsf{Ab}$.

Proof. For $i < j$ one has $\delta^j\delta^i = \delta^i\delta^{j-1}$ as maps $\Delta^{n-2} \to \Delta^n$: both are the affine map omitting e_i and e_j. So

$$\partial\partial\sigma = \sum_j \sum_i (-1)^{i+j} \sigma\delta^j\delta^i = \sum_{i<j} (-1)^{i+j} \sigma\delta^i\delta^{j-1} + \sum_{i\geq j} (-1)^{i+j} \sigma\delta^j\delta^i,$$

and substituting $(i, j-1) \mapsto (j', i')$ in the first sum shows that it is the negative of the second. Clearly $\partial f_\# = f_\#\partial$. □

Proposition 21.2.5.

1. *If (X_α) are the path components of X, then $H_n(X) \cong \bigoplus_\alpha H_n(X_\alpha)$.*

2. *If X is path-connected and nonempty, then $H_0(X) \cong \mathbb{Z}$, via $\sum n_i x_i \mapsto \sum n_i$.*

3. *For a point, $H_0 = \mathbb{Z}$ and $H_n = 0$ for $n \neq 0$.*

Proof. (1) The image of a singular simplex is path-connected, so it lies in one X_α, and $C_\bullet(X) = \bigoplus_\alpha C_\bullet(X_\alpha)$ as chain complexes. (2) Singular 0-simplices are points and $\partial\sigma = \sigma(e_1) - \sigma(e_0)$ for a 1-simplex, a path. So the *augmentation* $\varepsilon(\sum n_i x_i) = \sum n_i$ vanishes on boundaries and is surjective. If $\varepsilon(\sum n_i x_i) = 0$, fix x_0 and paths γ_i from x_0 to x_i; then $\sum n_i x_i = \sum n_i(x_i - x_0) = \partial(\sum n_i \gamma_i)$. (3) There is exactly one singular n-simplex σ_n for each n, and $\partial\sigma_n = \sum_{i=0}^n (-1)^i \sigma_{n-1}$ is 0 for n odd and σ_{n-1} for $n \geq 2$ even. So the complex is $\cdots \to \mathbb{Z} \xrightarrow{1} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{1} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \to 0$, with homology $\mathbb{Z}$ in degree 0 only. □

Definition 21.2.6. The *reduced homology* $\tilde{H}_n(X)$ of a nonempty space is the homology of the augmented complex $\cdots \to C_1(X) \to C_0(X) \xrightarrow{\varepsilon} \mathbb{Z} \to 0$, with $\mathbb{Z}$ in degree -1. So $\tilde{H}_n(X) = H_n(X)$ for $n > 0$, $H_0(X) \cong \tilde{H}_0(X) \oplus \mathbb{Z}$, and $\tilde{H}_n(\mathrm{pt}) = 0$ for all n.

21.3 Homotopy invariance

Theorem 21.3.1. *If $f \simeq g\colon X \to Y$, then $f_\#$ and $g_\#$ are chain homotopic, so $f_* = g_*\colon H_n(X) \to H_n(Y)$. Consequently homotopy equivalences induce isomorphisms, and contractible spaces have $\tilde{H}_\bullet = 0$.*

Proof. Let $F\colon X \times I \to Y$ be a homotopy from f to g. In $\Delta^n \times I \subseteq \mathbb{R}^{n+2}$ let $v_i = (e_i, 0)$ and $w_i = (e_i, 1)$. Define the *prism operator* $P\colon C_n(X) \to C_{n+1}(Y)$ by

$$P(\sigma) = \sum_{i=0}^{n} (-1)^i F \circ (\sigma \times \mathrm{id}_I) \circ [v_0, \dots, v_i, w_i, \dots, w_n].$$

Write $[\dots]$ for $F \circ (\sigma \times \mathrm{id}) \circ [\dots]$. Then

$$\partial P(\sigma) = \sum_{j \le i} (-1)^{i+j} [v_0, \dots, \widehat{v_j}, \dots, v_i, w_i, \dots, w_n] + \sum_{j \ge i} (-1)^{i+j+1} [v_0, \dots, v_i, w_i, \dots, \widehat{w_j}, \dots, w_n].$$

In the terms with $i = j$, the term $[v_0, \dots, v_{i-1}, w_i, \dots, w_n]$ of the first sum cancels the term with index $i-1$ of the second sum, for $1 \le i \le n$. What remains of them is $[w_0, \dots, w_n] = g \circ \sigma$ (first sum, $i = 0$) and $-[v_0, \dots, v_n] = -f \circ \sigma$ (second sum, $i = n$). Since $\sigma \circ \delta^j$ corresponds to the vertices with index j omitted,

$$P(\partial\sigma) = \sum_{i < j} (-1)^{i+j} [v_0, \dots, v_i, w_i, \dots, \widehat{w_j}, \dots, w_n] + \sum_{i > j} (-1)^{i-1+j} [v_0, \dots, \widehat{v_j}, \dots, v_i, w_i, \dots, w_n],$$

which is the negative of the terms with $i \neq j$ above. Hence $\partial P + P\partial = g_\# - f_\#$, and chain homotopic maps induce the same map on homology (Lemma 15.3.4). The rest follows from functoriality and Proposition 21.2.5(3). □

Remark 21.3.2. *What the prism operator does.* A homotopy F sweeps each simplex σ of X through the *prism* $\Delta^n \times I$, and $P(\sigma)$ is this prism, pushed into Y by $F \circ (\sigma \times \mathrm{id})$. The prism is not a simplex, and singular chains are made of simplices, so it has to be cut into simplices first: the $n+1$ affine simplices $[v_0, \dots, v_i, w_i, \dots, w_n]$, $0 \le i \le n$, fill $\Delta^n \times I$ and meet along common faces, and the signs $(-1)^i$ orient them coherently. The identity $\partial P + P\partial = g_\# - f_\#$ is then the geometric statement that the boundary of the prism consists of its top $\Delta^n \times \{1\}$, its bottom $\Delta^n \times \{0\}$ with the opposite orientation, and the prisms over the faces of Δ^n, the sides.

1. For $n = 0$, σ is a point x, the prism is the segment $\{x\} \times I$, and $P(x)$ is the path $t \mapsto F(x, t)$ from $f(x)$ to $g(x)$. So $\partial P(x) = g(x) - f(x)$, while $P(\partial x) = 0$.

2. For $n = 1$, σ is a path from x_0 to x_1, and $\Delta^1 \times I$ is a square with bottom edge $[v_0, v_1]$, top edge $[w_0, w_1]$ and vertical sides $[v_0, w_0]$ and $[v_1, w_1]$. The diagonal from v_0 to w_1 cuts it into the two triangles of $P(\sigma) = [v_0, w_0, w_1] - [v_0, v_1, w_1]$. Their boundaries are

   $$\partial[v_0, w_0, w_1] = [w_0, w_1] - [v_0, w_1] + [v_0, w_0], \qquad \partial[v_0, v_1, w_1] = [v_1, w_1] - [v_0, w_1] + [v_0, v_1],$$

   and in the difference the diagonal $[v_0, w_1]$ cancels:

   $$\partial P(\sigma) = [w_0, w_1] - [v_0, v_1] + [v_0, w_0] - [v_1, w_1] = g_\#\sigma - f_\#\sigma - P(\partial\sigma),$$

   since $P(\partial\sigma) = P(x_1) - P(x_0)$ is the path of x_1 minus the path of x_0, that is, $[v_1, w_1] - [v_0, w_0]$. This is the picture behind the general computation: the interior cuts cancel in pairs, and what is left is the top, minus the bottom, minus the sides.

In the de Rham complex the same role is played by the homotopy operator K of Chapter 37, which integrates a form over the I-direction. There no subdivision is needed, because forms can be integrated over the product $\Delta^n \times I$ directly; for chains, which are sums of simplices, the product has to be triangulated, and this is the only reason why P looks more complicated than K.

21.4 Relative homology and exact sequences

Definition 21.4.1. For a subspace $A \subseteq X$, $C_n(X, A) = C_n(X)/C_n(A)$ with the induced boundary, and $H_n(X, A)$ is its homology, the *relative homology*. A map of pairs $f : (X, A) \to (Y, B)$ (a map with $f(A) \subseteq B$) induces $f_* : H_n(X, A) \to H_n(Y, B)$, and homotopic maps of pairs (through maps of pairs) induce the same maps, since the prism operator preserves chains in A.

Theorem 21.4.2. *For $B \subseteq A \subseteq X$ there is a natural long exact sequence*

$$\cdots \to H_n(A, B) \to H_n(X, B) \to H_n(X, A) \xrightarrow{\partial} H_{n-1}(A, B) \to \cdots \to H_0(X, A) \to 0.$$

For $B = \emptyset$ this is the long exact sequence of the pair (X, A), where $\partial[c] = [\partial c]$ for a relative cycle c. The same holds with reduced homology when $B = \emptyset$ and $A \neq \emptyset$.

Proof. The sequence $0 \to C(A, B) \to C(X, B) \to C(X, A) \to 0$ of chain complexes is exact. Apply Theorem 15.4.3. For reduced homology use the augmented complexes, whose quotient is still $C(X, A)$. □

Example 21.4.3. For $x_0 \in X$, the long exact sequence of (X, x_0) in reduced homology gives $H_n(X, x_0) \cong \tilde{H}_n(X)$. If A is a deformation retract of X, then $H_n(X, A) = 0$ for all n, by exactness of the long exact sequence, since $H_n(A) \to H_n(X)$ is an isomorphism for all n (Theorem 21.3.1).

Example 21.4.4. *What relative cycles are.* A chain $c \in C_n(X)$ represents a class in $H_n(X, A)$ when $\partial c \in C_{n-1}(A)$: it is closed "up to A". The simplest case is $X = I = [0, 1]$, $A = \partial I = \{0, 1\}$. Since I is contractible, $\tilde{H}_\bullet(I) = 0$, and the reduced long exact sequence $\tilde{H}_n(I) \to H_n(I, \partial I) \xrightarrow{\partial} \tilde{H}_{n-1}(\partial I) \to \tilde{H}_{n-1}(I)$ shows that ∂ is an isomorphism for every n. By Proposition 21.2.5, $\tilde{H}_\bullet(\partial I)$ is zero except in degree 0, where it is the kernel of the augmentation $\mathbb{Z}\{0\} \oplus \mathbb{Z}\{1\} \to \mathbb{Z}$, generated by $\{1\} - \{0\}$. So $H_n(I, \partial I)$ is $\mathbb{Z}$ for $n = 1$ and 0 otherwise. A generator is the identity path $\iota(t) = t$: it is not a cycle in I, but its boundary $\{1\} - \{0\}$ lies in ∂I, and $\partial[\iota] = [\{1\} - \{0\}]$ is the generator. This is the one-dimensional case of $H_n(D^n, S^{n-1}) \cong \mathbb{Z}$ (Proposition 21.6.4 below).

21.5 Excision and Mayer–Vietoris

Definition 21.5.1. Let $\mathcal{U}$ be a family of subspaces of X whose interiors cover X. Then $C_n^{\mathcal{U}}(X) \subseteq C_n(X)$ is the subgroup generated by singular simplices with image in some $U \in \mathcal{U}$. It is a subcomplex.

Lemma 21.5.2. *There are homomorphisms $S : C_n(X) \to C_n(X)$ and $T : C_n(X) \to C_{n+1}(X)$, natural in X ($f_\# S = S f_\#$, $f_\# T = T f_\#$), with $\partial S = S\partial$ and $\partial T + T\partial = 1 - S$, such that $S(\sigma)$ and $T(\sigma)$ are combinations of simplices with image in $\sigma(\Delta^n)$. Moreover $S^m(\sigma) = \sigma_\#(S^m \iota_n)$ with $\iota_n = [e_0, \ldots, e_n]$, and $S^m \iota_n$ is a combination of affine simplices of diameter at most $(n/(n+1))^m \sqrt{2}$.*

Proof. Linear chains. For a convex $Y \subseteq \mathbb{R}^N$ let $LC_n(Y) \subseteq C_n(Y)$ be generated by the affine simplices $[w_0, \ldots, w_n]$; it is a subcomplex. For $b \in Y$ the *cone* $b : LC_n(Y) \to LC_{n+1}(Y)$, $[w_0, \ldots, w_n] \mapsto [b, w_0, \ldots, w_n]$, satisfies $\partial b(\lambda) = \lambda - b(\partial\lambda)$ for $n \geq 1$, and $\partial b(\lambda) = \lambda - \varepsilon(\lambda)[b]$ for $n = 0$, by the formula for ∂. For an affine simplex λ let b_λ be its barycentre $\frac{1}{n+1} \sum_i w_i$. Define $S = \mathrm{id}$ on LC_0 and $S(\lambda) = b_\lambda(S\partial\lambda)$ for $n \geq 1$; define $T = 0$ on LC_0 and $T(\lambda) = b_\lambda(\lambda - T\partial\lambda)$ for $n \geq 1$.

By induction on n: $\partial S\lambda = S\partial\lambda - b_\lambda(\partial S\partial\lambda) = S\partial\lambda - b_\lambda(S\partial\partial\lambda) = S\partial\lambda$ for $n \geq 2$, and for $n = 1$, $\partial S\lambda = S\partial\lambda - \varepsilon(\partial\lambda)[b_\lambda] = S\partial\lambda$. Similarly, using $\partial T\partial\lambda = \partial\lambda - S\partial\lambda$ by induction, $\partial T\lambda = \lambda - T\partial\lambda - b_\lambda(\partial\lambda - \partial T\partial\lambda) = \lambda - T\partial\lambda - b_\lambda(S\partial\lambda) = \lambda - T\partial\lambda - S\lambda$. Affine maps preserve barycentres and cones, so S and T commute with $g_\#$ for affine maps g.

General chains. Put $S\sigma = \sigma_\# S\iota_n$ and $T\sigma = \sigma_\# T\iota_n$. Naturality is clear, and since $\sigma \circ \delta^i = \sigma_\#\delta^i$ with δ^i affine, $\partial S\sigma = \sigma_\# S\partial\iota_n = \sum_i (-1)^i \sigma_\#\delta^i_\# S\iota_{n-1} = S\partial\sigma$, and likewise for T. By naturality $S^m\sigma = \sigma_\# S^m\iota_n$.

Diameters. The diameter of an affine simplex is the largest distance between its vertices, since $|\sum_i t_i w_i - y| \leq \max_i |w_i - y|$. The simplices of $S\lambda$ are of the form $[b_\lambda, u_0, \dots, u_{n-1}]$ with $[u_0, \dots, u_{n-1}]$ a simplex of S applied to a face of λ. For a vertex w_i, $|b_\lambda - w_i| = |\sum_j (w_j - w_i)|/(n+1) \leq \frac{n}{n+1} \operatorname{diam}\lambda$, so all points of λ are within this distance of b_λ; and by induction the simplices of S of a face have diameter at most $\frac{n-1}{n} \operatorname{diam}\lambda$. So the simplices of $S\lambda$ have diameter at most $\frac{n}{n+1} \operatorname{diam}\lambda$. Iterate, using $\operatorname{diam}\Delta^n = \sqrt{2}$. □

Proposition 21.5.3. *The inclusion $\iota\colon C^{\mathcal{U}}(X) \to C(X)$ is a chain homotopy equivalence. Hence it induces isomorphisms on homology.*

Proof. For a singular simplex $\sigma\colon \Delta^n \to X$ let $m(\sigma)$ be the least $m \geq 0$ such that every subset of Δ^n of diameter at most $(n/(n+1))^m\sqrt{2}$ lies in $\sigma^{-1}(\operatorname{int} U)$ for some $U \in \mathcal{U}$. It exists by the Lebesgue number lemma (Lemma 18.7.3), and by Lemma 21.5.2, $S^i\sigma \in C^{\mathcal{U}}(X)$ for $i \geq m(\sigma)$. The face maps are isometric embeddings and $\frac{n-1}{n} < \frac{n}{n+1}$, so $m(\sigma \circ \delta^j) \leq m(\sigma)$.

Let $D_m = \sum_{0 \leq i < m} TS^i$, so that $\partial D_m + D_m\partial = \sum_i (1 - S)S^i = 1 - S^m$. Define $D\sigma = D_{m(\sigma)}\sigma$ and $\rho = 1 - \partial D - D\partial$. Then ρ is a chain map, and

$$\rho(\sigma) = S^{m(\sigma)}\sigma + (D_{m(\sigma)} - D)\partial\sigma = S^{m(\sigma)}\sigma + \sum_j (-1)^j \sum_{m(\sigma\delta^j) \leq i < m(\sigma)} TS^i(\sigma\delta^j)$$

lies in $C^{\mathcal{U}}(X)$, since T preserves $C^{\mathcal{U}}(X)$. So $\rho\colon C(X) \to C^{\mathcal{U}}(X)$ satisfies $1 - \iota\rho = \partial D + D\partial$. As D maps $C^{\mathcal{U}}(X)$ into itself, the same identity shows $1 - \rho\iota = \partial D + D\partial$ on $C^{\mathcal{U}}(X)$. □

Theorem 21.5.4 (Excision)**.** *Let $Z \subseteq A \subseteq X$ with $\overline{Z} \subseteq \operatorname{int} A$. Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces isomorphisms on all H_n. Equivalently, if $A, B \subseteq X$ with $\operatorname{int} A \cup \operatorname{int} B = X$, then $H_n(B, A \cap B) \to H_n(X, A)$ is an isomorphism.*

Proof. The two statements correspond via $B = X \setminus Z$, since $\operatorname{int} B = X \setminus \overline{Z}$. Let $\mathcal{U} = \{A, B\}$. The map $C(B)/C(A \cap B) \to C^{\mathcal{U}}(X)/C(A)$ is an isomorphism of complexes: it is surjective as every generator of $C^{\mathcal{U}}$ lies in $C(A)$ or $C(B)$, and its kernel is $C(B) \cap C(A) = C(A \cap B)$. The map $C^{\mathcal{U}}(X)/C(A) \to C(X)/C(A)$ induces isomorphisms on homology, by Proposition 21.5.3 and the five lemma applied to the long exact sequences of $0 \to C(A) \to C^{\mathcal{U}}(X) \to C^{\mathcal{U}}(X)/C(A) \to 0$ and $0 \to C(A) \to C(X) \to C(X, A) \to 0$. □

Theorem 21.5.5 (Mayer–Vietoris)**.** *If $A, B \subseteq X$ with $\operatorname{int} A \cup \operatorname{int} B = X$, there is a natural long exact sequence*

$$\cdots \to H_n(A \cap B) \xrightarrow{(i_*, -j_*)} H_n(A) \oplus H_n(B) \xrightarrow{k_* + l_*} H_n(X) \xrightarrow{\partial} H_{n-1}(A \cap B) \to \cdots,$$

where i, j, k, l are the inclusions, and similarly in reduced homology if $A \cap B \neq \emptyset$.

Proof. The sequence $0 \to C(A \cap B) \xrightarrow{(x \mapsto (x, -x))} C(A) \oplus C(B) \xrightarrow{((x,y) \mapsto x+y)} C^{\{A,B\}}(X) \to 0$ is exact: the kernel of the second map consists of pairs $(x, -x)$ with $x \in C(A) \cap C(B) = C(A \cap B)$. Take the long exact sequence and replace $H_n(C^{\{A,B\}}(X))$ by $H_n(X)$ using Proposition 21.5.3. For reduced homology augment each complex by $\mathbb{Z}$, $\mathbb{Z} \oplus \mathbb{Z}$, $\mathbb{Z}$. □

Remark 21.5.6. *How to compute the connecting map.* By Proposition 21.5.3, every class in $H_n(X)$ is represented by a cycle z that is a sum of simplices lying in A or in B; write $z = a + b$ with $a \in C_n(A)$ and $b \in C_n(B)$ (simplices in $A \cap B$ may go to either side). Then $\partial a = -\partial b$ lies in $C_{n-1}(A) \cap C_{n-1}(B) = C_{n-1}(A \cap B)$, it is a cycle, and

$$\partial[z] = [\partial a] \in H_{n-1}(A \cap B).$$

Indeed, in the description of the connecting map in Theorem 15.4.3, (a, b) is a preimage of z, and its boundary $(\partial a, \partial b) = (\partial a, -\partial a)$ is the image of ∂a. In words: cut the cycle into a piece in A and a piece in B; the common boundary of the pieces is the image of the cycle.

21.6 Spheres, good pairs and degree

Theorem 21.6.1. *For $n \geq 0$, $\tilde{H}_k(S^n) \cong \mathbb{Z}$ for $k = n$ and 0 otherwise. For $n \geq 1$ the Mayer–Vietoris connecting map is an isomorphism $\tilde{H}_k(S^n) \to \tilde{H}_{k-1}(S^{n-1})$, where $S^{n-1} \subseteq S^n$ is the equator $\{x_{n+1} = 0\}$.*

Proof. For $n = 0$, S^0 is two points and $\tilde{H}_0(S^0) \cong \mathbb{Z}$, generated by the difference of the two points. For $n \geq 1$ let $A = \{x \in S^n : x_{n+1} > -1/2\}$ and $B = \{x_{n+1} < 1/2\}$. By stereographic projection from $\mp e_{n+1}$ (Example 18.9.4), A and B are homeomorphic to open balls, hence contractible, and $A \cap B$ deformation retracts onto the equator via $H(x, t) = ((1-t)x + t(x', 0))/\|(1-t)x + t(x', 0)\|$, where $x = (x', x_{n+1})$ with $x' \neq 0$. The reduced Mayer–Vietoris sequence gives the isomorphism, and induction gives the result. □

Example 21.6.2. *A generator of $H_1(S^1)$.* For $n = 1$ the proof uses $A = \{x_2 > -\frac{1}{2}\}$ and $B = \{x_2 < \frac{1}{2}\}$ in $S^1 \subseteq \mathbb{R}^2$; their intersection consists of two arcs, one containing $p = (1, 0)$ and one containing $q = (-1, 0)$. Let

$$a(t) = \big(1 - 2t, 2\sqrt{t(1-t)}\big), \qquad b(t) = \big(2t - 1, -2\sqrt{t(1-t)}\big), \qquad t \in I,$$

the upper half circle from p to q and the lower half circle from q to p (indeed $(1-2t)^2 + 4t(1-t) = 1$). Then a lies in A, b lies in B, and $z = a + b$ is a cycle, as in Example 21.2.3(1). By Remark 21.5.6, $\partial[z] = [\partial a] = [\{q\} - \{p\}]$, which generates $\tilde{H}_0(A \cap B) \cong \mathbb{Z}$, as p and q lie in different path components. Since ∂ is an isomorphism, $[z]$ generates $H_1(S^1) \cong \mathbb{Z}$. In particular z is not a boundary: the circle has a hole that the cycle z goes around once. Neither half a nor b is a cycle by itself; the connecting map detects precisely how the two halves are glued.

Definition 21.6.3. A pair (X, A) is *good* if A is a nonempty closed subspace that is a deformation retract of some open neighbourhood V of A in X.

Proposition 21.6.4. *For a good pair, the quotient map $q\colon (X, A) \to (X/A, A/A)$ induces isomorphisms $H_n(X, A) \cong H_n(X/A, A/A) \cong \tilde{H}_n(X/A)$. For example, for $n \geq 1$, (D^n, S^{n-1}) is good and $H_k(D^n, S^{n-1}) \cong \tilde{H}_k(S^n) \cong \tilde{H}_{k-1}(S^{n-1})$.*

Proof. Consider the commutative diagram

$$\begin{array}{ccccc}
H_n(X, A) & \longrightarrow & H_n(X, V) & \longleftarrow & H_n(X \setminus A, V \setminus A) \\
\downarrow{\scriptstyle q_*} & & \downarrow{\scriptstyle q_*} & & \downarrow{\scriptstyle q_*} \\
H_n(X/A, A/A) & \longrightarrow & H_n(X/A, V/A) & \longleftarrow & H_n(X/A \setminus A/A, V/A \setminus A/A)
\end{array}$$

The upper left map is an isomorphism by the long exact sequence of the triple (X, V, A), since $H_n(V, A) = 0$ (Example 21.4.3). The upper right map is an isomorphism by excision, as $\overline{A} = A \subseteq V = \operatorname{int} V$. Since V is open and saturated, the deformation retraction of V induces one of V/A onto the point A/A (Lemma 19.2.4), so the lower maps are isomorphisms for the same reasons. The right vertical map is induced by a homeomorphism of pairs, because q restricts to a bijective quotient map $X \setminus A \to X/A \setminus A/A$ (again by Lemma 19.2.4, as $X \setminus A$ is open and saturated). So the left vertical map is an isomorphism. The last isomorphism is Example 21.4.3. For (D^n, S^{n-1}) take $V = D^n \setminus \{0\}$ (Example 19.2.3); D^n/S^{n-1} is compact, and the map $D^n \to S^n$, $x \mapsto (2\sqrt{1 - \|x\|^2}\, x, 2\|x\|^2 - 1)$, induces a continuous bijection $D^n/S^{n-1} \to S^n$, hence a homeomorphism. The last isomorphism follows from the long exact sequence of (D^n, S^{n-1}). □

Definition 21.6.5. The *degree* of a map $f\colon S^n \to S^n$ is the integer $\deg f$ such that f_* is multiplication by $\deg f$ on $\tilde{H}_n(S^n) \cong \mathbb{Z}$.

Proposition 21.6.6. *1.* $\deg \mathrm{id} = 1$, $\deg(fg) = \deg f \deg g$, *and homotopic maps have the same degree; a map that is not surjective has degree* 0.

2. *A reflection* $x \mapsto (x_1, \dots, -x_i, \dots, x_{n+1})$ *has degree* -1, *and the antipodal map has degree* $(-1)^{n+1}$.

3. *A map* $f\colon S^n \to S^n$ *without fixed points is homotopic to the antipodal map, so* $\deg f = (-1)^{n+1}$.

Proof. (1) Functoriality and homotopy invariance; a non-surjective map factors through $S^n \setminus \{\mathrm{pt}\} \cong \mathbb{R}^n$, which is contractible.

(2) Let r be the reflection in the first coordinate. For $n = 0$ it swaps the two points and acts by -1 on $\tilde{H}_0(S^0)$. For $n \geq 1$, r preserves the sets A, B of the proof of Theorem 21.6.1 and commutes with the deformation retraction of $A \cap B$ onto the equator, on which it is again the reflection in the first coordinate. By naturality of the Mayer–Vietoris sequence, $\deg r$ on S^n equals $\deg r$ on S^{n-1}, hence equals -1. A reflection in the i-th coordinate is $\pi r \pi^{-1}$ for a coordinate permutation π, so has degree -1 by (1). The antipodal map is the composite of $n + 1$ reflections.

(3) $(1 - t)f(x) - tx$ never vanishes: otherwise $f(x) = \frac{t}{1-t}x$ with $\|f(x)\| = \|x\| = 1$ forces $f(x) = x$. Normalising gives a homotopy from f to $-\mathrm{id}$. □

Corollary 21.6.7. *1. (Brouwer) There is no retraction* $D^{n+1} \to S^n$, *and every map* $D^{n+1} \to D^{n+1}$ *has a fixed point.*

2. *(Hairy ball theorem)* S^n *has a continuous nowhere vanishing tangent vector field* ($v\colon S^n \to \mathbb{R}^{n+1}$ *with* $\langle v(x), x\rangle = 0$) *if and only if* n *is odd.*

3. *(Invariance of dimension) If nonempty open subsets* $U \subseteq \mathbb{R}^m$ *and* $V \subseteq \mathbb{R}^n$ *are homeomorphic, then* $m = n$.

Proof. (1) $\tilde{H}_n(S^n) \neq 0$ while D^{n+1} is contractible, so the identity of $\tilde{H}_n(S^n)$ cannot factor through $\tilde{H}_n(D^{n+1}) = 0$. The formula in the proof of Corollary 19.4.8 turns a fixed point free map into a retraction.

(2) If $n = 2k - 1$, $v(x) = (-x_2, x_1, \dots, -x_{2k}, x_{2k-1})$ works. Conversely, if v never vanishes, let $u = v/\|v\|$. Since $x \perp u(x)$ are unit vectors, $(1 - t)x + tu(x)$ and $(1 - t)u(x) - tx$ never vanish, and normalising gives homotopies $\mathrm{id} \simeq u \simeq -\mathrm{id}$. So $1 = (-1)^{n+1}$ and n is odd.

(3) Let $x \in U$. By excision (removing the closed set $\mathbb{R}^m \setminus U$ from $\mathbb{R}^m \setminus \{x\}$) and the long exact sequence, $H_k(U, U \setminus \{x\}) \cong H_k(\mathbb{R}^m, \mathbb{R}^m \setminus \{x\}) \cong \tilde{H}_{k-1}(\mathbb{R}^m \setminus \{x\}) \cong \tilde{H}_{k-1}(S^{m-1})$ for $m \geq 1$, which is nonzero exactly for $k = m$. A homeomorphism $U \to V$ gives isomorphisms of these local homology groups. For $m = 0$ or $n = 0$ the spaces are points, and a nonempty open subset of $\mathbb{R}^n$ is a point only if $n = 0$. □

21.7 Cellular homology

Lemma 21.7.1. *Let X be a CW complex (Definition 19.7.1).*

1. *$H_k(X^n, X^{n-1})$ is zero for $k \neq n$, and free abelian with basis the classes e_α of the characteristic maps $\Phi_\alpha \colon (D^n, S^{n-1}) \to (X^n, X^{n-1})$ applied to a fixed generator of $H_n(D^n, S^{n-1}) \cong \mathbb{Z}$, for $k = n$.*

2. *$H_k(X^n) = 0$ for $k > n$.*

3. *The inclusion $X^n \to X$ induces an isomorphism $H_k(X^n) \to H_k(X)$ for $k < n$.*

Proof. (1) X^{n-1} is closed in X^n (as in the proof of Proposition 19.5.5), and it is a deformation retract of the open set obtained by removing the centres of the n-cells, via the radial deformation of $D^n \setminus \{0\}$ onto S^{n-1}, which descends to the quotient by Lemma 19.2.4. So (X^n, X^{n-1}) is a good pair, and so is $(\coprod_\alpha D^n_\alpha, \coprod_\alpha S^{n-1}_\alpha)$. The characteristic maps induce a continuous bijection $\coprod_\alpha D^n_\alpha / \coprod_\alpha S^{n-1}_\alpha \to X^n/X^{n-1}$, which is a homeomorphism: a set whose preimage in $\coprod_\alpha D^n_\alpha$ is open has open preimage in $X^{n-1} \sqcup \coprod_\alpha D^n_\alpha$, since that preimage meets X^{n-1} in $\emptyset$ or X^{n-1}. By Proposition 21.6.4 and its naturality, $H_k(X^n, X^{n-1}) \cong H_k(\coprod_\alpha D^n_\alpha, \coprod_\alpha S^{n-1}_\alpha) = \bigoplus_\alpha H_k(D^n, S^{n-1})$, which is $\bigoplus_\alpha \mathbb{Z}$ for $k = n$ and 0 otherwise. (For $n = 0$, $X^{-1} = \emptyset$ and $H_k(X^0)$ is computed by Proposition 21.2.5.)

(2) By the exact sequence $H_k(X^{n-1}) \to H_k(X^n) \to H_k(X^n, X^{n-1})$ and induction on n, starting from $X^{-1} = \emptyset$.

(3) For $k < n$ the exact sequence $H_{k+1}(X^{n+1}, X^n) \to H_k(X^n) \to H_k(X^{n+1}) \to H_k(X^{n+1}, X^n)$ has outer terms zero, so $H_k(X^n) \cong H_k(X^m)$ for all $m \geq n$. A singular chain has compact image, which lies in a finite subcomplex (Theorem 19.7.4(2)), hence in some X^m. So every cycle of X is a cycle of some X^m, and a cycle of X^n that bounds in X bounds in some X^m; this gives surjectivity and injectivity. □

Definition 21.7.2. The *cellular chain complex* of a CW complex X has $C^{CW}_n(X) = H_n(X^n, X^{n-1})$ and differential d_n the composite $H_n(X^n, X^{n-1}) \xrightarrow{\partial} H_{n-1}(X^{n-1}) \xrightarrow{j_{n-1}} H_{n-1}(X^{n-1}, X^{n-2})$. Then $d_{n-1}d_n = 0$ because it contains two consecutive maps $\partial \circ j_{n-1}$ of the long exact sequence of (X^{n-1}, X^{n-2}). Its homology is the *cellular homology* $H^{CW}_n(X)$.

Theorem 21.7.3. *$H^{CW}_n(X) \cong H_n(X)$ for every CW complex X.*

Proof. Write $j_n \colon H_n(X^n) \to H_n(X^n, X^{n-1})$, which is injective since $H_n(X^{n-1}) = 0$ by Lemma 21.7.1(2), and $\partial_{n+1} \colon H_{n+1}(X^{n+1}, X^n) \to H_n(X^n)$, so $d_{n+1} = j_n \partial_{n+1}$. Since j_n is injective, $\ker d_n = \ker(j_{n-1}\partial_n) = \ker \partial_n = \operatorname{im} j_n$, and j_n maps $\operatorname{im} \partial_{n+1}$ isomorphically onto $\operatorname{im} d_{n+1}$. Hence $H^{CW}_n(X) \cong \operatorname{im} j_n / \operatorname{im} d_{n+1} \cong H_n(X^n)/\operatorname{im} \partial_{n+1}$. By the exact sequence $H_{n+1}(X^{n+1}, X^n) \xrightarrow{\partial_{n+1}} H_n(X^n) \to H_n(X^{n+1}) \to H_n(X^{n+1}, X^n) = 0$, this is $H_n(X^{n+1})$, which is $H_n(X)$ by Lemma 21.7.1(3). □

Theorem 21.7.4 (Cellular boundary formula)**.** *For $n \geq 2$, $d_n(e^n_\alpha) = \sum_\beta d_{\alpha\beta} e^{n-1}_\beta$, where $d_{\alpha\beta}$ is the degree of the composite $S^{n-1} \xrightarrow{\varphi_\alpha} X^{n-1} \to X^{n-1}/(X^{n-1} \setminus e^{n-1}_\beta) \cong S^{n-1}$ of the attaching map with the map collapsing the complement of the cell e^{n-1}_β (identified with S^{n-1} via Φ_β). For $n = 1$, $d_1(e^1_\alpha)$ is the difference of the endpoint and the starting point of the 1-cell.*

This is [Hat02, Section 2.2, Cellular Boundary Formula]; the proof is a diagram chase using naturality of the long exact sequences for the characteristic maps.

Example 21.7.5. 1. If all cells of X are in even dimensions, all d_n vanish and $H_n(X)$ is free with basis the n-cells. For $\mathbb{CP}^n$ (one cell in each even dimension $\leq 2n$), $H_k(\mathbb{CP}^n) \cong \mathbb{Z}$ for k even with $0 \leq k \leq 2n$, and 0 otherwise.

2. For the closed orientable surface Σ_g of genus g (Example 19.7.2), $d_1 = 0$ (one 0-cell) and $d_2 = 0$ (each 1-cell appears twice in the attaching word with opposite signs), so $H_0 = \mathbb{Z}$, $H_1 = \mathbb{Z}^{2g}$, $H_2 = \mathbb{Z}$.

3. For $\mathbb{RP}^n$ with one cell in each dimension, d_k is multiplication by $1 + (-1)^k$ [Hat02, Example 2.42]. So $H_k(\mathbb{RP}^n)$ is $\mathbb{Z}$ for $k = 0$, $\mathbb{Z}/2\mathbb{Z}$ for k odd with $0 < k < n$, $\mathbb{Z}$ for $k = n$ odd, and 0 otherwise.

Definition 21.7.6. The *Euler characteristic* of a finite CW complex with c_n cells of dimension n is $\chi(X) = \sum_n (-1)^n c_n$.

Proposition 21.7.7. $\chi(X) = \sum_n (-1)^n \dim_{\mathbb{Q}}(H_n(X) \otimes \mathbb{Q})$. *In particular $\chi(X)$ depends only on the homotopy type of X.*

Proof. $\mathbb{Q} = S^{-1}\mathbb{Z}$ is a flat $\mathbb{Z}$-module (Proposition 14.3.2), so $H_n(C^{CW} \otimes \mathbb{Q}) \cong H_n(C^{CW}) \otimes \mathbb{Q} \cong H_n(X) \otimes \mathbb{Q}$. For a bounded complex V of finite-dimensional vector spaces, rank–nullity (Theorem 11.2.6) gives $\dim V_n = \dim Z_n + \dim B_{n-1}$ and $\dim H_n = \dim Z_n - \dim B_n$, so $\sum (-1)^n \dim V_n = \sum (-1)^n \dim H_n$. Apply this to $C^{CW} \otimes \mathbb{Q}$, with dim $= c_n$. □

Example 21.7.8. $\chi(S^n) = 1 + (-1)^n$, $\chi(\Sigma_g) = 2 - 2g$, $\chi(\mathbb{CP}^n) = n + 1$, $\chi(\mathbb{RP}^n) = 1$ for n even and 0 for n odd. As $\chi(\Sigma_g)$ determines g, surfaces of different genus are not homotopy equivalent.

21.8 Homology with coefficients

Definition 21.8.1. For an abelian group G, $C_n(X, A; G) = C_n(X, A) \otimes_{\mathbb{Z}} G$, and $H_n(X, A; G)$ is its homology. For a ring R these are R-modules.

Theorem 21.8.2. *1. Homotopy invariance, the long exact sequences, excision and Mayer–Vietoris hold for $H_\bullet(-; G)$, and cellular homology with coefficients, computed from $C^{CW}_\bullet(X) \otimes G$, agrees with $H_\bullet(X; G)$.*

2. (Universal coefficients) There is a natural short exact sequence $0 \to H_n(X, A) \otimes G \to H_n(X, A; G) \to \operatorname{Tor}^{\mathbb{Z}}_1(H_{n-1}(X, A), G) \to 0$. It splits, non-naturally [Hat02, Theorem 3A.3].

Proof. (1) The complexes $C(X, A)$ are free, so the short exact sequences of chain complexes used above are degreewise split and remain exact after $\otimes G$; chain homotopies remain chain homotopies. The arguments therefore apply verbatim, and the proof of Theorem 21.7.3 goes through with $H_n(X^n, X^{n-1}; G) \cong C^{CW}_n(X) \otimes G$. (2) Apply the Künneth formula (Theorem 15.9.1) to the free complex $C(X, A)$ and the complex G concentrated in degree 0. The splitting is quoted. □

Example 21.8.3. With coefficients in $\mathbb{F}_2 = \mathbb{Z}/2\mathbb{Z}$ all cellular differentials of $\mathbb{RP}^n$ vanish, since $1 + (-1)^k$ is even; so $H_k(\mathbb{RP}^n; \mathbb{F}_2) \cong \mathbb{F}_2$ for $0 \leq k \leq n$. With coefficients in a field F of characteristic 0, $H_\bullet(X; F) \cong H_\bullet(X) \otimes F$, because F is a $\mathbb{Q}$-vector space, hence a direct sum of copies of the flat module $\mathbb{Q}$, so $\operatorname{Tor}^{\mathbb{Z}}_1(-, F) = 0$ (Proposition 15.8.4).

21.9 The Hurewicz theorems

Theorem 21.9.1 (Hurewicz in degree one)**.** *Let X be path-connected and $x_0 \in X$. Regarding a loop as a singular 1-simplex via $\Delta^1 \cong I$, $(t_0, t_1) \mapsto t_1$, gives a well-defined homomorphism $h\colon \pi_1(X, x_0) \to H_1(X)$, which induces an isomorphism $\pi_1(X, x_0)^{\mathrm{ab}} \cong H_1(X)$ from the abelianisation (Proposition 7.9.2).*

Proof. For paths we write $f \sim g$ if $f - g \in C_1(X)$ is a boundary. (i) A constant path c satisfies $c \sim 0$: it is the boundary of the constant 2-simplex. (ii) If $f \simeq g$ relative to endpoints via $F\colon I^2 \to X$, divide I^2 into two triangles along the diagonal and compose with F; the boundary of the difference of the two resulting 2-simplices is $f - g$ plus constant paths, so $f \sim g$. (iii) $f * g \sim f + g$: the 2-simplex $\sigma = (f * g) \circ \pi$, where $\pi\colon \Delta^2 \to I$ is the affine map with $e_0 \mapsto 0$, $e_1 \mapsto 1/2$, $e_2 \mapsto 1$, has $\partial\sigma = g - f * g + f$. (iv) Hence $f + \bar{f} \sim f * \bar{f} \sim c \sim 0$. So h is well defined and a homomorphism, and it factors through π_1^{ab} as $H_1(X)$ is abelian.

Choose for each $x \in X$ a path γ_x from x_0 to x, with γ_{x_0} constant. For a singular 1-simplex τ let $L(\tau) = [\gamma_{\tau(0)} * \tau * \bar{\gamma}_{\tau(1)}]$ in $\pi_1(X, x_0)^{\mathrm{ab}}$, written additively, and extend L linearly to $C_1(X)$. For a singular 2-simplex σ with edges τ_0, τ_1, τ_2 (so $\partial\sigma = \tau_0 - \tau_1 + \tau_2$), $L(\partial\sigma)$ is the class of the loop $\gamma_{\sigma(e_0)} * \tau_2 * \tau_0 * \bar{\tau}_1 * \bar{\gamma}_{\sigma(e_0)}$, which is null-homotopic because the loop around the boundary of Δ^2 is null-homotopic in the contractible space Δ^2. So L induces $\bar{L}\colon H_1(X) \to \pi_1(X, x_0)^{\mathrm{ab}}$. Clearly $\bar{L}h = \mathrm{id}$. For a cycle $z = \sum n_i \tau_i$, by (iii) and (iv), $hL(z) = \sum n_i(\gamma_{\tau_i(0)} + \tau_i - \gamma_{\tau_i(1)}) = z - \Gamma(\partial z) = z$ in $H_1(X)$, where $\Gamma\colon C_0(X) \to C_1(X)$ is the homomorphism $x \mapsto \gamma_x$. So h and $\bar{L}$ are inverse isomorphisms. □

In higher degrees, homotopy groups are related to homology in the same way, as long as the lower homotopy groups vanish. Let $n \geq 1$ and fix a generator $[S^n]$ of $H_n(S^n) \cong \mathbb{Z}$ (Theorem 21.6.1). A map $f\colon (I^n, \partial I^n) \to (X, x_0)$ factors through the quotient $I^n/\partial I^n \cong S^n$, and so induces $f_*\colon H_n(S^n) \to H_n(X)$. The *Hurewicz map* is

$$h_n\colon \pi_n(X, x_0) \to H_n(X), \qquad [f] \mapsto f_*[S^n].$$

It is well defined, since homotopic maps induce the same map in homology (Theorem 21.3.1), and it is a homomorphism [Hat02, Section 4.2]; for $n = 1$ it is the map h of Theorem 21.9.1. A space X is *n-connected* if it is path-connected and $\pi_k(X, x_0) = 0$ for $1 \leq k \leq n$; so 0-connected means path-connected and 1-connected means simply connected.

Theorem 21.9.2 (Hurewicz)**.** *Let $n \geq 2$ and let X be an $(n-1)$-connected space. Then $\tilde{H}_k(X) = 0$ for $k < n$, and the Hurewicz map $h_n\colon \pi_n(X, x_0) \to H_n(X)$ is an isomorphism.*

This is [Hat02, Theorem 4.32], where a relative version is also proved; we do not prove it here. In words: *the first nonvanishing homotopy group of a simply connected space is its first nonvanishing reduced homology group.* For $n = 1$ the analogous statement is Theorem 21.9.1, with the abelianisation; for $n \geq 2$ the group π_n is already abelian (Proposition 19.8.2), and no correction is needed.

Example 21.9.3.

1. For $n \geq 2$ the sphere S^n is $(n-1)$-connected (Remark 19.8.8), so $\pi_n(S^n) \cong H_n(S^n) \cong \mathbb{Z}$, generated by the class of the identity. Composing with h_n, the homotopy class of a map $S^n \to S^n$ is detected by its degree.
2. A wedge $\bigvee_\alpha S^n$ of n-spheres with $n \geq 2$ is $(n-1)$-connected (by cellular approximation, as for a single sphere), so $\pi_n(\bigvee_\alpha S^n) \cong \bigoplus_\alpha \mathbb{Z}$ by Exercise 21.10.3: one generator for each sphere.
3. The Hurewicz theorem says nothing about the groups above the first nonvanishing one. For S^2, $\pi_3(S^2) \cong \mathbb{Z}$ while $H_3(S^2) = 0$ (Remark 19.8.8): higher homotopy groups are not determined by homology.

Counterexample 21.9.4. For $n = 2$ the hypothesis that X is simply connected cannot be dropped. Let $X = S^1 \vee S^2$. Then $H_2(X) \cong \mathbb{Z}$ (Exercise 21.10.3), but $\pi_2(X)$ is a free abelian group of infinite rank. Indeed, the universal cover $\widetilde{X}$ is the real line with a copy of S^2 attached at each integer, and by Proposition 19.8.3 $\pi_2(X) \cong \pi_2(\widetilde{X})$. Collapsing the contractible line shows that $\widetilde{X}$ is homotopy equivalent to the wedge $\bigvee_{m\in\mathbb{Z}} S^2$, which is simply connected, so $\pi_2(\widetilde{X}) \cong \bigoplus_{m\in\mathbb{Z}} \mathbb{Z}$ by Example 21.9.3(2). The group $\pi_1(X) \cong \mathbb{Z}$ acts on $\pi_2(X)$ by translating the spheres, and $H_2(X)$ only sees the quotient by this action.

Remark 21.9.5. Combined with Whitehead's theorem (Theorem 19.8.6), the Hurewicz theorem gives a criterion that only involves homology: a map between simply connected CW complexes that induces isomorphisms on all homology groups is a homotopy equivalence [Hat02, Corollary 4.33]. Simple connectivity is needed here too: the Poincaré homology sphere with a point removed has the homology of a point, but it is not contractible, since its fundamental group is a nontrivial perfect group (equal to its commutator subgroup, so that its abelianisation H_1 vanishes).

Remark 21.9.6. Homotopy invariance, the long exact sequence, excision, additivity over disjoint unions and the value on a point are the *Eilenberg–Steenrod axioms*. On CW complexes they determine homology, as the proof of Theorem 21.7.3 shows. Other constructions satisfying them, such as simplicial, Čech or sheaf-theoretic homology on suitable spaces, agree with singular homology there; the comparison with de Rham cohomology is Chapter 37.

21.10 Exercises

Exercise 21.10.1. Show that S^m and S^n are homotopy equivalent only if $m = n$, and that $\mathbb{R}^m \setminus \{0\}$ and $\mathbb{R}^n \setminus \{0\}$ are homeomorphic only if $m = n$.

Solution. By Theorem 21.6.1, $\tilde{H}_\bullet(S^m)$ is nonzero only in degree m. The spaces $\mathbb{R}^m \setminus \{0\}$ and S^{m-1} are homotopy equivalent (Example 19.2.3). □

Exercise 21.10.2. The *suspension* SX is the quotient of $X \times [-1, 1]$ collapsing $X \times \{1\}$ and $X \times \{-1\}$ to two points. Show that $\tilde{H}_{n+1}(SX) \cong \tilde{H}_n(X)$ for all n.

Solution. Let A and B be the images of $X \times (-1/2, 1]$ and $X \times [-1, 1/2)$. They are contractible (slide to the cone points; the homotopies descend by Lemma 19.2.4), and $A \cap B \cong X \times (-1/2, 1/2) \simeq X$. The reduced Mayer–Vietoris sequence gives the isomorphism. □

Exercise 21.10.3. Show that $\tilde{H}_n(\bigvee_\alpha X_\alpha) \cong \bigoplus_\alpha \tilde{H}_n(X_\alpha)$ if the basepoints x_α are such that each (X_α, x_α) is a good pair. Compute $H_\bullet$ of a wedge of k circles.

Solution. The pair $(\coprod X_\alpha, \coprod \{x_\alpha\})$ is good with quotient $\bigvee X_\alpha$, so $\tilde{H}_n(\bigvee X_\alpha) \cong H_n(\coprod X_\alpha, \coprod\{x_\alpha\}) = \bigoplus H_n(X_\alpha, x_\alpha) = \bigoplus \tilde{H}_n(X_\alpha)$. For k circles, $H_0 = \mathbb{Z}$, $H_1 = \mathbb{Z}^k$, and $H_n = 0$ for $n \geq 2$; this agrees with Theorem 21.9.1, since the abelianisation of a free group of rank k is $\mathbb{Z}^k$. □

Exercise 21.10.4. Using Theorem 21.9.1 and Remark 19.4.7, show that the degree of a map $S^1 \to S^1$ defined via π_1 agrees with the homological degree.

Exercise 21.10.5. Let X be a finite CW complex and $f : X \to X$ a cellular map. Define the Lefschetz number $\Lambda(f) = \sum_n (-1)^n \operatorname{tr}(f_* \mid H_n(X; \mathbb{Q}))$. Show that $\Lambda(f) = \sum_n (-1)^n \operatorname{tr}(f_\# \mid C_n^{CW}(X) \otimes \mathbb{Q})$, and deduce that $\Lambda(\mathrm{id}) = \chi(X)$.

Solution. A cellular map sends X^n into X^n, so it is a map of pairs $(X^n, X^{n-1}) \to (X^n, X^{n-1})$ and induces maps $f_\#$ on $C_n^{CW}(X)$; they commute with the differentials, which are composites of maps of long exact sequences. The isomorphism $H_n^{CW}(X) \cong H_n(X)$ of Theorem 21.7.3 is built from maps induced by inclusions and connecting maps, so it is compatible with f; the same holds with coefficients in $\mathbb{Q}$ (Theorem 21.8.2).

It remains to prove the *Hopf trace formula*: if V is a bounded complex of finite-dimensional vector spaces and φ a chain map from V to itself, then $\sum_n (-1)^n \operatorname{tr}(\varphi \mid V_n) = \sum_n (-1)^n \operatorname{tr}(\varphi \mid H_n(V))$. The subspaces $B_n \subseteq Z_n \subseteq V_n$ are preserved by φ. Choosing a basis of B_n, extending it to Z_n and then to V_n, the matrix of φ on V_n is block upper triangular, with diagonal blocks the matrices of φ on B_n, on $Z_n/B_n = H_n$ and on V_n/Z_n. The differential induces an isomorphism $V_n/Z_n \cong B_{n-1}$ compatible with φ, so $\operatorname{tr}(\varphi \mid V_n) = \operatorname{tr}(\varphi \mid B_n) + \operatorname{tr}(\varphi \mid H_n) + \operatorname{tr}(\varphi \mid B_{n-1})$. In the alternating sum the terms with B cancel, as in the proof of Proposition 21.7.7. For $f = \mathrm{id}$, the trace on $C_n^{CW}(X) \otimes \mathbb{Q} \cong \mathbb{Q}^{c_n}$ is c_n, so $\Lambda(\mathrm{id}) = \chi(X)$. □

Exercise 21.10.6. The Klein bottle K is obtained from $S^1 \vee S^1$ by attaching a 2-cell along $aba^{-1}b$. Compute $\pi_1(K)$, $H_\bullet(K)$ and $H_\bullet(K; \mathbb{F}_2)$.

Solution. By Proposition 19.5.5 and Example 19.5.4, $\pi_1(K) \cong \langle a, b \mid aba^{-1}b \rangle$. The cellular chain complex has one 0-cell, two 1-cells a, b and one 2-cell e. Since there is one 0-cell, $d_1 = 0$. The degrees in the cellular boundary formula are the sums of the exponents of each letter in the attaching word, as in Example 21.7.5(2) [Hat02, Section 2.2]: a occurs with exponents $+1$ and -1, and b twice with exponent $+1$. So $d_2(e) = 2b$, and

$$H_0(K) \cong \mathbb{Z}, \qquad H_1(K) \cong \mathbb{Z}^2/\langle (0,2) \rangle \cong \mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}, \qquad H_2(K) = \ker d_2 = 0.$$

This agrees with Theorem 21.9.1: abelianising the relation $aba^{-1}b = 1$ gives $2b = 0$. With coefficients in $\mathbb{F}_2$ the differential $d_2 = 2b$ becomes 0, so $H_k(K; \mathbb{F}_2)$ is $\mathbb{F}_2$, $\mathbb{F}_2^2$, $\mathbb{F}_2$ for $k = 0, 1, 2$; for instance $H_2(K; \mathbb{F}_2) \cong \operatorname{Tor}_1^{\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z}, \mathbb{F}_2) \cong \mathbb{F}_2$ by universal coefficients. Both computations give $\chi(K) = 1 - 2 + 1 = 0$. Unlike the torus, $H_2(K; \mathbb{Z}) = 0$: the 2-cell is not a cycle, which reflects the fact that K is not orientable. □

Exercise 21.10.7. Let n be even.

1. Show that for every map $f : S^n \to S^n$ there is a point x with $f(x) = x$ or $f(x) = -x$.
2. Show that if a group G acts on S^n by homeomorphisms *freely*, that is, no $g \neq 1$ has a fixed point, then G has at most two elements. (The antipodal map gives a free action of $\mathbb{Z}/2\mathbb{Z}$, with quotient $\mathbb{RP}^n$.)

For odd n both statements fail: on $S^1 \subseteq \mathbb{C}$, the rotation by a right angle moves every point to a point that is neither equal nor opposite to it, and rotations by multiples of $2\pi/k$ give a free action of $\mathbb{Z}/k\mathbb{Z}$.

Solution. (1) Let α be the antipodal map, of degree $(-1)^{n+1} = -1$ (Proposition 21.6.6(2)). If f has no fixed point, then $\deg f = -1$ by Proposition 21.6.6(3). If $f(x) \neq -x$ for all x, then $\alpha \circ f$ has no fixed point, so $-\deg f = \deg(\alpha f) = -1$ and $\deg f = 1$. The two cannot both hold.

(2) Each $g \in G$ acts by a homeomorphism, and $\deg g \cdot \deg g^{-1} = \deg \mathrm{id} = 1$, so $\deg g = \pm 1$, and $g \mapsto \deg g$ is a homomorphism $G \to \{\pm 1\}$ by Proposition 21.6.6(1). If $g \neq 1$, then g has no fixed point, so $\deg g = -1$. Hence the homomorphism is injective, and $|G| \leq 2$. □

Chapter 22

Singular Cohomology

22.1 Introduction

Cohomology is obtained by dualising singular chains. As groups it carries the same information as homology, by the universal coefficient theorem, but it has a natural ring structure given by the cup product, which distinguishes spaces with the same homology (Example 22.5.2). Cohomology classes are the objects of the Hodge conjecture: a Hodge class is a rational cohomology class of a special type, and the conjecture asks whether it is a combination of classes of subvarieties. The cap product relates cohomology and homology and leads to Poincaré duality (Chapter 23). We follow [Hat02, Chapter 3].

Prerequisites. Chapter 21 (Singular Homology).

On the way to the Hodge conjecture. Needed: cochains and cohomology, the cup product, the Künneth formula, the cohomology rings of projective spaces and the cap product. Section 22.6 can be skipped.

Throughout, R is a commutative ring and G an abelian group, written additively.

22.2 Cochains and cohomology

Definition 22.2.1. For a pair (X, A) let $C^n(X, A; G) = \operatorname{Hom}_{\mathbb{Z}}(C_n(X, A), G)$, the group of *singular n-cochains*, with coboundary $\delta\colon C^n \to C^{n+1}$, $\delta\varphi = \varphi \circ \partial$. So $C^n(X, A; G)$ is the group of functions from singular n-simplices of X to G vanishing on simplices in A, and $(\delta\varphi)(\sigma) = \sum_i (-1)^i \varphi(\sigma \circ \delta^i)$. The *singular cohomology* $H^n(X, A; G)$ is the cohomology of this complex, and $H^n(X; G) = H^n(X, \emptyset; G)$. A map of pairs f induces $f^{\#} = \operatorname{Hom}(f_{\#}, G)$ and $f^*\colon H^n(Y, B; G) \to H^n(X, A; G)$, contravariantly. Reduced cohomology $\tilde{H}^n(X; G)$ is obtained by dualising the augmented chain complex. We write $H^n(X)$ for $H^n(X; \mathbb{Z})$. The *Kronecker pairing* $\langle -, - \rangle\colon H^n(X, A; G) \times H_n(X, A) \to G$ is $\langle [\varphi], [c] \rangle = \varphi(c)$.

Theorem 22.2.2. *1. Homotopic maps of pairs induce the same map on cohomology.*

2. *For $B \subseteq A \subseteq X$ there is a natural long exact sequence $\cdots \to H^n(X, A; G) \to H^n(X, B; G) \to H^n(A, B; G) \xrightarrow{\delta} H^{n+1}(X, A; G) \to \cdots$, and $\langle \delta\alpha, c \rangle = \langle \alpha, \partial c \rangle$ for $\alpha \in H^n(A; G)$ and $c \in H_{n+1}(X, A)$.*

3. *(Excision) If $Z \subseteq A \subseteq X$ with $\overline{Z} \subseteq \operatorname{int} A$, then $H^n(X, A; G) \to H^n(X \setminus Z, A \setminus Z; G)$ is an isomorphism.*

4. *(Mayer–Vietoris) If $\operatorname{int} A \cup \operatorname{int} B = X$, there is a long exact sequence $\cdots \to H^n(X; G) \to H^n(A; G) \oplus H^n(B; G) \to H^n(A \cap B; G) \to H^{n+1}(X; G) \to \cdots$.*

5. *$H^0(X;G)$ is the group of functions from the set of path components of X to G.*

Proof. Applying $\mathrm{Hom}(-,G)$ turns chain homotopies into cochain homotopies, which gives (1) from Theorem 21.3.1. The sequences $0 \to C_n(A,B) \to C_n(X,B) \to C_n(X,A) \to 0$ and $0 \to C_n(A\cap B) \to C_n(A)\oplus C_n(B) \to C_n^{\{A,B\}}(X) \to 0$ consist of free abelian groups and split degreewise, since the quotients are free on the simplices not in the subspace. So they remain exact after $\mathrm{Hom}(-,G)$, and Theorem 15.4.3 gives the long exact sequences. The connecting map sends $[\varphi]$ to the class of $\delta\tilde{\varphi}$ for an extension $\tilde{\varphi}$ of φ to X, which gives the formula for the pairing. The chain homotopy equivalence $C^{\mathcal{U}}(X) \to C(X)$ of Proposition 21.5.3 dualises to a cochain homotopy equivalence, which gives (3) as in Theorem 21.5.4 and allows the replacement of $H^n(\mathrm{Hom}(C^{\{A,B\}}(X),G))$ by $H^n(X;G)$ in (4). For (5), a 0-cocycle is a function φ on points with $\varphi(\gamma(1)) - \varphi(\gamma(0)) = 0$ for every path γ. □

Theorem 22.2.3 (Universal coefficients)**.** *There is a natural short exact sequence*

$$0 \to \mathrm{Ext}^1_{\mathbb{Z}}(H_{n-1}(X,A),G) \to H^n(X,A;G) \to \mathrm{Hom}(H_n(X,A),G) \to 0,$$

where the second map is $\alpha \mapsto \langle \alpha, - \rangle$. It splits, non-naturally. If $G = F$ is a field and $A = \emptyset$, then $H^n(X;F) \cong \mathrm{Hom}_F(H_n(X;F),F)$.

Proof. The first statement is Theorem 15.9.2 for the free complex $C(X,A)$. For a field, $\mathrm{Hom}_{\mathbb{Z}}(C_n(X),F) = \mathrm{Hom}_F(C_n(X)\otimes F, F)$, and $\mathrm{Hom}_F(-,F)$ is exact, so it commutes with taking cohomology. □

Lemma 22.2.4. $\mathrm{Ext}^1_{\mathbb{Z}}(\mathbb{Z},G) = 0$ *and* $\mathrm{Ext}^1_{\mathbb{Z}}(\mathbb{Z}/m\mathbb{Z},G) \cong G/mG$*;* $\mathrm{Ext}^1_{\mathbb{Z}}$ *commutes with finite direct sums. Hence, if $H_{n-1}(X)$ and $H_n(X)$ are finitely generated, $H^n(X;\mathbb{Z}) \cong \mathbb{Z}^{b_n} \oplus T_{n-1}$, where b_n is the rank of $H_n(X)$ and T_{n-1} the torsion subgroup of $H_{n-1}(X)$.*

Proof. Use the projective resolution $0 \to \mathbb{Z} \xrightarrow{m} \mathbb{Z} \to \mathbb{Z}/m\mathbb{Z} \to 0$ and Theorem 15.8.2: $\mathrm{Ext}^1(\mathbb{Z}/m\mathbb{Z},G)$ is the cokernel of $G \xrightarrow{m} G$. Additivity follows from additivity of Hom and of derived functors. For the last statement, write $H_n(X) \cong \mathbb{Z}^{b_n} \oplus T_n$ and $H_{n-1}(X) \cong \mathbb{Z}^{b_{n-1}} \oplus T_{n-1}$ with T_n, T_{n-1} finite direct sums of groups $\mathbb{Z}/m\mathbb{Z}$ (Theorem 7.11.6). By the split universal coefficient sequence, $H^n(X) \cong \mathrm{Hom}(H_n(X),\mathbb{Z}) \oplus \mathrm{Ext}^1(H_{n-1}(X),\mathbb{Z})$; here $\mathrm{Hom}(\mathbb{Z}/m\mathbb{Z},\mathbb{Z}) = 0$ gives $\mathrm{Hom}(H_n(X),\mathbb{Z}) \cong \mathbb{Z}^{b_n}$, and $\mathrm{Ext}^1(\mathbb{Z}/m\mathbb{Z},\mathbb{Z}) \cong \mathbb{Z}/m\mathbb{Z}$ gives $\mathrm{Ext}^1(H_{n-1}(X),\mathbb{Z}) \cong T_{n-1}$. □

Example 22.2.5.

1. $\tilde{H}^k(S^n;G) \cong G$ for $k = n$ and 0 otherwise.
2. By Example 21.7.5 and Lemma 22.2.4, $H^k(\mathbb{RP}^n;\mathbb{Z})$ is $\mathbb{Z}$ for $k = 0$, $\mathbb{Z}/2\mathbb{Z}$ for k even with $0 < k \le n$, $\mathbb{Z}$ for $k = n$ odd, and 0 otherwise: torsion moves up one degree compared with homology. With coefficients in $\mathbb{F}_2$, $H^k(\mathbb{RP}^n;\mathbb{F}_2) \cong \mathbb{F}_2$ for $0 \le k \le n$.

Theorem 22.2.6 (Cellular cohomology)**.** *For a CW complex X, $H^n(X;G)$ is isomorphic to the cohomology of the complex* $\mathrm{Hom}(C^{CW}_\bullet(X),G)$ *with the transposed differentials.*

Proof. By the universal coefficient theorem and Lemma 21.7.1: $H^k(X^n,X^{n-1};G)$ is $\mathrm{Hom}(C^{CW}_n(X),G)$ for $k = n$ and 0 otherwise; $H^k(X^n;G) = 0$ for $k > n$, because $H_k(X^n) = 0$ for $k > n$ and $H_n(X^n)$ is a subgroup of the free group $C^{CW}_n(X)$, hence free (Proposition 15.8.5). From the long exact sequence of (X,X^n) and Lemma 21.7.1(3), $H_k(X,X^n) = 0$ for $k \le n$, hence $H^k(X,X^n;G) = 0$ for $k \le n$ and $H^k(X;G) \to H^k(X^n;G)$ is an isomorphism for $k < n$. The proof of Theorem 21.7.3 now applies with all arrows reversed. The coboundary $H^n(X^n,X^{n-1}) \to H^n(X^n) \to H^{n+1}(X^{n+1},X^n)$ is the transpose of d_{n+1} by the formula $\langle \delta\alpha, c\rangle = \langle \alpha, \partial c\rangle$. □

Corollary 22.2.7. *Let X be a CW complex with finitely many cells in each dimension and no cells of odd dimension. Then $H^k(X;G) = 0$ for k odd, and $H^k(X;G) \cong G^{c_k}$ for k even, where c_k is the number of k-cells. The same holds for homology, and $\chi(X) = \sum_k c_k$ when X is finite.*

Proof. The cellular chain complex has $C_k^{CW}(X) = 0$ for k odd, so all its differentials vanish, being maps into or out of zero groups. By Theorem 22.2.6 the cohomology is $\mathrm{Hom}(C_k^{CW}(X), G) = \mathrm{Hom}(\mathbb{Z}^{c_k}, G) = G^{c_k}$ in each even degree k, and 0 in odd degrees; the homology statement is Theorem 21.7.3. The Euler characteristic is the alternating sum of the ranks. □

Example 22.2.8. $\mathbb{CP}^n$ has one cell in each even dimension $0, 2, \dots, 2n$ (Example 21.7.5), so $H^{2k}(\mathbb{CP}^n;\mathbb{Z}) \cong \mathbb{Z}$ for $0 \le k \le n$ and all other groups vanish, and $\chi(\mathbb{CP}^n) = n+1$. The product $S^2 \times S^2$, with cells e^0, $e^2 \times e^0$, $e^0 \times e^2$, $e^2 \times e^2$, has $H^0 = H^4 = \mathbb{Z}$ and $H^2 = \mathbb{Z}^2$. For $\mathbb{RP}^n$, which has one cell in each dimension $\le n$, the corollary does not apply, and indeed its cohomology has torsion (Example 22.2.5).

22.3 The cup product

Definition 22.3.1. For $\varphi \in C^k(X;R)$ and $\psi \in C^l(X;R)$, the *cup product* $\varphi \smile \psi \in C^{k+l}(X;R)$ is

$$(\varphi \smile \psi)(\sigma) = \varphi(\sigma \circ [e_0, \dots, e_k]) \cdot \psi(\sigma \circ [e_k, \dots, e_{k+l}]),$$

the product being taken in R: the "front k-face" times the "back l-face". We write $\sigma|[e_0, \dots, e_k]$ for $\sigma \circ [e_0, \dots, e_k]$.

Lemma 22.3.2. $\delta(\varphi \smile \psi) = \delta\varphi \smile \psi + (-1)^k \varphi \smile \delta\psi$. *The cup product of cochains is associative, R-bilinear, has unit the 0-cochain 1 with value 1 on every point, and is natural: $f^\#(\varphi \smile \psi) = f^\#\varphi \smile f^\#\psi$.*

Proof. Let $\sigma\colon \Delta^{k+l+1} \to X$ and $n = k + l + 1$. Then

$$(\delta\varphi \smile \psi)(\sigma) = \sum_{i=0}^{k+1} (-1)^i \varphi(\sigma|[e_0, \dots, \widehat{e_i}, \dots, e_{k+1}])\psi(\sigma|[e_{k+1}, \dots, e_n]),$$

$$(-1)^k(\varphi \smile \delta\psi)(\sigma) = \sum_{i=k}^{n} (-1)^i \varphi(\sigma|[e_0, \dots, e_k])\psi(\sigma|[e_k, \dots, \widehat{e_i}, \dots, e_n]).$$

The term $i = k+1$ of the first sum cancels the term $i = k$ of the second. The remaining terms are $\sum_i (-1)^i(\varphi \smile \psi)(\sigma|[e_0, \dots, \widehat{e_i}, \dots, e_n])$, which is $(\varphi \smile \psi)(\partial\sigma) = \delta(\varphi \smile \psi)(\sigma)$. The other statements are immediate from the definition. □

Definition 22.3.3. By Lemma 22.3.2, the cup product of two cocycles is a cocycle, and the product of a cocycle and a coboundary is a coboundary. It therefore induces $\smile\colon H^k(X;R) \times H^l(X;R) \to H^{k+l}(X;R)$, making $H^*(X;R) = \bigoplus_k H^k(X;R)$ an associative graded R-algebra with unit, the *cohomology ring*, and f^* a homomorphism of graded rings. If φ vanishes on chains in A so does $\varphi \smile \psi$, which gives a product $H^k(X, A;R) \times H^l(X;R) \to H^{k+l}(X, A;R)$.

Theorem 22.3.4 (Graded commutativity)**.** *For $\alpha \in H^k(X;R)$ and $\beta \in H^l(X;R)$, $\alpha \smile \beta = (-1)^{kl}\beta \smile \alpha$.*

Sketch of proof. Let $\bar\sigma = \sigma \circ [e_n, \dots, e_0]$ be σ with its vertices in reverse order, and $\rho(\sigma) = \varepsilon_n \bar\sigma$ with $\varepsilon_n = (-1)^{n(n+1)/2}$. A direct computation shows that ρ is a chain map and that $\rho^\# \varphi \smile \rho^\# \psi = (-1)^{kl} \rho^\#(\psi \smile \varphi)$, using $\varepsilon_{k+l} = (-1)^{kl} \varepsilon_k \varepsilon_l$. The omitted verification is that ρ is chain homotopic to the identity, by the homotopy $P(\sigma) = \sum_i (-1)^i \varepsilon_{n-i}\, \sigma \circ \pi \circ [v_0, \dots, v_i, w_n, \dots, w_i]$, where $v_j = (e_j, 0)$ and $w_j = (e_j, 1)$ are the vertices of $\Delta^n \times I$ and $\pi\colon \Delta^n \times I \to \Delta^n$ is the projection; see [Hat02, Theorem 3.14]. Then $\rho^* = \mathrm{id}$ on cohomology, and the formula follows. □

Example 22.3.5. For a wedge $X \vee Y$ of CW complexes (at 0-cells), the inclusions induce an isomorphism of rings $\tilde H^*(X \vee Y; R) \cong \tilde H^*(X; R) \times \tilde H^*(Y; R)$, where products between the two factors vanish: the isomorphism of groups follows from Exercise 21.10.3 and the universal coefficient theorem, and it is induced by the restrictions to X and Y, which are ring homomorphisms. In particular all cup products $\tilde H^k(S^m) \times \tilde H^l(S^m) \to \tilde H^{k+l}(S^m)$ vanish, for degree reasons.

22.4 The Künneth formula

Definition 22.4.1. The *cross product* of $a \in H^k(X; R)$ and $b \in H^l(Y; R)$ is $a \times b = p_X^*(a) \smile p_Y^*(b) \in H^{k+l}(X \times Y; R)$, where p_X, p_Y are the projections. It is R-bilinear and induces $H^*(X; R) \otimes_R H^*(Y; R) \to H^*(X \times Y; R)$, a ring homomorphism for the product $(a \otimes b)(c \otimes d) = (-1)^{|b||c|} ac \otimes bd$ on the tensor product.

Theorem 22.4.2 (Künneth formula)**.** *Let X and Y be CW complexes such that $H^k(Y; R)$ is a finitely generated free R-module for every k (for instance R a field and Y a finite complex). Then the cross product $H^*(X; R) \otimes_R H^*(Y; R) \to H^*(X \times Y; R)$ is an isomorphism of graded rings.*

This is [Hat02, Theorem 3.15]. The ring homomorphism property follows from graded commutativity: $(a \times b)(c \times d) = p_X^* a\, p_Y^* b\, p_X^* c\, p_Y^* d = (-1)^{|b||c|} p_X^*(ac)\, p_Y^*(bd)$. The homology Künneth formula for fields, and the Eilenberg–Zilber theorem $C_\bullet(X \times Y) \simeq C_\bullet(X) \otimes C_\bullet(Y)$ underlying it, are in [Hat02, Section 3.B].

Example 22.4.3. $H^*(S^1; \mathbb{Z}) = \Lambda_{\mathbb{Z}}[x]$ with $|x| = 1$ (an exterior algebra, as $x^2 \in H^2(S^1) = 0$). By induction and the Künneth formula, the cohomology ring of the torus $T^n = (S^1)^n$ is the exterior algebra $\Lambda_{\mathbb{Z}}[x_1, \dots, x_n]$ with $|x_i| = 1$, so $H^k(T^n) \cong \mathbb{Z}^{\binom{n}{k}}$. Similarly $H^*(S^2 \times S^2; \mathbb{Z}) = \mathbb{Z}[a, b]/(a^2, b^2)$ with $|a| = |b| = 2$.

22.5 Cohomology rings of projective spaces

Theorem 22.5.1. *$H^*(\mathbb{RP}^n; \mathbb{F}_2) \cong \mathbb{F}_2[\alpha]/(\alpha^{n+1})$ with $|\alpha| = 1$, and $H^*(\mathbb{CP}^n; \mathbb{Z}) \cong \mathbb{Z}[\alpha]/(\alpha^{n+1})$ with $|\alpha| = 2$. Also $H^*(\mathbb{RP}^\infty; \mathbb{F}_2) = \mathbb{F}_2[\alpha]$ and $H^*(\mathbb{CP}^\infty; \mathbb{Z}) = \mathbb{Z}[\alpha]$.*

This is [Hat02, Theorem 3.12]; the additive structure was computed above, and the content is that the generator in each degree is a power of α. A proof via Poincaré duality is given in Chapter 23.

Example 22.5.2. $\mathbb{CP}^2$ and $S^2 \vee S^4$ have the same homology and cohomology groups ($\mathbb{Z}$ in degrees $0, 2, 4$), but they are not homotopy equivalent: in $H^*(\mathbb{CP}^2)$ the square of a generator of H^2 generates H^4, whereas in $H^*(S^2 \vee S^4)$ it is zero by Example 22.3.5. Likewise $S^2 \times S^2$ and $S^2 \vee S^2 \vee S^4$ have the same groups but different rings.

Corollary 22.5.3 (Borsuk–Ulam)**.** *There is no map $g\colon S^n \to S^{n-1}$ with $g(-x) = -g(x)$ for all x. Consequently every map $f\colon S^n \to \mathbb{R}^n$ identifies some pair of antipodal points.*

Proof. For $n = 1$ an odd map $S^1 \to S^0$ cannot exist, since its image would be a single point. Let $n \geq 2$ and suppose g exists; it induces $\bar{g}\colon \mathbb{RP}^n \to \mathbb{RP}^{n-1}$. For a path-connected space X, the universal coefficient theorem and Theorem 21.9.1 give $H^1(X;\mathbb{F}_2) \cong \mathrm{Hom}(H_1(X),\mathbb{F}_2) \cong \mathrm{Hom}(\pi_1(X),\mathbb{F}_2)$, naturally. For $m \geq 1$ let $w_m\colon \pi_1(\mathbb{RP}^m) \to \mathbb{F}_2$ be the monodromy of the two-sheeted covering $S^m \to \mathbb{RP}^m$ (Example 19.4.10): $w_m[\gamma] = 0$ if and only if the lifts of γ are loops. It is a homomorphism (Corollary 19.4.4(3)) and nonzero. Since $\pi_1(\mathbb{RP}^n) \cong \mathbb{Z}/2\mathbb{Z}$, w_n corresponds to the generator α of $H^1(\mathbb{RP}^n;\mathbb{F}_2)$, and $\pi_1(\mathbb{RP}^n)$ is generated by the image of a path γ in S^n from x to $-x$. Its image under $\bar{g}$ is the image of the path $g \circ \gamma$ from $g(x)$ to $-g(x)$, whose lift is not a loop; so $w_{n-1}(\bar{g}_*[\gamma]) = 1 = w_n[\gamma]$ and $\bar{g}^*(w_{n-1}) = \alpha$. Then $\bar{g}^*(w_{n-1}^n) = \alpha^n \neq 0$ by Theorem 22.5.1, but $w_{n-1}^n \in H^n(\mathbb{RP}^{n-1};\mathbb{F}_2) = 0$, a contradiction. If $f(x) \neq f(-x)$ for all x, then $g(x) = (f(x) - f(-x))/\|f(x) - f(-x)\|$ is an odd map $S^n \to S^{n-1}$. □

22.6 Cup length and coverings by contractible sets

Lemma 22.6.1. *Let A, B be open subsets of X. The cup product of cochains induces a product $H^k(X,A;R) \times H^l(X,B;R) \to H^{k+l}(X,A\cup B;R)$, compatible with the absolute cup product under the maps $H^\bullet(X,C;R) \to H^\bullet(X;R)$ for $C = A, B, A \cup B$.*

Proof. If φ vanishes on simplices in A and ψ on simplices in B, then $\varphi \smile \psi$ vanishes on simplices in A (because of its front face) and on simplices in B (because of its back face), hence on the subcomplex $C(A) + C(B) \subseteq C(A \cup B)$. By Lemma 22.3.2, this gives a product with values in the cohomology of $\mathrm{Hom}(C(X)/(C(A) + C(B)), R)$. It remains to identify this cohomology with $H^\bullet(X, A \cup B; R)$. The inclusion $C(A) + C(B) \to C(A \cup B)$ is a chain homotopy equivalence by Proposition 21.5.3, applied to the open cover $\{A, B\}$ of $A \cup B$, so it induces isomorphisms on cohomology with coefficients in R. The sequences $0 \to C(A) + C(B) \to C(X) \to C(X)/(C(A) + C(B)) \to 0$ and $0 \to C(A \cup B) \to C(X) \to C(X, A \cup B) \to 0$ split degreewise, the quotients being free on the simplices not in the subcomplex, so they give long exact cohomology sequences after applying $\mathrm{Hom}(-, R)$, and the inclusions give a map between them. The five lemma (Lemma 15.4.2) shows that $H^\bullet(X, A\cup B; R) \to H^\bullet(\mathrm{Hom}(C(X)/(C(A)+C(B)), R))$ is an isomorphism. Compatibility with the absolute product holds on cochains. □

Proposition 22.6.2. *Let X be covered by open sets $U_1, \ldots, U_n$ such that each inclusion $U_i \to X$ is homotopic to a constant map. Then $\alpha_1 \smile \cdots \smile \alpha_n = 0$ for all $\alpha_i \in H^{k_i}(X;R)$ with $k_i \geq 1$.*

Proof. The restriction $H^k(X;R) \to H^k(U_i;R)$ is induced by the inclusion, which is homotopic to a map factoring through a point, so it is zero for $k \geq 1$, as $H^k(\mathrm{pt};R) = 0$ (Theorem 22.2.2(1)). By the long exact sequence of the pair (X, U_i), each α_i lifts to $\tilde{\alpha}_i \in H^{k_i}(X, U_i; R)$. By Lemma 22.6.1, applied $n-1$ times, $\tilde{\alpha}_1 \smile \cdots \smile \tilde{\alpha}_n$ lies in $H^\bullet(X, U_1 \cup \cdots \cup U_n; R) = H^\bullet(X, X; R) = 0$ and maps to $\alpha_1 \smile \cdots \smile \alpha_n$. □

Corollary 22.6.3.

1. *The torus T^n cannot be covered by n open sets that are contractible in T^n, but it can be covered by $n+1$ of them.*
2. *$\mathbb{CP}^n$ cannot be covered by n open sets contractible in $\mathbb{CP}^n$, and it is covered by the $n+1$ standard affine charts, each homeomorphic to $\mathbb{C}^n$.*
3. *$\mathbb{RP}^n$ cannot be covered by n open sets contractible in $\mathbb{RP}^n$.*

Proof. By Proposition 22.6.2 it suffices to exhibit n classes of positive degree with nonzero product: $x_1 \smile \cdots \smile x_n$ generates $H^n(T^n)$ (Example 22.4.3), and $\alpha^n \neq 0$ in $H^{2n}(\mathbb{CP}^n;\mathbb{Z})$ and in $H^n(\mathbb{RP}^n;\mathbb{F}_2)$ (Theorem 22.5.1). For the covering of $T^n = \mathbb{R}^n/\mathbb{Z}^n$ by $n+1$ sets, let U_j,

$0 \le j \le n$, be the image of the open set of points $x \in \mathbb{R}^n$ whose coordinates avoid the interval $[\frac{j}{n+1} + \frac{1}{4(n+1)}, \frac{j}{n+1} + \frac{3}{4(n+1)}]$ modulo 1: each coordinate then ranges in an open interval of $\mathbb{R}/\mathbb{Z}$, so U_j is homeomorphic to an open cube, which is contractible. Every x lies in some U_j, because its n coordinates can meet at most n of the $n+1$ disjoint intervals. □

Remark 22.6.4. The least m such that X is covered by $m+1$ open sets contractible in X is the *Lusternik–Schnirelmann category* of X. Proposition 22.6.2 bounds it from below by the *cup length*, the largest number of classes of positive degree with nonzero product. By Corollary 22.6.3 the category of T^n is n. Lusternik and Schnirelmann introduced this invariant to bound from below the number of critical points of smooth functions on closed manifolds.

22.7 The cap product

Definition 22.7.1. For $\sigma\colon \Delta^n \to X$ and $\varphi \in C^k(X;R)$ with $k \le n$, the *cap product* is

$$\sigma \frown \varphi = \varphi(\sigma|[e_0,\dots,e_k]) \cdot \sigma|[e_k,\dots,e_n] \in C_{n-k}(X;R),$$

extended R-linearly to $C_n(X;R) = C_n(X) \otimes R$.

Proposition 22.7.2. *1. $\partial(\sigma \frown \varphi) = (-1)^k(\partial\sigma \frown \varphi - \sigma \frown \delta\varphi)$, so the cap product induces $\frown\colon H_n(X;R) \times H^k(X;R) \to H_{n-k}(X;R)$, and relative versions $H_n(X,A;R) \times H^k(X;R) \to H_{n-k}(X,A;R)$ and $H_n(X,A;R) \times H^k(X,A;R) \to H_{n-k}(X;R)$.*

2. (Naturality) $f_*(c) \frown \varphi = f_*(c \frown f^*\varphi)$ for $f\colon X \to Y$, $c \in H_n(X;R)$ and $\varphi \in H^k(Y;R)$.

3. $\psi(c \frown \varphi) = (\varphi \smile \psi)(c)$ for $\psi \in C^{n-k}(X;R)$, and $(c \frown \varphi) \frown \psi = c \frown (\varphi \smile \psi)$.

Proof. (1) We have $\partial(\sigma \frown \varphi) = \sum_{i\ge k}(-1)^{i-k}\varphi(\sigma|[e_0,\dots,e_k])\,\sigma|[e_k,\dots,\widehat{e_i},\dots,e_n]$, while

$$\partial\sigma \frown \varphi = \sum_{i\le k}(-1)^i\varphi(\sigma|[e_0,\dots,\widehat{e_i},\dots,e_{k+1}])\,\sigma|[e_{k+1},\dots,e_n] + \sum_{i\ge k+1}(-1)^i\varphi(\sigma|[e_0,\dots,e_k])\,\sigma|[e_k,\dots,\widehat{e_i},\dots,e_n]$$

and $\sigma \frown \delta\varphi = \sum_{i\le k+1}(-1)^i\varphi(\sigma|[e_0,\dots,\widehat{e_i},\dots,e_{k+1}])\,\sigma|[e_{k+1},\dots,e_n]$. Subtracting, what remains is the second sum together with the term $-(-1)^{k+1}\varphi(\sigma|[e_0,\dots,e_k])\,\sigma|[e_{k+1},\dots,e_n]$, which is the term $i=k$; this is $(-1)^k\partial(\sigma \frown \varphi)$. Hence cycle $\frown$ cocycle is a cycle, boundary $\frown$ cocycle and cycle $\frown$ coboundary are boundaries. For the relative versions, $\sigma \frown \varphi$ lies in $C(A)$ if σ does, and vanishes if φ vanishes on A and σ lies in A. (2) and (3) are immediate from the definitions: $\psi(\sigma \frown \varphi) = \varphi(\sigma|[e_0,\dots,e_k])\psi(\sigma|[e_k,\dots,e_n]) = (\varphi \smile \psi)(\sigma)$. □

Remark 22.7.3. For a closed oriented n-manifold M with fundamental class $[M] \in H_n(M;\mathbb{Z})$, the map $H^k(M;R) \to H_{n-k}(M;R)$, $\alpha \mapsto [M] \frown \alpha$, is an isomorphism: this is Poincaré duality (Chapter 23). Combined with Proposition 22.7.2(3) it shows that the cup product pairing $H^k(M;F) \times H^{n-k}(M;F) \to F$, $(\alpha,\beta) \mapsto \langle \alpha \smile \beta, [M]\rangle$, is nondegenerate over a field F.

22.8 Exercises

Exercise 22.8.1. Compute $H^k(\mathbb{RP}^n;\mathbb{Z}/4\mathbb{Z})$ from the cellular cochain complex, and check the result with the universal coefficient theorem.

Solution. The cellular cochain complex is $\mathbb{Z}/4 \to \mathbb{Z}/4 \to \cdots$ with differential $\mathrm{Hom}(d_{k+1},\mathbb{Z}/4)$, multiplication by $1+(-1)^{k+1}$: zero out of even degrees and multiplication by 2 out of odd degrees. So $H^0 = \mathbb{Z}/4$; for $0 < k < n$, $H^k \cong \mathbb{Z}/2$ (for k odd the kernel of 2 is $2\mathbb{Z}/4$ and the image of the previous zero map is 0; for k even the kernel is all of $\mathbb{Z}/4$ and the image is $2\mathbb{Z}/4$);

and H^n is $\mathbb{Z}/4$ for n odd and $\mathbb{Z}/2$ for n even. With universal coefficients, for $0 < k < n$ odd: $\mathrm{Hom}(\mathbb{Z}/2, \mathbb{Z}/4) \oplus \mathrm{Ext}(0, \mathbb{Z}/4) = \mathbb{Z}/2$; for k even: $\mathrm{Hom}(0, \mathbb{Z}/4) \oplus \mathrm{Ext}(\mathbb{Z}/2, \mathbb{Z}/4) = \mathbb{Z}/4/2\mathbb{Z}/4 = \mathbb{Z}/2$. □

Exercise 22.8.2. Let Σ_g be the closed orientable surface of genus g. Using the map $\Sigma_g \to \bigvee_{i=1}^{g} T^2$ collapsing $g-1$ circles, show that $H^1(\Sigma_g) \cong \mathbb{Z}^{2g}$ has a basis a_i, b_i with $a_i \smile b_i = -b_i \smile a_i$ a generator of $H^2(\Sigma_g) \cong \mathbb{Z}$, and all other products of basis elements zero.

Exercise 22.8.3. For a map $f : S^{2n-1} \to S^n$ with $n \geq 2$ let $X_f = S^n \cup_f D^{2n}$. Show that $H^n(X_f) \cong \mathbb{Z} \cdot a$ and $H^{2n}(X_f) \cong \mathbb{Z} \cdot b$ and define the Hopf invariant $h(f)$ by $a^2 = h(f)b$. Show that $h(f) = 0$ if n is odd, and that h of the Hopf map $S^3 \to S^2$ is ± 1, using $X_f = \mathbb{CP}^2$.

Exercise 22.8.4. Show that $S^2 \vee S^4$ is not a retract of $\mathbb{CP}^2$, even up to homotopy: there are no maps $i : S^2 \vee S^4 \to \mathbb{CP}^2$ and $r : \mathbb{CP}^2 \to S^2 \vee S^4$ with $ri \simeq \mathrm{id}$. Show also that there is no map $\mathbb{CP}^2 \to S^2$ inducing an isomorphism on H^2.

Solution. A map $f : \mathbb{CP}^2 \to S^2$ with f^* an isomorphism on H^2 would give $f^*(x)^2 = f^*(x^2) = 0$ for a generator x of $H^2(S^2)$, while $f^*(x)$ generates $H^2(\mathbb{CP}^2)$ and its square generates $H^4(\mathbb{CP}^2)$. If $S^2 \vee S^4 \xrightarrow{i} \mathbb{CP}^2 \xrightarrow{r} S^2 \vee S^4$ composed to the identity (up to homotopy), then i^* would be surjective, and r^* injective; a generator $u \in H^2(S^2 \vee S^4)$ would satisfy $r^*(u)^2 = r^*(u^2) = 0$ with $r^*(u) = \pm$ a generator of $H^2(\mathbb{CP}^2)$ (as r^* is injective on $H^2 \cong \mathbb{Z}$ and $i^* r^* = \mathrm{id}$ forces r^* to be split injective), contradicting $\alpha^2 \neq 0$. □

Chapter 23

Topological Manifolds and Poincaré Duality

23.1 Introduction

A closed oriented n-manifold M has a fundamental class $[M] \in H_n(M;\mathbb{Z})$, and capping with it is an isomorphism $H^k(M;R) \cong H_{n-k}(M;R)$ (Theorem 23.6.2). Duality is what turns a closed oriented submanifold, or a complex subvariety, of dimension d into a cohomology class of degree $n-d$, and it makes the cup product pairing between complementary degrees nondegenerate. We follow [Hat02, Section 3.3].

Prerequisites. Chapter 22 (Singular Cohomology).

On the way to the Hodge conjecture. Needed: orientations, the fundamental class, cohomology with compact supports and Poincaré duality; Borel–Moore homology (Section 23.8) gives the fundamental classes of singular subvarieties used for the cycle class map. The other dualities (Section 23.7) can be postponed.

For a space X and $A \subseteq X$ we write $H_i(X \mid A;R) = H_i(X, X \setminus A;R)$ and $H^i(X \mid A;R) = H^i(X, X \setminus A;R)$, and $H_i(X \mid x)$ for $A = \{x\}$.

23.2 Topological manifolds

Definition 23.2.1. A *topological n-manifold* is a Hausdorff, second countable space in which every point has an open neighbourhood homeomorphic to $\mathbb{R}^n$ (Definition 20.5.1, where the role of each axiom is discussed). A *chart* is such a neighbourhood with a homeomorphism to $\mathbb{R}^n$. A manifold is *closed* if it is compact. A *manifold with boundary* is defined in the same way with neighbourhoods homeomorphic to open subsets of the half-space $\{x \in \mathbb{R}^n : x_n \geq 0\}$; its *boundary* ∂M consists of the points that correspond to points with $x_n = 0$.

Lemma 23.2.2. *For a point x of an n-manifold M, $H_i(M \mid x;R) \cong R$ for $i = n$ and 0 otherwise. In particular the dimension of a nonempty manifold is well defined. For an open ball B of finite radius in a chart and $x \in B$, the restriction $H_i(M \mid B;R) \to H_i(M \mid x;R)$ is an isomorphism.*

Proof. Let $V \ni x$ be a chart. The closure of B in V is compact, hence closed in M, so excision of $M \setminus V$ gives $H_i(M \mid B) \cong H_i(V \mid B) \cong H_i(\mathbb{R}^n \mid B)$, and likewise for x. Both $\mathbb{R}^n \setminus B$ and $\mathbb{R}^n \setminus \{x\}$ deformation retract onto a sphere centred at x of radius larger than that of B, by radial projection from x; so the restriction is an isomorphism, and $H_i(\mathbb{R}^n \mid x) \cong \tilde{H}_{i-1}(\mathbb{R}^n \setminus \{x\}) \cong \tilde{H}_{i-1}(S^{n-1};R)$ by the long exact sequence. The dimension is well defined by Corollary 21.6.7(3). □

Example 23.2.3. $\mathbb{R}^n$, open subsets of manifolds, S^n (charts by stereographic projection), and products of manifolds (of dimension $m+n$) are manifolds; hence so is the torus T^n. The projective spaces $\mathbb{RP}^n$ and $\mathbb{CP}^n$ are closed manifolds of dimensions n and $2n$ (Chapter 44), and so are the surfaces Σ_g. The disc D^n is a manifold with boundary S^{n-1}. The line with two origins (Counterexample 18.4.12) is locally Euclidean but not Hausdorff.

23.3 Orientations

Definition 23.3.1. Let M be an n-manifold. A *coordinate ball* is an open ball of finite radius in a chart. Let M_R be the set of pairs (x, α) with $x \in M$ and $\alpha \in H_n(M \mid x; R)$, with $p(x, \alpha) = x$. For a coordinate ball B and $\alpha_B \in H_n(M \mid B; R)$ let $U(\alpha_B)$ be the set of pairs (x, α_x) with $x \in B$ and α_x the image of α_B. An *R-orientation* of M is a continuous section $x \mapsto \mu_x$ of p such that each μ_x generates $H_n(M \mid x; R) \cong R$ as an R-module. A $\mathbb{Z}$-orientation is an *orientation*, and M is *(R-)orientable* if it has one. The *orientation double covering* $\tilde{M} \subseteq M_{\mathbb{Z}}$ consists of the pairs (x, α) with α a generator of $H_n(M \mid x; \mathbb{Z}) \cong \mathbb{Z}$.

Proposition 23.3.2. *The sets $U(\alpha_B)$ form a basis of a topology on M_R for which p is a covering map, and $\tilde{M} \to M$ is a two-sheeted covering. Let M be connected.*

1. *M is orientable if and only if $\tilde{M}$ has two components; then M has exactly two orientations.*
2. *If $\pi_1(M)$ has no subgroup of index 2, for instance if M is simply connected, then M is orientable.*
3. *M is $\mathbb{F}_2$-orientable, and an orientable manifold is R-orientable for every R.*

Proof. If $(x, \alpha) \in U(\alpha_B) \cap U(\beta_{B'})$, choose a coordinate ball $B'' \ni x$ inside $B \cap B'$. The images of α_B and $\beta_{B'}$ in $H_n(M \mid B'')$ both restrict to α, so they are equal by Lemma 23.2.2, and their U is contained in both sets. By the same lemma, p maps $U(\alpha_B)$ bijectively onto B, and $p^{-1}(B)$ is the disjoint union of the sets $U(\alpha_B)$, $\alpha_B \in H_n(M \mid B)$. For $B' \subseteq B$, $p^{-1}(B') \cap U(\alpha_B) = U(\alpha_{B'})$ with $\alpha_{B'}$ the restriction, and $p(U(\alpha_{B'})) = B'$; so $p|_{U(\alpha_B)}$ is a homeomorphism onto B, and p is a covering map. The generators form a union of sheets, two over each coordinate ball.

(1) A section s of a covering over a connected space has open image (near $s(x)$ it lies in one sheet, by continuity) and closed image (it is the set of points e with $s(p(e)) = e$, and the covering space is Hausdorff because M is and distinct sheets are disjoint open sets). So an orientation μ gives two components $\{\mu_x\}$ and $\{-\mu_x\}$ of $\tilde{M}$. Conversely, each sheet over a coordinate ball is connected and so lies in a single component; hence the number of points of a component C of $\tilde{M}$ over x is locally constant, hence constant; if $\tilde{M}$ is not connected it is 1, and $C \to M$ is a bijective covering map, hence a homeomorphism whose inverse is an orientation. The orientations are the sections of $\tilde{M}$, which are the inverses of the two components.

(2) If M is not orientable, $\tilde{M}$ is a connected two-sheeted covering, and $p_*\pi_1(\tilde{M})$ has index 2 by Corollary 19.4.4(3).

(3) $H_n(M \mid x; \mathbb{F}_2)$ has a unique generator, and $x \mapsto$ this generator is continuous since it lies in $U(\alpha_B)$ for the generator α_B. The coefficient homomorphism $\mathbb{Z} \to R$ induces a continuous map $M_{\mathbb{Z}} \to M_R$ over M sending generators to generators. □

23.4 The fundamental class

Lemma 23.4.1 (Relative Mayer–Vietoris)**.** *Let Y_1, Y_2 be open subsets of a space X. There are natural long exact sequences*

$$\cdots \to H_i(X, Y_1 \cap Y_2) \to H_i(X, Y_1) \oplus H_i(X, Y_2) \to H_i(X, Y_1 \cup Y_2) \to H_{i-1}(X, Y_1 \cap Y_2) \to \cdots$$

and $\cdots \to H^i(X, Y_1 \cup Y_2) \to H^i(X, Y_1) \oplus H^i(X, Y_2) \to H^i(X, Y_1 \cap Y_2) \to H^{i+1}(X, Y_1 \cup Y_2) \to \cdots$, *with any coefficients.*

Proof. The sequence $0 \to C(X)/C(Y_1 \cap Y_2) \to C(X)/C(Y_1) \oplus C(X)/C(Y_2) \to C(X)/(C(Y_1) + C(Y_2)) \to 0$, with maps $x \mapsto (x, -x)$ and $(x, y) \mapsto x + y$, is exact, because $C(Y_1) \cap C(Y_2) = C(Y_1 \cap Y_2)$. All terms are free abelian groups on sets of simplices, so it is degreewise split, and it remains exact after tensoring with R or applying $\mathrm{Hom}(-, R)$. The inclusion $C(Y_1) + C(Y_2) \to C(Y_1 \cup Y_2)$ is a quasi-isomorphism by Proposition 21.5.3 (the Y_i are open in $Y_1 \cup Y_2$), so by the five lemma the last complex computes $H_\bullet(X, Y_1 \cup Y_2)$; dually in cohomology. □

Lemma 23.4.2. *Let M be an n-manifold and $A \subseteq M$ compact.*

1. *If $x \mapsto \alpha_x$ is a continuous section of M_R over A, there is a unique $\alpha_A \in H_n(M \mid A; R)$ restricting to α_x for every $x \in A$.*
2. *$H_i(M \mid A; R) = 0$ for $i > n$.*

Proof. We omit R from the notation.

Step 1: if the lemma holds for compact A, B and $A \cap B$, it holds for $A \cup B$. Apply Lemma 23.4.1 with $Y_1 = M \setminus A$ and $Y_2 = M \setminus B$:

$$H_{i+1}(M \mid A \cap B) \to H_i(M \mid A \cup B) \xrightarrow{\Phi} H_i(M \mid A) \oplus H_i(M \mid B) \xrightarrow{\Psi} H_i(M \mid A \cap B),$$

where Φ consists of restrictions and Ψ is the difference of restrictions (up to the signs of the maps). For $i > n$ the outer terms vanish, giving (2). For $i = n$, Φ is injective, which gives uniqueness since restrictions to points factor through A or B. For existence, α_A and α_B restrict to elements of $H_n(M \mid A \cap B)$ that both restrict to α_x at every point, hence agree by uniqueness for $A \cap B$; so (α_A, α_B) lies in the kernel of Ψ and comes from some $\alpha_{A \cup B}$.

Step 2: $M = \mathbb{R}^n$ and A compact convex. Choose $x \in A$. Both $\mathbb{R}^n \setminus A$ and $\mathbb{R}^n \setminus \{x\}$ deformation retract onto a large sphere centred at x (moving points along rays from x, which leave the convex set A once), so $H_i(\mathbb{R}^n \mid A) \to H_i(\mathbb{R}^n \mid x)$ is an isomorphism, giving (2). For (1), let α_A be the element restricting to α_x. Choosing a coordinate ball $B \supseteq A$, the image of α_A at points of A is a continuous section (it comes from $H_n(\mathbb{R}^n \mid B) \cong H_n(\mathbb{R}^n \mid A)$). It agrees with the given section at x, so everywhere, since A is connected (Lemma 19.4.2).

Step 3: $M = \mathbb{R}^n$ and $A = A_1 \cup \cdots \cup A_m$ with each A_j compact convex. Induction on m using Step 1, since $(A_1 \cup \cdots \cup A_{m-1}) \cap A_m = \bigcup_{j<m} (A_j \cap A_m)$ is a union of $m - 1$ compact convex sets.

Step 4: $M = \mathbb{R}^n$ and A arbitrary compact. Let $\alpha \in H_i(\mathbb{R}^n \mid A)$ be represented by a chain z with ∂z a chain in $\mathbb{R}^n \setminus A$. The images of the simplices of ∂z form a compact set C disjoint from A. Cover $\mathbb{R}^n$ by the closed cubes of a grid of side smaller than the distance from A to C divided by $\sqrt{n}$, and let K be the union of those meeting A; then $A \subseteq K$, $K \cap C = \emptyset$, and z defines $\alpha_K \in H_i(\mathbb{R}^n \mid K)$ mapping to α. If $i > n$, $\alpha_K = 0$ by Step 3, so $\alpha = 0$. If $i = n$ and α restricts to 0 at every point of A, then α_K restricts to 0 at every point of K: each cube Q meets A, and the restriction of α_K to Q is determined by its value at a point of $Q \cap A$ (Step 2). By uniqueness in Step 3, $\alpha_K = 0$, so $\alpha = 0$; this is uniqueness. For existence, $M_R \to \mathbb{R}^n$ is a trivial covering $\mathbb{R}^n \times R$ (the restrictions from a large ball are isomorphisms), so a section over A is a locally constant function $A \to R$. By compactness it takes finitely many values, on disjoint compact sets A_r, which have positive distances from each other. Choose the grid so that twice the diameter of a cube is smaller than these distances. Then two cubes meeting different sets A_r are disjoint, so the unions K_r of the cubes meeting A_r are disjoint closed sets covering K, and the section extends to the locally constant function equal to r on K_r. Step 3 gives α_K, and its image in $H_n(\mathbb{R}^n \mid A)$ is the required class.

Step 5: general M. A compact $A \subseteq M$ is a finite union $A_1 \cup \cdots \cup A_m$ of compact sets each contained in a chart $V_j \cong \mathbb{R}^n$. By excision, $H_i(M \mid A_j) \cong H_i(V_j \mid A_j)$, compatibly with restrictions to points, so the lemma holds for sets contained in a chart by Step 4. Conclude by induction on m using Step 1, as $(A_1 \cup \cdots \cup A_{m-1}) \cap A_m$ is contained in the chart V_m. □

Theorem 23.4.3. *Let M be a closed connected n-manifold. Then $H_i(M;R) = 0$ for $i > n$, and the restriction $H_n(M;R) \to H_n(M \mid x;R) \cong R$ is injective for every x. Its image is R if M is R-orientable, and $\{r \in R : 2r = 0\}$ otherwise. If M is R-oriented by μ, the unique class $[M] \in H_n(M;R)$ restricting to μ_x for all x is the* fundamental class. *In particular $H_n(M;\mathbb{Z}) \cong \mathbb{Z}$ if M is orientable and 0 otherwise.*

Proof. Apply Lemma 23.4.2 with $A = M$, noting $H_i(M \mid M) = H_i(M)$: classes in $H_n(M)$ correspond to sections of M_R over M. A section over the connected space M is determined by its value at x, by Lemma 19.4.2. The set M_r of pairs (y, α) with $\alpha = \pm r\mu_y$ for a local generator μ_y is a union of components of M_R (it is open and closed, as can be checked on the sets $U(\alpha_B)$). If $r = -r$, then $M_r \to M$ is a homeomorphism, and there is a section with value r. If $r \neq -r$, then $M_r \cong \tilde{M}$ (identify $(y, \pm r\mu_y)$ with $(y, \pm\mu_y)$), which has a section if and only if M is orientable. Writing a general element of R as r times a generator gives the description of the image; for R-orientability, an R-orientation takes values $u\mu_y$ with u a unit, and $u \neq -u$ unless $2 = 0$ in R. □

23.5 Cohomology with compact supports

Lemma 23.5.1. *Let I be a directed set (Example 6.11.2). Colimits of diagrams $I \to \mathsf{Ab}$ exist, their underlying sets are the colimits of the underlying sets (Proposition 6.11.4), and they are exact: a colimit of exact sequences is exact. Hence they commute with homology of chain complexes. If $\phi\colon J \to I$ is an order-preserving map of directed sets with* cofinal *image (every $i \in I$ has some j with $i \leq \phi(j)$), then the induced map $\operatorname{colim}_J A_{\phi(j)} \to \operatorname{colim}_I A_i$ is an isomorphism.*

Proof. On the set $\operatorname{colim}_i A_i = (\coprod_i A_i)/\!\approx$, define $[a_i] + [b_j] = [u(a_i) + v(b_j)]$ after mapping both to a common k; this is well defined by Proposition 6.11.4 and makes the colimit an abelian group with the universal property in Ab. If $A_i \xrightarrow{f_i} B_i \xrightarrow{g_i} C_i$ are exact and $[b_i]$ maps to 0, then $g_i(b_i)$ becomes 0 in some C_k; replacing i by k we may assume $g_i(b_i) = 0$, so $b_i = f_i(a_i)$. So the colimit sequence is exact. Homology is kernel modulo image, hence preserved. For ϕ with cofinal image, every element of colim_I comes from some A_i and hence from $A_{\phi(j)}$ with $\phi(j) \geq i$. If an element of $A_{\phi(j)}$ vanishes in colim_I, it vanishes in some A_i with $i \geq \phi(j)$; choose j'' with $\phi(j'') \geq i$ and $j' \geq j, j''$; then it vanishes in $A_{\phi(j')}$, hence in colim_J. □

Definition 23.5.2. The *cohomology with compact supports* of a Hausdorff space X is $H^k_c(X;R) = \operatorname{colim}_K H^k(X \mid K;R)$, the colimit over the compact subsets $K \subseteq X$ directed by inclusion, along the restriction maps $H^k(X \mid K) \to H^k(X \mid L)$ for $K \subseteq L$. If X is compact, $H^k_c(X;R) = H^k(X;R)$. For an open $U \subseteq X$ and compact $K \subseteq U$, excision gives $H^k(U \mid K) \cong H^k(X \mid K)$; these isomorphisms induce a map $H^k_c(U;R) \to H^k_c(X;R)$ (extension by zero).

Example 23.5.3. The open balls centred at 0 are cofinal among compact subsets of $\mathbb{R}^n$, and for balls $B \subseteq B'$ the restriction $H^k(\mathbb{R}^n \mid B) \to H^k(\mathbb{R}^n \mid B')$ is an isomorphism, as in Lemma 23.2.2. So $H^k_c(\mathbb{R}^n;R) \cong R$ for $k = n$ and 0 otherwise, whereas $H^k(\mathbb{R}^n;R)$ is R in degree 0. Compactly supported cohomology is not a homotopy invariant.

Definition 23.5.4. Let M be an R-oriented n-manifold. For compact K let $\mu_K \in H_n(M \mid K;R)$ be the class of Lemma 23.4.2 restricting to the orientation. For $K \subseteq L$, μ_L restricts to μ_K, and naturality of the cap product $H_n(M \mid K) \times H^k(M \mid K) \to H_{n-k}(M)$ (Proposition 22.7.2) shows

that the maps $\varphi \mapsto \mu_K \frown \varphi$ are compatible. They induce the *duality map* $D_M \colon H_c^k(M;R) \to H_{n-k}(M;R)$. If M is closed, $D_M(\varphi) = [M] \frown \varphi$.

23.6 Poincaré duality

Lemma 23.6.1. *Let $M = U \cup V$ with U, V open. There are long exact Mayer–Vietoris sequences*

$$\cdots \to H_c^k(U \cap V) \to H_c^k(U) \oplus H_c^k(V) \to H_c^k(M) \to H_c^{k+1}(U \cap V) \to \cdots$$

and $\cdots \to H_{n-k}(U \cap V) \to H_{n-k}(U) \oplus H_{n-k}(V) \to H_{n-k}(M) \to H_{n-k-1}(U \cap V) \to \cdots$, and the duality maps $D_{U\cap V}$, $D_U \oplus D_V$, D_M form a diagram between them that commutes up to sign.

Proof. For compact $K \subseteq U$ and $L \subseteq V$, Lemma 23.4.1 with $Y_1 = M \setminus K$, $Y_2 = M \setminus L$ and excision give an exact sequence $\cdots \to H^k(U \cap V \mid K \cap L) \to H^k(U \mid K) \oplus H^k(V \mid L) \to H^k(M \mid K \cup L) \to H^{k+1}(U \cap V \mid K \cap L) \to \cdots$, natural in the pair (K, L). Take the colimit over such pairs (Lemma 23.5.1). The sets $K \cap L$ are cofinal among compact subsets of $U \cap V$ (take $K = L = C$), and the sets $K \cup L$ are cofinal among compact subsets of M: given compact $C \subseteq M$, the disjoint closed subsets $C \setminus V$ and $C \setminus U$ of the normal space C can be separated, giving an open $W \subseteq C$ with $C \setminus V \subseteq W \subseteq \overline{W} \subseteq U$, and then $K = \overline{W} \subseteq U$ and $L = C \setminus W \subseteq V$ are compact with $K \cup L = C$. This gives the first sequence; the second is Theorem 21.5.5. Commutativity of the squares not involving connecting maps is naturality of the cap product. Commutativity up to sign of the remaining square is [Hat02, Lemma 3.36]. □

Theorem 23.6.2 (Poincaré duality)**.** *For every R-oriented n-manifold M, the duality map $D_M \colon H_c^k(M;R) \to H_{n-k}(M;R)$ is an isomorphism for all k. In particular, if M is closed, $H^k(M;R) \to H_{n-k}(M;R)$, $\alpha \mapsto [M] \frown \alpha$, is an isomorphism.*

Proof. Open subsets of M inherit R-orientations, and the duality maps are compatible with the maps $H_c^k(U) \to H_c^k(M)$ and $H_{n-k}(U) \to H_{n-k}(M)$ by naturality of the cap product. We omit R.

(A) If D_U, D_V and $D_{U\cap V}$ are isomorphisms, so is $D_{U\cup V}$. By Lemma 23.6.1 and the five lemma (signs do not affect it).

(B) If $M = \bigcup_i U_i$ for a family of open sets directed by inclusion and all D_{U_i} are isomorphisms, so is D_M. Every compact subset of M lies in some U_i, so by cofinality $H_c^k(M) = \operatorname{colim}_i H_c^k(U_i)$. Every singular chain has compact image, so $H_{n-k}(M) = \operatorname{colim}_i H_{n-k}(U_i)$. The duality maps are compatible, so $D_M = \operatorname{colim}_i D_{U_i}$ is an isomorphism.

(C) $M = U \subseteq \mathbb{R}^n$ convex open. If $K \subseteq U$ is compact, cover it by finitely many closed balls $D_1, \dots, D_m \subseteq U$; their convex hull is the image of the compact set $\Delta^{m-1} \times D_1 \times \cdots \times D_m$ under $(t, x) \mapsto \sum_j t_j x_j$, hence a compact convex subset of U containing K. So compact convex sets C are cofinal, and for $x \in C$ the restriction $H^k(U \mid C) \to H^k(U \mid x)$ is an isomorphism (excise to $\mathbb{R}^n$ and argue as in Step 2 of the proof of Lemma 23.4.2). Hence $H_c^k(U)$ is 0 for $k \neq n$, and so is $H_{n-k}(U)$, as U is contractible. For $k = n$, $H^n(U \mid C) \cong \operatorname{Hom}(H_n(U \mid C;\mathbb{Z}), R)$ by universal coefficients, and the composite of D_U with the augmentation $H_0(U) \cong R$ sends φ to $\varphi(\mu_C)$ by Proposition 22.7.2(3) (with $\psi = 1$). Since μ_C is a unit times the image of a generator of $H_n(U \mid C;\mathbb{Z}) \cong \mathbb{Z}$, this is an isomorphism.

(D) $M = U \subseteq \mathbb{R}^n$ open. Finite unions of convex open sets satisfy duality by (C) and (A), by induction on the number of sets, since $(U_1 \cup \cdots \cup U_{m-1}) \cap U_m$ is a union of $m - 1$ convex open sets. The open set U is the union of countably many open balls $B_1, B_2, \dots$ (Proposition 18.3.12), hence the increasing union of the sets $B_1 \cup \cdots \cup B_m$; apply (B).

(E) General M. By Zorn's lemma and (B), there is an open $U \subseteq M$ maximal among open sets for which duality holds. If $U \neq M$, choose a chart $V \cong \mathbb{R}^n$ not contained in U. Duality

holds for V and for $U \cap V$, which is an open subset of $\mathbb{R}^n$, by (D); so it holds for $U \cup V$ by (A), contradicting maximality. □

Corollary 23.6.3. *Let M be a closed F-oriented n-manifold over a field F. The pairing $H^k(M;F) \times H^{n-k}(M;F) \to F$, $(\alpha,\beta) \mapsto \langle \alpha \smile \beta, [M]\rangle$, is nondegenerate: $\alpha \mapsto \langle \alpha \smile -, [M]\rangle$ is injective, and it is an isomorphism $H^k(M;F) \cong \mathrm{Hom}_F(H^{n-k}(M;F),F)$ when these spaces are finite-dimensional (which is always the case [Hat02, Appendix]).*

Proof. By Proposition 22.7.2(3), $\langle \alpha \smile \beta, [M]\rangle = \langle \beta, [M] \frown \alpha\rangle$. By the universal coefficient theorem over a field, $H^{n-k}(M;F) = \mathrm{Hom}_F(H_{n-k}(M;F),F)$, so $\langle \alpha \smile -, [M]\rangle$ is the functional "evaluate on $[M] \frown \alpha$" on this dual space. Since $\alpha \mapsto [M] \frown \alpha$ is injective, and a nonzero vector is detected by the dual space, the map is injective; for finite dimensions it is bijective by counting dimensions. □

Corollary 23.6.4. *Let M be a closed n-manifold whose integral homology is finitely generated, and define $\chi(M) = \sum_i (-1)^i \operatorname{rank} H_i(M;\mathbb{Z})$. Then $\chi(M) = \sum_i (-1)^i \dim_F H_i(M;F)$ for every field F, and $\chi(M) = 0$ if n is odd.*

Proof. By the universal coefficient theorem (Theorem 21.8.2), $\dim_F H_i(M;F) = \operatorname{rank} H_i(M) + t_i + t_{i-1}$, where t_i is the number of cyclic summands of $H_i(M)$ of order divisible by the characteristic of F (these contribute to $H_i \otimes F$ and to $\mathrm{Tor}_1(H_i,F)$). The t terms cancel in the alternating sum. Take $F = \mathbb{F}_2$, for which M is oriented (Proposition 23.3.2). By duality and universal coefficients, $\dim H_i(M;\mathbb{F}_2) = \dim H^{n-i}(M;\mathbb{F}_2) = \dim H_{n-i}(M;\mathbb{F}_2)$, so $\chi(M) = (-1)^n \chi(M)$. □

Definition 23.6.5. Let M be a closed oriented manifold of dimension $4m$. The *intersection form* is the symmetric bilinear form $Q(\alpha,\beta) = \langle \alpha \smile \beta, [M]\rangle$ on $H^{2m}(M;\mathbb{R})$; it is nondegenerate by Corollary 23.6.3, and symmetric by Theorem 22.3.4. Its *signature* $\sigma(M)$ is the number of positive minus the number of negative eigenvalues. On the free group $H^{2m}(M;\mathbb{Z})/\text{torsion}$ the integral form is unimodular (determinant ± 1) [Hat02, Proposition 3.38]. In dimension $4m+2$ the form on H^{2m+1} is skew-symmetric and nondegenerate.

Example 23.6.6.

1. For $\mathbb{CP}^2$ with the orientation for which $\langle \alpha^2, [\mathbb{CP}^2]\rangle = 1$, $Q = (1)$ and $\sigma = 1$. For $S^2 \times S^2$, in the basis a, b of Example 22.4.3, $Q = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ and $\sigma = 0$. The connected sum $\mathbb{CP}^2 \# \overline{\mathbb{CP}^2}$ (with reversed orientation on the second summand) has the same Betti numbers as $S^2 \times S^2$, but its integral form is $\mathrm{diag}(1,-1)$, which takes odd values, whereas the form of $S^2 \times S^2$ takes only even values on the diagonal; so the forms are not isomorphic over $\mathbb{Z}$ and the two manifolds are not homotopy equivalent (Counterexample 23.6.7).

2. (Cohomology of $\mathbb{CP}^n$ via duality.) The inclusion $\mathbb{CP}^{n-1} \to \mathbb{CP}^n$ is an isomorphism on H^i for $i \le 2n-2$ by cellular cohomology. By induction on n, α^{n-1} generates $H^{2n-2}(\mathbb{CP}^n)$. Since $\mathbb{CP}^n$ is a closed simply connected manifold (Example 19.7.3), it is orientable, and by unimodularity of the pairing $H^2 \times H^{2n-2} \to H^{2n} \cong \mathbb{Z}$ between free groups of rank 1, $\alpha \smile \alpha^{n-1}$ generates H^{2n}. This proves the part of Theorem 22.5.1 about $\mathbb{CP}^n$; the argument for $\mathbb{RP}^n$ with $\mathbb{F}_2$-coefficients is the same.

Counterexample 23.6.7. Homology groups do not determine a closed simply connected 4-manifold up to homotopy equivalence; the cup product is needed. The manifolds S^4, $\mathbb{CP}^2$ and $S^2 \times S^2$ are closed and simply connected (Corollary 19.5.2, Example 19.7.3 and Proposition 19.3.5), but they are told apart already by H_2, which is 0, $\mathbb{Z}$ and $\mathbb{Z}^2$. The interesting pair is $M = S^2 \times S^2$ and $N = \mathbb{CP}^2 \# \overline{\mathbb{CP}^2}$ of Example 23.6.6(1).

1. *N is simply connected.* If X is a closed simply connected n-manifold with $n \geq 3$ and X' is X minus an open coordinate ball, then X is obtained from X' by attaching an n-cell, so $\pi_1(X') \cong \pi_1(X) = 1$ (Proposition 19.5.5). The connected sum is the union of two such pieces along a sphere S^3; thickening them slightly, they become open sets that deformation retract onto the pieces and meet in $S^3 \times (-1, 1)$, which is simply connected, so $\pi_1(N) = 1$ by Corollary 19.5.2.

2. *Same homology.* Both have homology $\mathbb{Z}, 0, \mathbb{Z}^2, 0, \mathbb{Z}$ in degrees $0, \dots, 4$. For N: collapsing the gluing sphere S^3 gives a map $N \to N/S^3 = \mathbb{CP}^2 \vee \overline{\mathbb{CP}^2}$ which, by the long exact sequence of the pair (N, S^3) and $\tilde{H}^k(S^3) = 0$ for $k \leq 2$, is an isomorphism on H^k for $k \leq 2$; on H^4 it sends the generator of each summand (the class pairing to 1 with its fundamental class) to the generator of $H^4(N; \mathbb{Z})$, since the collapse map has degree one on each summand. In the wedge the product of classes from different summands vanishes (Example 22.3.5). This gives the form $\mathrm{diag}(1, -1)$ on $H^2(N; \mathbb{Z}) \cong \mathbb{Z}^2$.

3. *Not homotopy equivalent.* A homotopy equivalence $f : N \to M$ induces an isomorphism of cohomology rings, which is ± 1 on $H^4 \cong \mathbb{Z}$; so f^* would identify the integral intersection form of M with $\pm$ that of N. But $Q_M(x, x) = 2pq$ is even for every $x = pa + qb \in H^2(M; \mathbb{Z})$, while $Q_N(e, e) = \pm 1$ for the generator e coming from $\mathbb{CP}^2$.

The same argument separates $S^2 \times S^2$ from $\mathbb{CP}^2 \# \mathbb{CP}^2$, whose form $\mathrm{diag}(1, 1)$ is moreover definite.

Remark 23.6.8. Compare the case where the homology is that of a sphere. Let M be a closed simply connected 4-manifold with $H_*(M) \cong H_*(S^4)$. Then $\pi_2(M) = \pi_3(M) = 0$ and $\pi_4(M) \cong H_4(M) \cong \mathbb{Z}$ by the Hurewicz theorem, and a map $S^4 \to M$ representing a generator induces isomorphisms on all homology groups; as M has the homotopy type of a CW complex, it is a homotopy equivalence by Whitehead's theorem in its homological form [Hat02, Section 4.2 and Appendix]. So a simply connected homology 4-sphere is a homotopy 4-sphere, and Freedman proved that it is homeomorphic to S^4, the topological Poincaré conjecture in dimension 4 [Fre82]; whether it must be *diffeomorphic* to S^4 is the smooth Poincaré conjecture in dimension 4, which is open. Counterexample 23.6.7 shows that as soon as $H_2 \neq 0$ homology is not enough. What is enough is the cup product: by theorems of Whitehead and Milnor, the homotopy type of a closed simply connected 4-manifold is determined by its integral intersection form [Whi49], [Mil58], and by Freedman its homeomorphism type is determined by the form together with one invariant in $\mathbb{Z}/2\mathbb{Z}$.

23.7 Other dualities

Theorem 23.7.1 (Lefschetz duality)**.** *Let M be a compact R-orientable n-manifold with boundary. There is a fundamental class $[M] \in H_n(M, \partial M; R)$ restricting to local orientations, and cap product with it gives isomorphisms $H^k(M, \partial M; R) \cong H_{n-k}(M; R)$ and $H^k(M; R) \cong H_{n-k}(M, \partial M; R)$.*

This is [Hat02, Theorem 3.43]; the proof uses a collar neighbourhood of ∂M to reduce to Theorem 23.6.2 for the interior of M.

Theorem 23.7.2 (Alexander duality)**.** *Let $K \subsetneq S^n$ be a compact, locally contractible, nonempty subspace. Then $\tilde{H}_i(S^n \setminus K; \mathbb{Z}) \cong \tilde{H}^{n-i-1}(K; \mathbb{Z})$ for all i.*

This is [Hat02, Theorem 3.44]. The idea: $\tilde{H}_i(S^n \setminus K) \cong H_c^{n-i}(S^n \setminus K)$ by duality, and $H_c^{n-i}(S^n \setminus K)$ is the colimit of $H^{n-i}(S^n, U)$ over open neighbourhoods U of K, which for locally contractible K is $H^{n-i}(S^n, K) \cong \tilde{H}^{n-i-1}(K)$.

Corollary 23.7.3 (Jordan–Brouwer separation theorem)**.** *If $K \subseteq S^n$ is homeomorphic to S^{n-1}, then $S^n \setminus K$ has exactly two path components. If K is homeomorphic to D^k, then $S^n \setminus K$ is path-connected.*

Proof. By Theorem 23.7.2, $\tilde{H}_0(S^n \setminus K) \cong \tilde{H}^{n-1}(S^{n-1}) \cong \mathbb{Z}$, respectively $\tilde{H}^{n-1}(D^k) = 0$. Since $S^n \setminus K$ is an open subset of a manifold, its path components are its components, and $\tilde{H}_0$ is free of rank one less than their number (Proposition 21.2.5). □

23.8 Borel–Moore homology and fundamental classes

Remark 23.8.1. For a locally compact space X, *Borel–Moore homology* $H_i^{BM}(X; R)$ is the homology of locally finite, possibly infinite, singular chains; for reasonable X (for instance a closed subspace of a manifold that is locally contractible, or a CW pair) it can be computed as $H_i(X^+, \{\infty\}; R)$, where X^+ is the one-point compactification. It is covariant for proper maps, contravariant for open inclusions, and a manifold M oriented over R has a fundamental class $[M] \in H_n^{BM}(M; R)$ even when it is not compact, with $H^k(M; R) \cong H_{n-k}^{BM}(M; R)$. If Z is a closed subset of an R-oriented n-manifold M, then

$$H_i^{BM}(Z; R) \cong H^{n-i}(M, M \setminus Z; R),$$

which for $Z = M$ is the duality above. See [Bre97, Chapter V], [Ive86] and [Ful98, Chapter 19].

Remark 23.8.2. These isomorphisms produce cohomology classes from subspaces. If $N \subseteq M$ is a closed oriented submanifold of dimension d (or, more generally, a closed subspace of "dimension" d with a fundamental class $[N] \in H_d^{BM}(N; R)$), its image under $H_d^{BM}(N) \cong H^{n-d}(M, M \setminus N) \to H^{n-d}(M)$ is the *cohomology class of* N. When N and M are compact it is the Poincaré dual of $i_*[N] \in H_d(M)$. A complex subvariety Z of complex dimension d of a complex manifold of dimension m has a fundamental class in $H_{2d}^{BM}(Z; \mathbb{Z})$ because its singular locus has real codimension at least 2; this gives the *cycle class* $[Z] \in H^{2m-2d}(X; \mathbb{Z})$ of Chapter 63, and the Hodge conjecture asks which rational classes are combinations of such $[Z]$. Under these identifications, cup product corresponds to intersection of cycles meeting transversally.

23.9 Exercises

Exercise 23.9.1. Let M be a closed connected n-manifold with finitely generated homology. Show that the torsion subgroup of $H_{n-1}(M; \mathbb{Z})$ is 0 if M is orientable and $\mathbb{Z}/2\mathbb{Z}$ otherwise.

Solution. By universal coefficients, $H_n(M; \mathbb{Z}/m) \cong H_n(M) \otimes \mathbb{Z}/m \oplus \operatorname{Tor}_1(H_{n-1}(M), \mathbb{Z}/m)$, and $\operatorname{Tor}_1(\mathbb{Z}/a, \mathbb{Z}/m) \cong \mathbb{Z}/\gcd(a, m)$. If M is orientable, $H_n(M) = \mathbb{Z}$ and $H_n(M; \mathbb{Z}/m) \cong \mathbb{Z}/m$ (Theorem 23.4.3), so all $\operatorname{Tor}_1(H_{n-1}, \mathbb{Z}/m)$ vanish and H_{n-1} is torsion-free. Otherwise $H_n(M) = 0$ and $H_n(M; \mathbb{Z}/m) \cong \{r : 2r = 0\}$: for m an odd prime this is 0, so there is no odd torsion; for $m = 2$ it is $\mathbb{Z}/2$, so there is exactly one cyclic summand of even order; for $m = 4$ it is $\mathbb{Z}/2$, which forces that summand to be $\mathbb{Z}/2$. □

Exercise 23.9.2. Show that $\mathbb{RP}^n$ is orientable if and only if n is odd.

Solution. By Example 21.7.5, $H_n(\mathbb{RP}^n; \mathbb{Z})$ is $\mathbb{Z}$ for n odd and 0 for n even; apply Theorem 23.4.3. □

Exercise 23.9.3. Show that a closed simply connected 3-manifold has the homology of S^3.

Solution. It is orientable (Proposition 23.3.2), so $H_3 \cong \mathbb{Z}$ and $H_i = 0$ for $i > 3$. $H_1 = \pi_1^{\text{ab}} = 0$. By duality $H_2 \cong H^1 \cong \text{Hom}(H_1, \mathbb{Z}) \oplus \text{Ext}^1(H_0, \mathbb{Z}) = 0$. □

Exercise 23.9.4. Show that $\sigma(M) = 0$ if M admits an orientation-reversing self-homeomorphism, and compute the intersection form of T^4.

Exercise 23.9.5. Let $K \subseteq S^3$ be homeomorphic to S^1. Show that $H_1(S^3 \setminus K; \mathbb{Z}) \cong \mathbb{Z}$ and $H_2(S^3 \setminus K; \mathbb{Z}) = 0$.

Chapter 24

Cohomology Operations

24.1 Introduction

A cohomology operation is a natural transformation between cohomology functors, such as $x \mapsto x^2$. Because cohomology is represented by Eilenberg–MacLane spaces, operations are the same as cohomology classes of these spaces (Proposition 24.3.2). The Steenrod squares are the most important operations with $\mathbb{F}_2$-coefficients; they refine the cup product and give obstructions that cup products cannot see, such as the theorem that a map of Hopf invariant one $S^{2n-1} \to S^n$ exists only if n is a power of 2 (Corollary 24.4.4). For the Hodge conjecture, operations show that some integral cohomology classes of smooth projective varieties cannot be classes of algebraic cycles (Remark 24.6.2). This chapter is partly a survey: the existence theorems are quoted from [Hat02], [SE62] and [MT68], and what follows from them is proved.

Prerequisites. Chapter 23 (Topological Manifolds and Poincaré Duality) and Chapter 19 (Homotopy and Covering Spaces).

On the way to the Hodge conjecture. This chapter is not needed. Later chapters use it only for the Stiefel–Whitney classes and Wu's formula in Chapter 39; it can be skipped until then.

24.2 Eilenberg–MacLane spaces

Definition 24.2.1. Let G be a group and $n \geq 1$, with G abelian if $n \geq 2$. An *Eilenberg–MacLane space* $K(G, n)$ is a connected CW complex with $\pi_n(K(G,n)) \cong G$ and $\pi_i(K(G,n)) = 0$ for $i \neq n$.

Theorem 24.2.2. *For every $n \geq 1$ and every group G (abelian if $n \geq 2$) there is an Eilenberg–MacLane space $K(G, n)$, which can be chosen with a single 0-cell and no other cells of dimension less than n; any two are homotopy equivalent.*

For the proof, which attaches cells to a wedge of n-spheres to realise a presentation of G and then kills the higher homotopy groups, see [Hat02, Section 4.2].

Example 24.2.3.

1. S^1 is a $K(\mathbb{Z}, 1)$, since its universal covering $\mathbb{R}$ is contractible and $\pi_i(S^1) \cong \pi_i(\mathbb{R}) = 0$ for $i \geq 2$ (Proposition 19.8.3). More generally, a connected CW complex with contractible universal covering is a $K(\pi_1, 1)$; this applies to the tori T^n and to the surfaces Σ_g with $g \geq 1$.

2. $\mathbb{RP}^\infty = \bigcup_n \mathbb{RP}^n$ is a $K(\mathbb{Z}/2\mathbb{Z}, 1)$ and $\mathbb{CP}^\infty$ is a $K(\mathbb{Z}, 2)$: they are the quotients of the contractible space $S^\infty = \bigcup_n S^n$ by $\{\pm 1\}$ and by the circle group, and the long exact sequence of the fibration $S^1 \to S^\infty \to \mathbb{CP}^\infty$ gives $\pi_2(\mathbb{CP}^\infty) \cong \pi_1(S^1)$ [Hat02, Section 4.2].

Theorem 24.2.4 (Representability)**.** *Let G be abelian and $n \geq 1$. There is a class $\iota_n \in H^n(K(G,n);G)$ such that for every CW complex X the map $\langle X, K(G,n)\rangle \to H^n(X;G)$, $[f] \mapsto f^*(\iota_n)$, is a bijection, natural in X.*

This is [Hat02, Theorem 4.57]. The class ι_n corresponds under $H^n(K(G,n);G) \cong \mathrm{Hom}(H_n(K(G,n)),G) \cong \mathrm{Hom}(\pi_n(K(G,n)),G) = \mathrm{Hom}(G,G)$ (universal coefficients and the Hurewicz theorem) to the identity.

24.3 Cohomology operations

Definition 24.3.1. A *cohomology operation* of type $(G,m;H,n)$ is a family of maps of sets $\theta_X\colon H^m(X;G) \to H^n(X;H)$, one for each space X, such that $f^*\theta_Y = \theta_X f^*$ for every map $f\colon X \to Y$. It is *additive* if every θ_X is a homomorphism.

Proposition 24.3.2. *Restricted to pointed CW complexes, operations of type $(G,m;H,n)$ correspond bijectively to elements of $H^n(K(G,m);H)$, via $\theta \mapsto \theta(\iota_m)$.*

Proof. On the category whose objects are pointed CW complexes and whose morphisms are pointed homotopy classes of maps, $H^m(-;G)$ is represented by $(K(G,m),\iota_m)$, by Theorem 24.2.4 and Definition 6.6.6, and $H^n(-;H)$ is a functor to Set by homotopy invariance. Operations are natural transformations between them, and the Yoneda lemma (Theorem 6.6.1) identifies these with $H^n(K(G,m);H)$. Explicitly, $u \in H^n(K(G,m);H)$ gives $\theta(x) = f_x^*(u)$, where $f_x\colon X \to K(G,m)$ is the map with $f_x^*(\iota_m) = x$. □

Example 24.3.3.

1. For a commutative ring R, $x \mapsto x^k$ is an operation of type $(R,m;R,km)$, corresponding to ι_m^k; it is not additive in general.
2. A homomorphism $G \to H$ induces an additive operation of type $(G,m;H,m)$, for example the reduction $\rho\colon H^m(X;\mathbb{Z}) \to H^m(X;\mathbb{Z}/p\mathbb{Z})$.
3. Since $H^n(K(G,m);H) = 0$ for $0 < n < m$ ($K(G,m)$ may be chosen with no cells in dimensions $0 < i < m$), there are no nonzero operations lowering degree, except constant ones for $n = 0$.

Proposition 24.3.4 (Bockstein homomorphisms)**.** *Let p be a prime. The short exact sequences $0 \to \mathbb{Z} \xrightarrow{p} \mathbb{Z} \to \mathbb{Z}/p \to 0$ and $0 \to \mathbb{Z}/p \to \mathbb{Z}/p^2 \to \mathbb{Z}/p \to 0$ induce connecting homomorphisms $\tilde\beta\colon H^n(X;\mathbb{Z}/p) \to H^{n+1}(X;\mathbb{Z})$ and $\beta\colon H^n(X;\mathbb{Z}/p) \to H^{n+1}(X;\mathbb{Z}/p)$, the* Bockstein *operations. They satisfy $\beta = \rho\tilde\beta$, $\beta\beta = 0$, the image of $\tilde\beta$ is the p-torsion subgroup $\{y : py = 0\}$ of $H^{n+1}(X;\mathbb{Z})$, and the kernel of $\tilde\beta$ is the image of the reduction $\rho\colon H^n(X;\mathbb{Z}) \to H^n(X;\mathbb{Z}/p)$.*

Proof. Since each $C_n(X)$ is free, $\mathrm{Hom}(C_n(X),-)$ is exact, so a short exact sequence of coefficient groups gives a short exact sequence of cochain complexes and a long exact sequence (Theorem 15.4.3): $H^n(X;\mathbb{Z}) \xrightarrow{p} H^n(X;\mathbb{Z}) \xrightarrow{\rho} H^n(X;\mathbb{Z}/p) \xrightarrow{\tilde\beta} H^{n+1}(X;\mathbb{Z}) \xrightarrow{p} H^{n+1}(X;\mathbb{Z})$. Exactness gives the descriptions of the image and the kernel of $\tilde\beta$. The reduction $\mathbb{Z} \to \mathbb{Z}/p^2$ gives a morphism from the first short exact sequence to the second, and naturality of connecting homomorphisms gives $\beta = \rho\tilde\beta$. Finally $\beta\beta = \rho\tilde\beta\rho\tilde\beta = 0$ because $\tilde\beta\rho = 0$. □

24.4 Steenrod squares

Theorem 24.4.1 (Steenrod)**.** *There are unique additive operations $\mathrm{Sq}^i\colon H^n(X;\mathbb{F}_2) \to H^{n+i}(X;\mathbb{F}_2)$, $i \geq 0$, defined for all spaces and pairs and natural, such that:*

1. $\mathrm{Sq}^0 = \mathrm{id}$;
2. $\mathrm{Sq}^n(x) = x^2$ *if* $|x| = n$, *and* $\mathrm{Sq}^i(x) = 0$ *if* $i > |x|$;
3. *(Cartan formula)* $\mathrm{Sq}^i(xy) = \sum_{j+k=i} \mathrm{Sq}^j(x)\mathrm{Sq}^k(y)$;
4. *they commute with the suspension isomorphisms* $\tilde{H}^n(X) \cong \tilde{H}^{n+1}(SX)$ *and with the connecting homomorphisms of pairs.*

Moreover Sq^1 *is the Bockstein* β *for* $p = 2$, *and for* $a < 2b$ *the* Adem relations

$$\mathrm{Sq}^a\mathrm{Sq}^b = \sum_{c=0}^{\lfloor a/2 \rfloor} \binom{b-c-1}{a-2c} \mathrm{Sq}^{a+b-c}\mathrm{Sq}^c$$

hold, with binomial coefficients taken modulo 2.

See [SE62] and [Hat02, Section 4.L]. Writing $\mathrm{Sq} = \sum_i \mathrm{Sq}^i$ (a finite sum on each class), the Cartan formula says that $\mathrm{Sq}\colon H^*(X;\mathbb{F}_2) \to H^*(X;\mathbb{F}_2)$ is a ring homomorphism. There are analogous *reduced power operations* $P^i\colon H^n(X;\mathbb{F}_p) \to H^{n+2i(p-1)}(X;\mathbb{F}_p)$ for odd primes p, with $P^i(x) = x^p$ for $|x| = 2i$.

Proposition 24.4.2. *In* $H^*(\mathbb{RP}^\infty;\mathbb{F}_2) = \mathbb{F}_2[\alpha]$, $\mathrm{Sq}^i(\alpha^n) = \binom{n}{i}\alpha^{n+i}$. *In* $H^*(\mathbb{CP}^\infty;\mathbb{F}_2) = \mathbb{F}_2[x]$ *with* $|x| = 2$, $\mathrm{Sq}^{2i}(x^n) = \binom{n}{i}x^{n+i}$ *and* $\mathrm{Sq}^{2i+1} = 0$.

Proof. By axioms (1) and (2), $\mathrm{Sq}(\alpha) = \alpha + \alpha^2$. Since Sq is a ring homomorphism, $\mathrm{Sq}(\alpha^n) = (\alpha+\alpha^2)^n = \alpha^n(1+\alpha)^n = \sum_i \binom{n}{i}\alpha^{n+i}$; compare degrees. For $\mathbb{CP}^\infty$, $\mathrm{Sq}^1(x) \in H^3 = 0$, so $\mathrm{Sq}(x) = x + x^2$ and the same computation applies, all odd squares vanishing for degree reasons. The rings are those of Theorem 22.5.1. □

Lemma 24.4.3. *If* $i \geq 1$ *is not a power of* 2, *then* Sq^i *is* decomposable*: it is a sum of composites* $\mathrm{Sq}^a\mathrm{Sq}^b$ *with* $0 < a, b < i$.

Proof. Choose k with $2^k < i < 2^{k+1}$ and let $a = i - 2^k$, so $0 < a < 2^k$ and $a < 2 \cdot 2^k$. In $\mathbb{F}_2[t]$ we have $(1+t)^{2^k} = 1 + t^{2^k}$ (the Frobenius map is a ring homomorphism), hence $(1+t)^{2^k-1} = (1+t^{2^k})/(1+t) = 1 + t + \cdots + t^{2^k-1}$, so $\binom{2^k-1}{a}$ is odd. The Adem relation for $\mathrm{Sq}^a\mathrm{Sq}^{2^k}$ has $c = 0$ term $\binom{2^k-1}{a}\mathrm{Sq}^i = \mathrm{Sq}^i$, so $\mathrm{Sq}^i = \mathrm{Sq}^a\mathrm{Sq}^{2^k} + \sum_{c\geq 1}\binom{2^k-c-1}{a-2c}\mathrm{Sq}^{i-c}\mathrm{Sq}^c$, and all indices lie strictly between 0 and i. □

Corollary 24.4.4 (Hopf invariant one)**.** *Let* $n \geq 2$ *and* $f\colon S^{2n-1} \to S^n$, *and let* $X_f = S^n \cup_f D^{2n}$, *with* $H^n(X_f;\mathbb{Z}) = \mathbb{Z}a$ *and* $H^{2n}(X_f;\mathbb{Z}) = \mathbb{Z}b$. *Define the* Hopf invariant $h(f)$ *by* $a^2 = h(f)b$. *If* $h(f)$ *is odd, then* n *is a power of* 2.

Proof. X_f has cells in dimensions $0, n, 2n$, so by cellular cohomology its integral cohomology is free of rank one in these degrees and zero elsewhere, and the reductions $\bar{a}, \bar{b}$ generate the $\mathbb{F}_2$-cohomology. Reduction is a ring homomorphism, so $\mathrm{Sq}^n(\bar{a}) = \bar{a}^2 = h(f)\bar{b} \neq 0$. If n were not a power of 2, Lemma 24.4.3 would write $\mathrm{Sq}^n(\bar{a})$ as a sum of terms $\mathrm{Sq}^a\mathrm{Sq}^b(\bar{a})$ with $0 < b < n$, and $\mathrm{Sq}^b(\bar{a}) \in H^{n+b}(X_f;\mathbb{F}_2) = 0$. □

Remark 24.4.5. The Hopf maps $S^3 \to S^2$, $S^7 \to S^4$ and $S^{15} \to S^8$ have Hopf invariant one. Adams proved, using secondary cohomology operations, that maps of Hopf invariant one exist only for $n = 1, 2, 4, 8$ [Ada60]. Consequences include the facts that $\mathbb{R}^n$ admits a bilinear multiplication without zero divisors only for $n = 1, 2, 4, 8$, and that S^{n-1} is an H-space only for $n = 1, 2, 4, 8$.

24.5 Cohomology of Eilenberg–MacLane spaces

Definition 24.5.1. A sequence $I = (i_1, \dots, i_r)$ of positive integers is *admissible* if $i_j \geq 2i_{j+1}$ for all j. Its *degree* is $\sum_j i_j$, its *excess* is $e(I) = \sum_j (i_j - 2i_{j+1}) = i_1 - i_2 - \cdots - i_r$ (with $i_{r+1} = 0$), and $\mathrm{Sq}^I = \mathrm{Sq}^{i_1} \cdots \mathrm{Sq}^{i_r}$. The empty sequence is admissible with excess 0.

Theorem 24.5.2 (Serre)**.** *1. The* Steenrod algebra $\mathcal{A}_2$*, the algebra of operations $H^*(-;\mathbb{F}_2) \to H^*(-;\mathbb{F}_2)$ generated by the Sq^i modulo the Adem relations, has the admissible monomials Sq^I as an $\mathbb{F}_2$-basis.*

2. $H^*(K(\mathbb{Z}/2, n);\mathbb{F}_2)$ is the polynomial algebra on the classes $\mathrm{Sq}^I \iota_n$ with I admissible and $e(I) < n$.

3. $H^*(K(\mathbb{Z}, n);\mathbb{F}_2)$ is the polynomial algebra on the classes $\mathrm{Sq}^I \iota_n$ with I admissible, $e(I) < n$ and $i_r \neq 1$.

This is [Ser53]; see also [MT68].

Example 24.5.3. For $n = 3$, the admissible sequences of excess less than 3 not ending in 1 are $\emptyset$, (2), $(4,2)$, $(8,4,2)$, ... So $H^*(K(\mathbb{Z},3);\mathbb{F}_2) = \mathbb{F}_2[\iota_3, \mathrm{Sq}^2\iota_3, \mathrm{Sq}^4\mathrm{Sq}^2\iota_3, \dots]$ with generators in degrees $3, 5, 9, 17, \dots$. In low degrees: $H^3 = \langle \iota_3 \rangle$, $H^4 = 0$, $H^5 = \langle \mathrm{Sq}^2\iota_3 \rangle$, $H^6 = \langle \iota_3^2 \rangle$, where $\iota_3^2 = \mathrm{Sq}^3\iota_3 = \mathrm{Sq}^1\mathrm{Sq}^2\iota_3$ by the Adem relation $\mathrm{Sq}^1\mathrm{Sq}^2 = \mathrm{Sq}^3$. Since $\mathrm{Sq}^1 = \rho\tilde{\beta}$ is nonzero on $\mathrm{Sq}^2\iota_3$, the integral class $\tilde{\beta}\mathrm{Sq}^2\iota_3 \in H^6(K(\mathbb{Z},3);\mathbb{Z})$ is a nonzero 2-torsion class. In general $x \mapsto \tilde{\beta}\mathrm{Sq}^2\rho(x)$ is an integral operation raising degree by 3, defined in every degree, whose reduction modulo 2 is $\rho\tilde{\beta}\mathrm{Sq}^2\rho(x) = \mathrm{Sq}^1\mathrm{Sq}^2\rho(x) = \mathrm{Sq}^3\rho(x)$; it appears in Remark 24.6.2.

24.6 Complex cobordism and algebraic cycles

Remark 24.6.1. *Complex cobordism MU^** is a generalised cohomology theory: it satisfies all Eilenberg–Steenrod axioms except the dimension axiom. Its coefficient ring is $MU^* = MU^*(\mathrm{pt}) \cong \mathbb{Z}[x_1, x_2, \dots]$ with x_i in degree $-2i$, generated geometrically by classes of complex projective spaces and hypersurfaces [Sto68], and Quillen showed that it carries the universal one-dimensional commutative formal group law [Qui69]. For a compact complex manifold X there is a natural map $MU^*(X) \to H^*(X;\mathbb{Z})$, and a closed complex submanifold $Z \subseteq X$ of codimension c defines a class in $MU^{2c}(X)$ whose image is the cohomology class of Z (Chapter 23). See [Rav86] for the homotopy-theoretic side and [Tho54] for the origins of cobordism.

Remark 24.6.2. Atiyah and Hirzebruch showed that on a smooth projective complex variety X the integral cohomology class of every algebraic cycle lies in the image of $MU^*(X) \to H^*(X;\mathbb{Z})$, using resolution of singularities, and that cohomology operations of odd degree vanish on this image; in particular $\mathrm{Sq}^3\rho(x) = 0$ for the class x of a codimension-2 cycle. They constructed smooth projective varieties with torsion classes $x \in H^4(X;\mathbb{Z})$ with $\mathrm{Sq}^3\rho(x) \neq 0$. Such a class is a Hodge class (torsion classes are Hodge classes trivially), but it is not the class of an algebraic cycle, which disproves the Hodge conjecture with integral coefficients [AH62]. Totaro refined this by showing that the cycle class map factors as $CH^*(X) \to MU^*(X) \otimes_{MU^*} \mathbb{Z} \to H^*(X;\mathbb{Z})$ [Tot97]. These results are developed in Chapter 73.

24.7 Exercises

Exercise 24.7.1. Deduce from the Adem relations that $\mathrm{Sq}^1\mathrm{Sq}^1 = 0$, $\mathrm{Sq}^1\mathrm{Sq}^2 = \mathrm{Sq}^3$ and $\mathrm{Sq}^2\mathrm{Sq}^2 = \mathrm{Sq}^3\mathrm{Sq}^1$.

Solution. For $(a,b) = (1,1)$ the only term is $c = 0$ with coefficient $\binom{0}{1} = 0$. For $(1,2)$: $\binom{1}{1}\mathrm{Sq}^3\mathrm{Sq}^0 = \mathrm{Sq}^3$. For $(2,2)$: $c = 0$ gives $\binom{1}{2} = 0$ and $c = 1$ gives $\binom{0}{0}\mathrm{Sq}^3\mathrm{Sq}^1$. □

Exercise 24.7.2. Show that there is no space X with $H^*(X;\mathbb{F}_2) \cong \mathbb{F}_2[x]$ and $|x| = 3$.

Solution. We would have $x^2 = \mathrm{Sq}^3 x = \mathrm{Sq}^1\mathrm{Sq}^2 x$, and $\mathrm{Sq}^2 x \in H^5(X;\mathbb{F}_2) = 0$, so $x^2 = 0$, contradicting that H^* is a polynomial ring. (More generally, the argument of Corollary 24.4.4 shows that $|x|$ must be a power of 2, and by Adams' theorem (Remark 24.4.5) only $|x| = 1, 2, 4, 8$ can occur.) □

Exercise 24.7.3. Show that $\beta(\alpha^n) = n\alpha^{n+1}$ in $H^*(\mathbb{RP}^\infty;\mathbb{F}_2)$, directly from the cellular cochain complex, and compare with Proposition 24.4.2.

Exercise 24.7.4. Show that the attaching map $S^3 \to S^2$ of the 4-cell of $\mathbb{CP}^2$ is not null-homotopic, using Sq^2 or the cup product, and deduce that $\pi_3(S^2) \neq 0$.

Solution. If it were null-homotopic, $\mathbb{CP}^2$ would be homotopy equivalent to $S^2 \vee S^4$ (attaching along homotopic maps gives homotopy equivalent spaces [Hat02, Proposition 0.18]), whose cup squares in degree 2 vanish; but $\mathrm{Sq}^2(x) = x^2 \neq 0$ in $H^4(\mathbb{CP}^2;\mathbb{F}_2)$ by Theorem 22.5.1. □

Part IV

Sheaves

Chapter 25

Sheaves on Topological Spaces

25.1 Introduction

A sheaf on a space records data that are defined locally and glue uniquely: continuous, smooth or holomorphic functions, sections of a bundle, solutions of a differential equation. Sheaves are the language in which complex and algebraic geometry and Hodge theory are written: the cohomology of sheaves (Chapter 26) unifies singular, de Rham and Dolbeault cohomology, and the comparison between them is the starting point of Hodge theory. This chapter develops the basic theory: sheaves and stalks, sheafification, the abelian category of sheaves, direct and inverse images, local systems, and sheaves of modules. References are [God58], [Bre97], [KS90], [Har77, Chapter II] and [The].

Prerequisites. Chapter 18 (General Topology), Chapter 6 (Categories), Chapter 15 (Homological Algebra) and Chapter 19 (Homotopy and Covering Spaces).

On the way to the Hodge conjecture. Needed: presheaves and sheaves, sheafification, direct and inverse images, and ringed spaces. Local systems (Section 25.5) are used for variations of Hodge structure and can be postponed.

Throughout, X is a topological space and $\mathrm{Open}(X)$ is the set of open subsets of X, ordered by inclusion and viewed as a category.

25.2 Presheaves and sheaves

Definition 25.2.1. A *presheaf* $\mathcal{F}$ on X with values in a category $\mathcal{C}$ (sets, abelian groups, rings, modules) is a functor $\mathcal{F} : \mathrm{Open}(X)^{\mathrm{op}} \to \mathcal{C}$: an object $\mathcal{F}(U)$, the *sections* over U, for each open U, and *restriction maps* $\mathcal{F}(U) \to \mathcal{F}(V)$, $s \mapsto s|_V$, for $V \subseteq U$, with $s|_U = s$ and $(s|_V)|_W = s|_W$. We also write $\Gamma(U, \mathcal{F}) = \mathcal{F}(U)$. A *morphism* of presheaves is a natural transformation. A presheaf of sets (or abelian groups, ...) is a *sheaf* if for every open cover $U = \bigcup_i U_i$:

1. (Locality) if $s, t \in \mathcal{F}(U)$ satisfy $s|_{U_i} = t|_{U_i}$ for all i, then $s = t$;
2. (Gluing) if $s_i \in \mathcal{F}(U_i)$ satisfy $s_i|_{U_i \cap U_j} = s_j|_{U_i \cap U_j}$ for all i, j, there is $s \in \mathcal{F}(U)$ with $s|_{U_i} = s_i$ for all i.

Sheaves form full subcategories $\mathrm{Sh}(X) \subseteq \mathrm{PSh}(X)$ and $\mathrm{Ab}(X) \subseteq \mathrm{PAb}(X)$. Applied to the empty cover of $\emptyset$, the axioms say that $\mathcal{F}(\emptyset)$ is a single point (the zero group).

Example 25.2.2. 1. For a space Y, $U \mapsto \{\text{continuous maps } U \to Y\}$ is a sheaf of sets, because continuity is local (pasting lemma, Lemma 18.4.5). For $Y = \mathbb{R}$ or $\mathbb{C}$ it is a sheaf of rings C_X. Likewise smooth functions on a manifold and holomorphic functions on an open subset of $\mathbb{C}$ form sheaves of rings.

2. For a continuous map $p\colon E \to X$, the continuous sections $s\colon U \to E$ with $ps = \mathrm{id}_U$ form a sheaf of sets, the *sheaf of sections* of p.

3. Let A be a set with at least two elements. The *constant presheaf* $U \mapsto A$ (with $\emptyset \mapsto$ a point) is not a sheaf if X has two disjoint nonempty open subsets U_1, U_2: sections $a \neq b$ on them do not glue to a section on $U_1 \sqcup U_2$. The *constant sheaf* A_X is $U \mapsto \{\text{locally constant maps } U \to A\}$.

4. For $x \in X$ and a set (group) A, the *skyscraper sheaf* x_*A has $x_*A(U) = A$ if $x \in U$ and a point otherwise.

5. The presheaf of bounded continuous functions on $\mathbb{R}$ satisfies locality but not gluing.

Definition 25.2.3. The *stalk* of a presheaf $\mathcal{F}$ at x is $\mathcal{F}_x = \operatorname{colim}_{U \ni x} \mathcal{F}(U)$, the colimit over the open neighbourhoods of x directed by reverse inclusion (Example 6.11.2). By Proposition 6.11.4, its elements are *germs* s_x of sections $s \in \mathcal{F}(U)$, $x \in U$, where $s_x = t_x$ for $t \in \mathcal{F}(V)$ if and only if $s|_W = t|_W$ for some open $W \ni x$ in $U \cap V$. For presheaves of abelian groups the stalk is an abelian group (Lemma 23.5.1). A morphism φ induces maps $\varphi_x\colon \mathcal{F}_x \to \mathcal{G}_x$.

Proposition 25.2.4. *Let $\varphi\colon \mathcal{F} \to \mathcal{G}$ be a morphism of sheaves.*

1. *Two sections $s, t \in \mathcal{F}(U)$ with $s_x = t_x$ for all $x \in U$ are equal.*

2. *φ_U is injective for all U if and only if φ_x is injective for all x.*

3. *φ is an isomorphism if and only if φ_x is bijective for all x.*

Proof. (1) Each $x \in U$ has an open neighbourhood $W_x \subseteq U$ with $s|_{W_x} = t|_{W_x}$; apply locality to the cover (W_x). (2) If all φ_x are injective and $\varphi(s) = \varphi(t)$, then $\varphi(s)_x = \varphi(t)_x$ gives $s_x = t_x$ for all x, so $s = t$ by (1). Conversely, if $\varphi_x(s_x) = \varphi_x(t_x)$ with $s, t \in \mathcal{F}(U)$, then $\varphi(s)|_W = \varphi(t)|_W$ for some $W \ni x$, so $s|_W = t|_W$ and $s_x = t_x$. (3) An isomorphism induces bijections on stalks. Conversely, by (2) each φ_U is injective. Let $t \in \mathcal{G}(U)$. For each $x \in U$ choose $s^{(x)} \in \mathcal{F}(W_x)$ with $\varphi(s^{(x)})_x = t_x$; shrinking W_x, $\varphi(s^{(x)}) = t|_{W_x}$. On $W_x \cap W_y$, $\varphi(s^{(x)}) = \varphi(s^{(y)})$, so $s^{(x)} = s^{(y)}$ there by injectivity. By gluing there is s with $s|_{W_x} = s^{(x)}$, and $\varphi(s) = t$ by locality. □

Proposition 25.2.5 (Gluing sheaves)**.** *Let $(U_i)_{i \in I}$ be an open cover of X, let $\mathcal{F}_i$ be a sheaf on U_i, and write $U_{ij} = U_i \cap U_j$, $U_{ijk} = U_i \cap U_j \cap U_k$. Let $\varphi_{ij}\colon \mathcal{F}_j|_{U_{ij}} \to \mathcal{F}_i|_{U_{ij}}$ be isomorphisms with $\varphi_{ii} = \mathrm{id}$ and $\varphi_{ij} \circ \varphi_{jk} = \varphi_{ik}$ on U_{ijk} (the* cocycle condition*). Then there is a sheaf $\mathcal{F}$ on X with isomorphisms $\psi_i\colon \mathcal{F}|_{U_i} \to \mathcal{F}_i$ such that $\psi_i = \varphi_{ij} \circ \psi_j$ on U_{ij}, and $(\mathcal{F}, (\psi_i))$ is unique up to unique isomorphism.*

Proof. For U open let $\mathcal{F}(U)$ be the set of families $(s_i)_i$ with $s_i \in \mathcal{F}_i(U \cap U_i)$ and $s_i = \varphi_{ij}(s_j)$ on $U \cap U_{ij}$ for all i, j, with componentwise restriction. The sheaf axioms hold componentwise, since each $\mathcal{F}_i$ is a sheaf and the compatibility conditions can be checked locally (by locality of the $\mathcal{F}_i$). For $V \subseteq U_i$ define $\psi_i((s_j)_j) = s_i$. Its inverse sends $t \in \mathcal{F}_i(V)$ to the family $s_j = \varphi_{ji}(t|_{V \cap U_j})$; this family is compatible because $\varphi_{jk}(s_k) = \varphi_{jk}\varphi_{ki}(t) = \varphi_{ji}(t) = s_j$, and $s_i = t$ because $\varphi_{ii} = \mathrm{id}$. Conversely a compatible family is determined by its i-th member, as $s_j = \varphi_{ji}(s_i)$; so ψ_i is an isomorphism, and $\psi_i = \varphi_{ij}\psi_j$ is the compatibility condition. If $(\mathcal{G}, (\psi_i'))$ is another solution, the isomorphisms $\psi_i^{-1}\psi_i'\colon \mathcal{G}|_{U_i} \to \mathcal{F}|_{U_i}$ agree on the overlaps, since $\psi_i^{-1}\psi_i' = \psi_j^{-1}\varphi_{ij}^{-1}\varphi_{ij}\psi_j' = \psi_j^{-1}\psi_j'$; morphisms of sheaves that agree on overlaps glue uniquely, by the sheaf axioms of the target applied to the images of sections, so they define the unique isomorphism $\mathcal{G} \to \mathcal{F}$ compatible with the ψ's. □

Example 25.2.6. Vector bundles are the basic instance: on a cover trivialising a bundle, the sheaves of sections $\mathcal{F}_i \cong C^r_{U_i}$ are glued by the transition functions, and the cocycle condition of Proposition 25.2.5 is the cocycle condition for transition functions. Local systems (Section 25.5) are glued in the same way from constant sheaves, with locally constant transition functions.

25.3 Sheafification

Theorem 25.3.1. *Let $\mathcal{F}$ be a presheaf of sets (abelian groups). For U open let $\mathcal{F}^\#(U)$ be the set of functions s assigning to each $x \in U$ a germ $s(x) \in \mathcal{F}_x$ such that every $x \in U$ has an open neighbourhood $W \subseteq U$ and $t \in \mathcal{F}(W)$ with $s(y) = t_y$ for all $y \in W$. With restriction of functions, $\mathcal{F}^\#$ is a sheaf, the* sheafification *of $\mathcal{F}$, and $\theta\colon \mathcal{F} \to \mathcal{F}^\#$, $t \mapsto (y \mapsto t_y)$, has the following properties.*

1. *$\theta_x\colon \mathcal{F}_x \to \mathcal{F}_x^\#$ is bijective for all x.*
2. *Every morphism $\varphi\colon \mathcal{F} \to \mathcal{G}$ to a sheaf factors uniquely as $\varphi = \psi \circ \theta$. So sheafification is left adjoint to the inclusion of sheaves into presheaves.*
3. *If $\mathcal{F}$ is a sheaf, θ is an isomorphism.*

Proof. The conditions defining $\mathcal{F}^\#(U)$ are local, so $\mathcal{F}^\#$ is a sheaf; for abelian groups, the pointwise operations preserve the condition.

(1) Surjectivity: an element of $\mathcal{F}_x^\#$ is the germ of some $s \in \mathcal{F}^\#(U)$, which near x equals $\theta(t)$, so the germ is $\theta_x(t_x)$. Injectivity: if $\theta(t)_x = \theta(t')_x$, then in particular $t_x = \theta(t)(x) = \theta(t')(x) = t'_x$.

(2) Let $s \in \mathcal{F}^\#(U)$, and choose an open cover (W_i) of U and $t_i \in \mathcal{F}(W_i)$ with $s|_{W_i} = \theta(t_i)$. On $W_i \cap W_j$ the germs of t_i and t_j agree, hence so do the germs of $\varphi(t_i)$ and $\varphi(t_j)$, and by Proposition 25.2.4(1) $\varphi(t_i) = \varphi(t_j)$ there. Let $\psi(s)$ be the section of $\mathcal{G}$ obtained by gluing. It does not depend on the choices (two choices agree on a common refinement), and ψ is a morphism with $\psi\theta = \varphi$. Uniqueness: any ψ' with $\psi'\theta = \varphi$ agrees with ψ on each $\theta(t_i)$, hence on s by locality.

(3) By (1) and Proposition 25.2.4(3), applied to the morphism θ of sheaves. □

Proposition 25.3.2. $\mathrm{Ab}(X)$ *is an abelian category. The kernel of $\varphi\colon \mathcal{F} \to \mathcal{G}$ is $U \mapsto \ker \varphi_U$; its cokernel is the sheafification of the presheaf $U \mapsto \operatorname{coker} \varphi_U$. Taking stalks is exact:* $(\ker \varphi)_x = \ker \varphi_x$ *and* $(\operatorname{coker} \varphi)_x = \operatorname{coker} \varphi_x$. *A sequence of sheaves is exact if and only if it is exact on all stalks. The functor $\Gamma(U, -)$ is left exact but not exact in general.*

Proof. Sums of morphisms and finite direct sums $(\mathcal{F} \oplus \mathcal{G})(U) = \mathcal{F}(U) \oplus \mathcal{G}(U)$ make $\mathrm{Ab}(X)$ additive. The presheaf kernel is a sheaf and is a kernel in $\mathrm{Ab}(X)$. By Theorem 25.3.1(2), the sheafified presheaf cokernel is a cokernel. Stalks are directed colimits, which are exact (Lemma 23.5.1), and sheafification does not change stalks; this gives the formulas for stalks. If φ is a monomorphism, the canonical morphism from $\mathcal{F}$ to the kernel of its cokernel is bijective on stalks, because Ab is abelian; so it is an isomorphism by Proposition 25.2.4; similarly for epimorphisms. Images and exactness are defined by kernels and cokernels, so they are computed on stalks. Left exactness of Γ holds because kernels are computed sectionwise.

For the failure of right exactness, let $X = \mathbb{R}$, $p \neq q$ in X, and consider $\mathbb{Z}_X \to p_*\mathbb{Z} \oplus q_*\mathbb{Z}$, sending a locally constant function to its values at p and q (when defined). On stalks it is surjective: at p it is $\mathbb{Z} \to \mathbb{Z}$, the identity, and at points $x \neq p, q$ the target stalk is 0, since x has a neighbourhood containing neither p nor q. On global sections it is $\mathbb{Z} \to \mathbb{Z} \oplus \mathbb{Z}$, $n \mapsto (n, n)$, because $\mathbb{R}$ is connected, and this is not surjective. □

Counterexample 25.3.3. Surjectivity on stalks is a local lifting property, and global sections can fail to lift for topological reasons. Let $T = \mathbb{R}/\mathbb{Z}$ with quotient map $q\colon \mathbb{R} \to T$. The covering $p\colon \mathbb{R} \to S^1$ of Proposition 19.4.5 induces a continuous bijection $\mathbb{R}/4\mathbb{Z} \to S^1$ from a compact space to a Hausdorff space, hence a homeomorphism (Proposition 18.6.3), so

$T \cong \mathbb{R}/4\mathbb{Z} \cong S^1$ and q is a covering map. On any space X, let $\mathcal{C}_{\mathbb{R}}$ and $\mathcal{C}_T$ be the sheaves of continuous maps to $\mathbb{R}$ and to the abelian group T, and consider

$$0 \to \mathbb{Z}_X \to \mathcal{C}_{\mathbb{R}} \xrightarrow{f \mapsto q \circ f} \mathcal{C}_T \to 0.$$

The kernel of $f \mapsto q \circ f$ consists of the continuous maps to $\mathbb{Z}$, that is, $\mathbb{Z}_X$. On stalks the map is surjective: a continuous $g : W \to T$ near x takes a small neighbourhood of x into an evenly covered open set, over which q has a continuous inverse on each sheet. So the sequence is exact (Proposition 25.3.2). But for $X = T$, the identity $\mathrm{id}_T \in \mathcal{C}_T(T)$ is not of the form $q \circ f$: a continuous $f : T \to \mathbb{R}$ with $q \circ f = \mathrm{id}$ would be a lift of id_T through q, which by the lifting criterion (Proposition 19.6.1) requires $\pi_1(T) \subseteq q_*\pi_1(\mathbb{R}) = 0$, whereas $\pi_1(T) \cong \pi_1(S^1) \cong \mathbb{Z}$ (Theorem 19.4.6). So $\Gamma(T, -)$ is not right exact on this sequence; the obstruction will reappear as the nonzero group $H^1(S^1, \mathbb{Z}) \cong \mathbb{Z}$ (Chapter 26).

25.4 Direct and inverse images

Definition 25.4.1. Let $f : X \to Y$ be continuous. The *direct image* of a sheaf $\mathcal{F}$ on X is the sheaf $f_*\mathcal{F}(V) = \mathcal{F}(f^{-1}V)$ on Y. The *inverse image* of a sheaf $\mathcal{G}$ on Y is the sheafification $f^{-1}\mathcal{G}$ of the presheaf $f_p^{-1}\mathcal{G}(U) = \operatorname{colim}_{V \supseteq f(U)} \mathcal{G}(V)$, the colimit over open $V \supseteq f(U)$ directed by reverse inclusion. For $i : Z \to X$ the inclusion of a subspace, $\mathcal{F}|_Z = i^{-1}\mathcal{F}$ is the *restriction*; for Z open, $\mathcal{F}|_Z(W) = \mathcal{F}(W)$.

Proposition 25.4.2. *1. $(f^{-1}\mathcal{G})_x \cong \mathcal{G}_{f(x)}$; hence f^{-1} is exact on sheaves of abelian groups. The functor f_* is left exact.*

2. There is a bijection $\mathrm{Hom}_{\mathrm{Sh}(X)}(f^{-1}\mathcal{G}, \mathcal{F}) \cong \mathrm{Hom}_{\mathrm{Sh}(Y)}(\mathcal{G}, f_*\mathcal{F})$, natural in $\mathcal{F}$ and $\mathcal{G}$: f^{-1} is left adjoint to f_*.

3. $(g \circ f)_* = g_* \circ f_*$ and $(g \circ f)^{-1} \cong f^{-1} \circ g^{-1}$.

Proof. (1) The pairs (U, V) with $x \in U$ and $V \supseteq f(U)$ map cofinally to the open neighbourhoods V of $f(x)$ (take $U = f^{-1}V$), so $(f_p^{-1}\mathcal{G})_x = \operatorname{colim}_{V \ni f(x)} \mathcal{G}(V)$ by Lemma 23.5.1, and sheafification preserves stalks. Exactness follows from Proposition 25.3.2. Kernels of sheaves are computed sectionwise, so f_* preserves them.

(2) By Theorem 25.3.1(2), morphisms $f^{-1}\mathcal{G} \to \mathcal{F}$ are morphisms of presheaves $f_p^{-1}\mathcal{G} \to \mathcal{F}$, that is, families of maps $\mathcal{G}(V) \to \mathcal{F}(U)$ for $V \supseteq f(U)$, compatible with restrictions in U and V. Such a family determines maps $\mathcal{G}(V) \to \mathcal{F}(f^{-1}V)$ (take $U = f^{-1}V$), compatible with restrictions, that is, a morphism $\mathcal{G} \to f_*\mathcal{F}$. Conversely a morphism $\psi : \mathcal{G} \to f_*\mathcal{F}$ gives $\mathcal{G}(V) \xrightarrow{\psi_V} \mathcal{F}(f^{-1}V) \to \mathcal{F}(U)$ by restriction, as $U \subseteq f^{-1}V$. These constructions are mutually inverse and natural.

(3) The first equality is clear; the second follows from (2) and uniqueness of adjoints (Proposition 6.10.3). □

Definition 25.4.3. Let $j : U \to X$ be the inclusion of an open subset and $\mathcal{F}$ a sheaf of abelian groups on U. The *extension by zero* $j_!\mathcal{F}$ is the sheafification of the presheaf $W \mapsto \mathcal{F}(W)$ if $W \subseteq U$ and $W \mapsto 0$ otherwise.

Proposition 25.4.4. *$(j_!\mathcal{F})_x = \mathcal{F}_x$ for $x \in U$ and 0 for $x \notin U$. If $Z = X \setminus U$ with inclusion i, then for every sheaf of abelian groups $\mathcal{F}$ on X there is a short exact sequence $0 \to j_!(\mathcal{F}|_U) \to \mathcal{F} \to i_*(\mathcal{F}|_Z) \to 0$.*

Proof. For $x \in U$ the open neighbourhoods contained in U are cofinal; for $x \notin U$ no neighbourhood is contained in U. The first map is induced, via Theorem 25.3.1(2), by the inclusions $\mathcal{F}(W) \to \mathcal{F}(W)$ for $W \subseteq U$; the second is the unit $\mathcal{F} \to i_* i^{-1}\mathcal{F}$ of the adjunction. On stalks at $x \in U$, the sequence is $0 \to \mathcal{F}_x \to \mathcal{F}_x \to 0 \to 0$, since x has a neighbourhood missing the closed set Z. At $z \in Z$, the open subsets $W \cap Z$ are cofinal among neighbourhoods of z in Z, so $(i_* i^{-1}\mathcal{F})_z = (i^{-1}\mathcal{F})_z = \mathcal{F}_z$, and the sequence is $0 \to 0 \to \mathcal{F}_z \to \mathcal{F}_z \to 0$. □

25.5 Locally constant sheaves and local systems

Definition 25.5.1. A sheaf $\mathcal{F}$ of sets is *locally constant* if every point has an open neighbourhood U with $\mathcal{F}|_U$ isomorphic to a constant sheaf A_U. A *local system* of K-vector spaces (for a field K) is a locally constant sheaf of K-vector spaces whose stalks are finite-dimensional; local systems of abelian groups or modules are defined similarly.

Proposition 25.5.2. *Let $\mathcal{F}$ be a sheaf of sets on X. The* étalé space $E_{\mathcal{F}} = \bigsqcup_x \mathcal{F}_x$, *with the topology whose basis is the sets $\{s_x : x \in U\}$ for $s \in \mathcal{F}(U)$, has a local homeomorphism $p\colon E_{\mathcal{F}} \to X$, and $\mathcal{F}$ is isomorphic to the sheaf of sections of p. If $\mathcal{F}$ is locally constant and X is locally connected, p is a covering map (except that fibres may be empty), and conversely the sheaf of sections of such a covering is locally constant.*

Proof. If $s_x = t_x$ for $s \in \mathcal{F}(U)$, $t \in \mathcal{F}(V)$, the two basic sets contain the basic set of $s|_W$ for some $W \ni x$; so these sets form a basis, and p maps the basic set of s homeomorphically onto U, with inverse $\hat{s}\colon x \mapsto s_x$. The map $s \mapsto \hat{s}$ from $\mathcal{F}(U)$ to continuous sections over U is injective by Proposition 25.2.4(1); it is surjective, because a continuous section σ is locally of the form $\hat{s}$ (near x, σ lies in the basic set of some s with $s_x = \sigma(x)$), and these local s glue. If $\mathcal{F}|_U \cong A_U$ with U connected, then $p^{-1}(U) \cong U \times A$ with A discrete, because the germs of the constant sections $a \in A$ give disjoint open sets covering $p^{-1}(U)$. Conversely, over a connected evenly covered open set, sections of a covering correspond to locally constant choices of sheets. □

Theorem 25.5.3. *Let X be path-connected, locally path-connected and semilocally simply connected, and $x \in X$. Taking the stalk at x, with the monodromy action, gives equivalences of categories between*

1. *locally constant sheaves of sets on X and sets with a right action of $\pi_1(X, x)$;*
2. *local systems of K-vector spaces on X and finite-dimensional right $K[\pi_1(X, x)]$-modules, that is, representations $\rho\colon \pi_1(X, x)^{\mathrm{op}} \to \mathrm{GL}(\mathcal{F}_x)$.*

Sketch of proof. By Proposition 25.5.2, locally constant sheaves correspond to covering spaces (with possibly empty fibres), and morphisms of sheaves to maps of coverings. A covering is the disjoint union of its components, which are connected coverings of X, and the fibre over x with its monodromy action (Corollary 19.4.4) is a right $\pi_1(X, x)$-set whose orbits correspond to the components. For connected coverings, the classification theorem (Theorem 19.6.6) identifies isomorphism classes with transitive π_1-sets $H\backslash\pi_1(X, x)$, and the lifting criterion (Proposition 19.6.1) identifies maps of coverings with equivariant maps of fibres; this gives (1). The omitted verification is that these identifications are functorial; see [Sza09, Chapter 2]. For (2), a local system is a locally constant sheaf of sets with a K-vector space structure on the stalks compatible with monodromy, and the monodromy action is then K-linear. □

Example 25.5.4. 1. On a simply connected space every local system is constant.

2. On S^1, the rank one local systems of $\mathbb{C}$-vector spaces correspond to $\lambda \in \mathbb{C}^\times$, the monodromy around the generator of $\pi_1(S^1) \cong \mathbb{Z}$. For $\lambda \neq 1$ the local system $\mathcal{L}_\lambda$ has no nonzero global sections, since a global section is a vector fixed by monodromy. The real local system with monodromy -1 is the sheaf of locally constant sections of the Möbius band, viewed as a line bundle over S^1.

3. For a manifold M, the *orientation sheaf* or_M, with stalks $H_n(M \mid x; \mathbb{Z})$, is the local system of rank one associated with the orientation double covering (Proposition 23.3.2); it is constant if and only if M is orientable.

4. For a family of spaces $f : E \to B$ that is locally trivial, the cohomology groups of the fibres form local systems $R^k f_* \mathbb{Z}$ on B (Chapter 26); their monodromy is a central object in the theory of variations of Hodge structure (Chapter 70).

25.6 Ringed spaces and sheaves of modules

Definition 25.6.1. A *ringed space* is a pair $(X, \mathcal{O}_X)$ of a space and a sheaf of commutative rings. It is *locally ringed* if all stalks $\mathcal{O}_{X,x}$ are local rings. A *morphism* $(f, f^\#) \colon (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ is a continuous map f with a morphism of sheaves of rings $f^\# \colon \mathcal{O}_Y \to f_* \mathcal{O}_X$; for locally ringed spaces one requires the induced maps $\mathcal{O}_{Y,f(x)} \to \mathcal{O}_{X,x}$ to be local homomorphisms. An *$\mathcal{O}_X$-module* is a sheaf of abelian groups $\mathcal{F}$ with $\mathcal{O}_X(U)$-module structures on $\mathcal{F}(U)$ compatible with restrictions.

Example 25.6.2. A space with its sheaf of continuous real functions, a smooth manifold with smooth functions (Chapter 33), a complex manifold with holomorphic functions (Chapter 44) and a scheme (Chapter 54) are locally ringed spaces: in each case the germs vanishing at x form the unique maximal ideal of the stalk, since a germ not vanishing at x is invertible near x.

Definition 25.6.3. Let $\mathcal{F}, \mathcal{G}$ be $\mathcal{O}_X$-modules. The *tensor product* $\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{G}$ is the sheafification of $U \mapsto \mathcal{F}(U) \otimes_{\mathcal{O}_X(U)} \mathcal{G}(U)$. The sheaf $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})$ has sections over U the morphisms $\mathcal{F}|_U \to \mathcal{G}|_U$ of $\mathcal{O}_U$-modules, and $\mathcal{F}^\vee = \mathcal{H}om(\mathcal{F}, \mathcal{O}_X)$ is the *dual*. An $\mathcal{O}_X$-module is *locally free of rank r* if every point has an open neighbourhood U with $\mathcal{F}|_U \cong \mathcal{O}_U^{\oplus r}$, and *invertible* if it is locally free of rank 1. For a morphism f of ringed spaces and an $\mathcal{O}_Y$-module $\mathcal{G}$, the *pullback* is $f^*\mathcal{G} = f^{-1}\mathcal{G} \otimes_{f^{-1}\mathcal{O}_Y} \mathcal{O}_X$.

Proposition 25.6.4. *1. $\mathcal{H}om(\mathcal{F}, \mathcal{G})$ is a sheaf, and $(\mathcal{F} \otimes \mathcal{G})_x \cong \mathcal{F}_x \otimes_{\mathcal{O}_{X,x}} \mathcal{G}_x$.*

2. *If $\mathcal{E}$ and $\mathcal{E}'$ are locally free of ranks r and r', then $\mathcal{E} \otimes \mathcal{E}'$ is locally free of rank rr', $\mathcal{E}^\vee$ is locally free of rank r, and the evaluation map $\mathcal{E} \otimes \mathcal{E}^\vee \to \mathcal{O}_X$ is an isomorphism if $r = 1$.*

3. *The isomorphism classes of invertible sheaves form an abelian group* $\mathrm{Pic}(X)$ *under $\otimes$, with identity $\mathcal{O}_X$ and inverse $\mathcal{L}^\vee$.*

Proof. (1) Morphisms defined on the members of an open cover and agreeing on overlaps glue uniquely, because sections of $\mathcal{G}$ do. For the stalk, sheafification does not change stalks, so it suffices to compare $\operatorname{colim}_{U \ni x} \mathcal{F}(U) \otimes_{\mathcal{O}_X(U)} \mathcal{G}(U)$ with $\mathcal{F}_x \otimes_{\mathcal{O}_{X,x}} \mathcal{G}_x$. The map $[s \otimes t] \mapsto s_x \otimes t_x$ is well defined; an inverse sends $s_x \otimes t_x$ to the class of $s|_W \otimes t|_W$ on a common neighbourhood W, which is well defined because every relation defining the tensor product over $\mathcal{O}_{X,x}$ involves finitely many germs and already holds over some neighbourhood of x [Har77, Chapter II, Section 5].

(2) All statements are local, so we may assume $\mathcal{E} = \mathcal{O}^r$ and $\mathcal{E}' = \mathcal{O}^{r'}$. Then $\mathcal{O}^r \otimes \mathcal{O}^{r'} \cong \mathcal{O}^{rr'}$ (the presheaf tensor product is already a sheaf in this case), $\mathcal{H}om(\mathcal{O}^r, \mathcal{O}) \cong \mathcal{O}^r$, and for

$r = 1$ evaluation $\mathcal{O} \otimes \mathcal{O} \to \mathcal{O}$ is multiplication, an isomorphism. Since the evaluation map is a globally defined morphism, and being an isomorphism can be checked on stalks (Proposition 25.2.4), it is an isomorphism.

(3) Tensor product is associative and commutative up to natural isomorphism, $\mathcal{O}_X \otimes \mathcal{L} \cong \mathcal{L}$, and (2) gives inverses. □

Remark 25.6.5. If $E \to X$ is a (real or complex, topological, smooth or holomorphic) vector bundle of rank r, its sheaf of sections is a locally free module of rank r over the corresponding sheaf of functions, and every locally free sheaf arises in this way, uniquely up to isomorphism (Chapter 35). Under this correspondence, $\mathrm{Pic}(X)$ is the group of line bundles; for a complex manifold it is computed by sheaf cohomology via the exponential sequence (Chapter 45).

25.7 Exercises

Exercise 25.7.1. Show that the sheafification of the constant presheaf with value A is the constant sheaf A_X of locally constant functions, and that $A_X = \pi^{-1}A$ for $\pi\colon X \to \mathrm{pt}$.

Solution. The stalks of the constant presheaf are all A, and a section of the sheafification is a function $U \to A$ locally equal to a constant, that is, a locally constant function. For the second statement, $\pi_p^{-1}A(U) = A$ for $U \neq \emptyset$. □

Exercise 25.7.2. Let $i\colon \{x\} \to X$. Show that $x_*A = i_*A$ and $\mathrm{Hom}(\mathcal{F}, x_*A) \cong \mathrm{Hom}(\mathcal{F}_x, A)$ for every sheaf $\mathcal{F}$ of abelian groups.

Solution. The first statement is the definition. By Proposition 25.4.2(2) and (1), $\mathrm{Hom}(\mathcal{F}, i_*A) \cong \mathrm{Hom}(i^{-1}\mathcal{F}, A) = \mathrm{Hom}(\mathcal{F}_x, A)$, since a sheaf on a point is a single group. □

Exercise 25.7.3. Give an example of a continuous map f and a sheaf $\mathcal{F}$ such that $(f_*\mathcal{F})_y$ is not isomorphic to the global sections of $\mathcal{F}$ on the fibre $f^{-1}(y)$.

Exercise 25.7.4. Let $X = \mathbb{C} \setminus \{0\}$ with the sheaf $\mathcal{O}$ of holomorphic functions and $\mathcal{O}^\times$ of nowhere vanishing ones. Accepting that holomorphic functions have local logarithms of nonvanishing functions but z has no global logarithm, show that $\exp\colon \mathcal{O} \to \mathcal{O}^\times$, $f \mapsto e^{2\pi i f}$, is an epimorphism of sheaves but not surjective on global sections, and identify its kernel.

Exercise 25.7.5. For $j\colon U \to X$ open, show that $j_!$ is left adjoint to j^{-1} on sheaves of abelian groups, and that j^{-1} is left adjoint to j_*.

Chapter 26

Sheaf Cohomology

26.1 Introduction

The global sections functor $\Gamma(X, -)$ is left exact but not exact (Proposition 25.3.2), and sheaf cohomology $H^i(X, \mathcal{F})$ is its right derived functor. It can be computed by several kinds of acyclic resolutions: flasque, soft or fine sheaves (Theorem 26.4.5), Čech complexes of acyclic covers (Theorem 26.5.3), and hypercohomology of complexes. On reasonable spaces the cohomology of a constant sheaf is singular cohomology (Theorem 26.6.1); on a manifold the de Rham complex is a fine resolution of the constant sheaf, which gives the de Rham theorem (Chapter 37). References: [Har77, Chapter III], [God58], [Bre97], [KS90] and [Voi02b, Chapter 4].

Prerequisites. Chapter 25 (Sheaves on Topological Spaces), Chapter 16 (Spectral Sequences), Chapter 17 (Derived Categories) and Chapter 22 (Singular Cohomology).

On the way to the Hodge conjecture. Needed: cohomology as a derived functor, flasque, soft and fine sheaves, Čech cohomology (for line bundles and the exponential sequence), the comparison with singular cohomology and hypercohomology. Cohomology with compact supports (Section 26.8) can be postponed.

26.2 Cohomology as a derived functor

Lemma 26.2.1. *Let $L\colon \mathcal{B} \to \mathcal{A}$ be an exact functor between abelian categories with right adjoint $R\colon \mathcal{A} \to \mathcal{B}$. Then R preserves injective objects. In particular f_* preserves injective sheaves for every continuous f, and so does restriction j^{-1} to an open subset $j\colon U \to X$.*

Proof. For I injective, $\mathrm{Hom}_{\mathcal{B}}(-, R(I)) \cong \mathrm{Hom}_{\mathcal{A}}(L(-), I)$ is a composite of exact functors, hence exact. For f_* use Proposition 25.4.2. For j^{-1} we show that $j_!$ is an exact left adjoint: a morphism $j_!\mathcal{F} \to \mathcal{G}$ is, by Theorem 25.3.1, a compatible family of maps $\mathcal{F}(W) \to \mathcal{G}(W)$ for $W \subseteq U$, that is, a morphism $\mathcal{F} \to \mathcal{G}|_U$; and $j_!$ is exact on stalks (Proposition 25.4.4). □

Theorem 26.2.2. *The category* Ab(X) *has enough injectives, and so does the category of $\mathcal{O}_X$-modules on a ringed space.*

Proof. For each x embed $\mathcal{F}_x$ into an injective abelian group I_x (Theorem 15.5.4). The skyscraper sheaf x_*I_x is injective, since $\mathrm{Hom}(\mathcal{G}, x_*I_x) \cong \mathrm{Hom}(\mathcal{G}_x, I_x)$ (Exercise 25.7.2) is exact in $\mathcal{G}$. A product of injective objects is injective, and $\mathcal{F} \to \prod_x x_*I_x$ is a monomorphism, being injective on stalks. For $\mathcal{O}_X$-modules use injective $\mathcal{O}_{X,x}$-modules instead. □

Definition 26.2.3. The *sheaf cohomology* groups are $H^i(X, \mathcal{F}) = R^i\Gamma(X, -)(\mathcal{F})$ (Definition 15.6.4). For a complex $\mathcal{K}^\bullet$ of sheaves, bounded below, the *hypercohomology* is $\mathbb{H}^i(X, \mathcal{K}^\bullet) =$

$H^i(R\Gamma(X, \mathcal{K}^\bullet))$ (Definition 17.4.4). For a continuous $f\colon X \to Y$, the *higher direct images* are $R^i f_* \mathcal{F}$.

Remark 26.2.4. For an $\mathcal{O}_X$-module $\mathcal{F}$, derived functors computed in $\mathcal{O}_X$-modules and in $\mathrm{Ab}(X)$ agree, because injective $\mathcal{O}_X$-modules are flasque (Lemma 26.3.2 applies verbatim with $j_!\mathcal{O}_U \to \mathcal{O}_X$) and flasque sheaves are acyclic in both settings.

26.3 Flasque sheaves

Definition 26.3.1. A sheaf $\mathcal{F}$ is *flasque* if all restriction maps $\mathcal{F}(U) \to \mathcal{F}(V)$ are surjective.

Lemma 26.3.2. *Injective sheaves of abelian groups are flasque. Direct images and restrictions to open subsets of flasque sheaves are flasque, and so are products.*

Proof. Let I be injective and $V \subseteq U$ open, with inclusions j_V, j_U into X. The morphism $j_{V!}\mathbb{Z}_V \to j_{U!}\mathbb{Z}_U$ is injective on stalks, so $\mathrm{Hom}(j_{U!}\mathbb{Z}_U, I) \to \mathrm{Hom}(j_{V!}\mathbb{Z}_V, I)$ is surjective. By the adjunction in the proof of Lemma 26.2.1, $\mathrm{Hom}(j_{U!}\mathbb{Z}_U, I) = \mathrm{Hom}(\mathbb{Z}_U, I|_U) = I(U)$, a morphism from the constant sheaf being determined by the image of 1; so $I(U) \to I(V)$ is surjective. The other statements are immediate from the definitions. □

Proposition 26.3.3. *Let $0 \to \mathcal{F}' \to \mathcal{F} \xrightarrow{\pi} \mathcal{F}'' \to 0$ be exact with $\mathcal{F}'$ flasque. Then $\mathcal{F}(U) \to \mathcal{F}''(U)$ is surjective for all U. If also $\mathcal{F}$ is flasque, so is $\mathcal{F}''$. Flasque sheaves are Γ-acyclic, so $H^i(X, \mathcal{F})$ can be computed with flasque resolutions.*

Proof. We may take $U = X$. Let $s \in \mathcal{F}''(X)$, and consider pairs (V, t) with V open, $t \in \mathcal{F}(V)$ and $\pi(t) = s|_V$, ordered by extension. A chain has an upper bound by gluing, and it is nonempty, since s lifts locally. Let (V, t) be maximal and suppose $x \notin V$. Choose $W \ni x$ and $t' \in \mathcal{F}(W)$ lifting $s|_W$. On $V \cap W$, $t - t'$ lies in $\mathcal{F}'(V \cap W)$, which extends to $u \in \mathcal{F}'(X)$ since $\mathcal{F}'$ is flasque. Then t and $t' + u|_W$ agree on $V \cap W$ and glue to a lift over $V \cup W$, contradicting maximality. If $\mathcal{F}$ is flasque and $s'' \in \mathcal{F}''(V)$, lift it to $\mathcal{F}(V)$, extend to $\mathcal{F}(X)$ and map to $\mathcal{F}''(X)$.

Let $\mathcal{F}$ be flasque and embed it into an injective I with cokernel $\mathcal{G}$, which is flasque by the above and Lemma 26.3.2. The long exact sequence gives $H^1(X, \mathcal{F}) = \mathrm{coker}(I(X) \to \mathcal{G}(X)) = 0$ and $H^i(X, \mathcal{F}) \cong H^{i-1}(X, \mathcal{G})$ for $i \geq 2$, which vanishes by induction on i for all flasque sheaves simultaneously. The last statement is Proposition 15.6.6. □

Example 26.3.4. For every sheaf $\mathcal{F}$, the sheaf $C^0(\mathcal{F}) = \prod_x x_* \mathcal{F}_x$ of possibly discontinuous sections is flasque, and $\mathcal{F} \to C^0(\mathcal{F})$ is injective. Repeating with the cokernel gives the *Godement resolution*, a canonical flasque resolution, functorial and exact in $\mathcal{F}$.

26.4 Soft and fine sheaves

In this section X is paracompact Hausdorff. For a subset $Z \subseteq X$ we write $\mathcal{F}(Z) = \Gamma(Z, \mathcal{F}|_Z)$; by Proposition 25.5.2 this is the set of continuous sections over Z of the étalé space of $\mathcal{F}$. Sections over the members of a locally finite closed cover of Z that agree on overlaps glue, by the pasting lemma applied locally.

Lemma 26.4.1. *Let $Z \subseteq X$ be closed. Every $s \in \mathcal{F}(Z)$ extends to a section over some open neighbourhood of Z.*

Proof. Each $z \in Z$ has an open neighbourhood W_z in X and $t_z \in \mathcal{F}(W_z)$ with germs $s(y)$ at all $y \in W_z \cap Z$. Take a locally finite open refinement $(U_i)_{i\in I}$ of the cover $\{W_z\} \cup \{X \setminus Z\}$, choosing for each i either a section $t_i = t_z|_{U_i}$ (first kind) or $U_i \subseteq X \setminus Z$ (second kind), and closed sets $\overline{V_i} \subseteq U_i$ with (V_i) still covering (Lemma 18.10.4, Proposition 18.10.3). For $x \in X$ let $J(x) = \{i : x \in \overline{V_i}\}$, a finite set. Let W be the set of x such that $J(x)$ contains only indices of the first kind and the germs $(t_i)_x$, $i \in J(x)$, all agree.

$Z \subseteq W$, since for $z \in Z$ all $i \in J(z)$ are of the first kind and $(t_i)_z = s(z)$. W is open: for $x \in W$ choose an open $N \ni x$ that meets only finitely many $\overline{V_i}$, avoids those with $i \notin J(x)$, lies in $\bigcap_{i\in J(x)} U_i$, and on which the sections t_i, $i \in J(x)$, agree; then $J(y) \subseteq J(x)$ for $y \in N$, so $N \subseteq W$. On such an $N = N_x$, put $t^{(x)} = t_i|_{N_x}$ for any $i \in J(x)$ (nonempty, since the V_i cover). At $y \in N_x \cap N_{x'}$ both $t^{(x)}$ and $t^{(x')}$ have the germ $(t_k)_y$ for $k \in J(y)$, so they agree, and they glue to $t \in \mathcal{F}(W)$ with $t_z = s(z)$ on Z. □

Definition 26.4.2. A sheaf $\mathcal{F}$ on X is *soft* if $\mathcal{F}(X) \to \mathcal{F}(Z)$ is surjective for every closed Z. The *support* of an endomorphism η of $\mathcal{F}$ is the closure of $\{x : \eta_x \neq 0\}$. A sheaf of abelian groups is *fine* if for every locally finite open cover (U_i) there are endomorphisms η_i with $\operatorname{supp} \eta_i \subseteq U_i$ and $\sum_i \eta_i = \mathrm{id}$ (a *partition of unity* of $\mathcal{F}$).

Example 26.4.3. The sheaf C_X of continuous real functions is fine, by partitions of unity (Theorem 18.10.6): take η_i to be multiplication by ψ_i. More generally every sheaf of modules over C_X is fine, and on a smooth manifold every module over the sheaf of smooth functions is fine, using smooth partitions of unity (Chapter 33). The constant sheaf $\mathbb{Z}_X$ on a connected space with more than one point is not soft.

Lemma 26.4.4. *1. Flasque sheaves and fine sheaves are soft.*

2. If $0 \to \mathcal{F}' \to \mathcal{F} \xrightarrow{\pi} \mathcal{F}'' \to 0$ is exact and $\mathcal{F}'$ is soft, then $\mathcal{F}(X) \to \mathcal{F}''(X)$ is surjective.

3. If moreover $\mathcal{F}$ is soft, then $\mathcal{F}''$ is soft.

Proof. (1) Let $s \in \mathcal{F}(Z)$ and extend it to an open $W \supseteq Z$ by Lemma 26.4.1. If $\mathcal{F}$ is flasque, extend further to X. If $\mathcal{F}$ is fine, take $\eta_1 + \eta_2 = \mathrm{id}$ for the cover $\{W, X \setminus Z\}$. The section $\eta_1(s)$ of $\mathcal{F}(W)$ vanishes on $W \setminus \operatorname{supp} \eta_1$, so it glues with 0 on $X \setminus \operatorname{supp} \eta_1$ to a global section t; at $z \in Z$, $t_z = s_z - (\eta_2)_z(s_z) = s_z$ since $z \notin \operatorname{supp} \eta_2$.

(2) Choose a locally finite open cover (U_i) with lifts $s_i \in \mathcal{F}(U_i)$ of $s|_{U_i}$ for a given $s \in \mathcal{F}''(X)$, and closed $\overline{V_i} \subseteq U_i$ covering X. Consider pairs (J, t) with $J \subseteq I$ and $t \in \mathcal{F}(Z_J)$ lifting s, where $Z_J = \bigcup_{i\in J} \overline{V_i}$, which is closed (Lemma 18.10.2). Chains have upper bounds by gluing along the locally finite closed cover, so Zorn's lemma gives a maximal (J, t). If $i \notin J$, the difference $t - s_i$ on $Z_J \cap \overline{V_i}$ is a section of $\mathcal{F}'$ (its image under π is 0), which extends to $u \in \mathcal{F}'(X)$. Then t and $s_i + u$ agree on $Z_J \cap \overline{V_i}$ and glue to a lift over $Z_{J\cup\{i\}}$, a contradiction. So $J = I$.

(3) A closed subspace Z is paracompact Hausdorff, the restricted sequence on Z is exact, and $\mathcal{F}'|_Z$ is soft. By (2) applied on Z, $\mathcal{F}(Z) \to \mathcal{F}''(Z)$ is surjective, and $\mathcal{F}(X) \to \mathcal{F}(Z)$ is surjective. □

Theorem 26.4.5. *On a paracompact Hausdorff space, soft sheaves, in particular fine sheaves, are Γ-acyclic. Hence cohomology can be computed with soft or fine resolutions.*

Proof. Identical to the proof of Proposition 26.3.3, using Lemma 26.4.4 and the fact that injective sheaves are flasque, hence soft. □

Corollary 26.4.6. *Let X be paracompact Hausdorff. Then $H^i(X, \mathcal{F}) = 0$ for $i > 0$ for every sheaf of C_X-modules, for instance the sheaf of sections of a real vector bundle.*

Proof. Such a sheaf is fine (Example 26.4.3) and is its own resolution. □

26.5 Čech cohomology

Definition 26.5.1. Let $\mathcal{U} = (U_i)_{i\in I}$ be an open cover of X and $\mathcal{F}$ a presheaf of abelian groups. Write $U_{i_0\cdots i_p} = U_{i_0} \cap \cdots \cap U_{i_p}$. An *alternating Čech p-cochain* is a family $\alpha = (\alpha_{i_0\cdots i_p})$, indexed by all $(i_0, \ldots, i_p) \in I^{p+1}$, with $\alpha_{i_0\cdots i_p} \in \mathcal{F}(U_{i_0\cdots i_p})$, which changes sign when two indices are exchanged and vanishes when two indices are equal. They form a group $\check{C}^p(\mathcal{U}, \mathcal{F})$, with differential

$$(d\alpha)_{i_0\cdots i_{p+1}} = \sum_{k=0}^{p+1} (-1)^k \alpha_{i_0\cdots \widehat{i_k}\cdots i_{p+1}}|_{U_{i_0\cdots i_{p+1}}}.$$

Its cohomology is the *Čech cohomology* $\check{H}^p(\mathcal{U}, \mathcal{F})$. Choosing a well-ordering of I, $\check{C}^p(\mathcal{U}, \mathcal{F}) \cong \prod_{i_0<\cdots<i_p} \mathcal{F}(U_{i_0\cdots i_p})$. For a sheaf, $\check{H}^0(\mathcal{U}, \mathcal{F}) = \mathcal{F}(X)$ by the sheaf axioms. The *sheafified Čech complex* $\check{\mathcal{C}}^p(\mathcal{U}, \mathcal{F})$ is the sheaf $V \mapsto \check{C}^p(\mathcal{U} \cap V, \mathcal{F}|_V)$, with augmentation $\mathcal{F} \to \check{\mathcal{C}}^0$ given by restriction.

Lemma 26.5.2. *For every sheaf $\mathcal{F}$ and open cover $\mathcal{U}$, the sequence $0 \to \mathcal{F} \to \check{\mathcal{C}}^0(\mathcal{U}, \mathcal{F}) \to \check{\mathcal{C}}^1(\mathcal{U}, \mathcal{F}) \to \cdots$ is exact. If $\mathcal{F}$ is flasque, then $\check{H}^p(\mathcal{U}, \mathcal{F}) = 0$ for $p > 0$.*

Proof. Let $x \in X$ and choose j with $x \in U_j$. For open $V \subseteq U_j$ define $k\colon \check{C}^p(\mathcal{U} \cap V, \mathcal{F}) \to \check{C}^{p-1}(\mathcal{U} \cap V, \mathcal{F})$ by $(k\alpha)_{i_0\cdots i_{p-1}} = \alpha_{j i_0\cdots i_{p-1}}$, which makes sense since $V \cap U_{j i_0\cdots i_{p-1}} = V \cap U_{i_0\cdots i_{p-1}}$, and k = restriction to $V \cap U_j = V$ in degree 0. Then $(dk\alpha)_{i_0\cdots i_p} = \sum_k (-1)^k \alpha_{j i_0\cdots \widehat{i_k}\cdots i_p}$ and $(kd\alpha)_{i_0\cdots i_p} = \alpha_{i_0\cdots i_p} - \sum_k (-1)^k \alpha_{j i_0\cdots \widehat{i_k}\cdots i_p}$, so $dk + kd = \mathrm{id}$, and similarly in degree 0 with the augmentation. Passing to the colimit over $V \ni x$, the complex of stalks is contractible, hence exact.

If $\mathcal{F}$ is flasque, each $\check{\mathcal{C}}^p(\mathcal{U}, \mathcal{F})$ is a product of sheaves $(j_{i_0\cdots i_p})_*(\mathcal{F}|_{U_{i_0\cdots i_p}})$, hence flasque (Lemma 26.3.2); so the resolution is flasque, its global sections $\check{C}^\bullet(\mathcal{U}, \mathcal{F})$ compute $H^\bullet(X, \mathcal{F})$ (Proposition 26.3.3), and this vanishes in positive degrees. □

Theorem 26.5.3 (Leray)**.** *Let $\mathcal{U}$ be an open cover of X such that $H^q(U_{i_0\cdots i_p}, \mathcal{F}) = 0$ for all $q > 0$ and all finite intersections. Then $\check{H}^p(\mathcal{U}, \mathcal{F}) \cong H^p(X, \mathcal{F})$ for all p.*

Proof. Let $\mathcal{F} \to I^\bullet$ be an injective resolution and consider the first-quadrant double complex $C^{p,q} = \check{C}^p(\mathcal{U}, I^q)$. For fixed q, the row $\check{C}^\bullet(\mathcal{U}, I^q)$ is exact in positive degrees with kernel $I^q(X)$ in degree 0, by Lemmas 26.5.2 and 26.3.2. For fixed p, the column is $\prod_{i_0<\cdots<i_p} I^\bullet(U_{i_0\cdots i_p})$; since $I^\bullet|_U$ is an injective resolution of $\mathcal{F}|_U$ (Lemma 26.2.1) and products of abelian groups are exact, its cohomology is $\prod H^q(U_{i_0\cdots i_p}, \mathcal{F})$, which is 0 for $q > 0$ and $\check{C}^p(\mathcal{U}, \mathcal{F})$ for $q = 0$. By Lemma 15.7.2, applied once to rows and once to columns, both $\Gamma(X, I^\bullet)$ and $\check{C}^\bullet(\mathcal{U}, \mathcal{F})$ are quasi-isomorphic to the total complex. Taking cohomology gives the theorem. □

Remark 26.5.4. Refinements of covers induce maps on Čech cohomology, well defined up to homotopy, and the colimit over all covers is the Čech cohomology $\check{H}^p(X, \mathcal{F})$. There is always a natural map $\check{H}^p(X, \mathcal{F}) \to H^p(X, \mathcal{F})$, which is an isomorphism for $p \le 1$, and for all p if X is paracompact Hausdorff [God58, Chapter II, Section 5]. Cohomology classes in $\check{H}^1(\mathcal{U}, \mathcal{F})$ are represented by cocycles (g_{ij}) with $g_{ij} + g_{jk} = g_{ik}$; for nonabelian sheaves of groups such as $\mathrm{GL}_n(\mathcal{O}_X)$ the same formula (written multiplicatively) classifies locally free sheaves of rank n (Chapter 35).

26.6 Comparison with singular cohomology

Theorem 26.6.1. *Let X be a paracompact Hausdorff, locally contractible space (for instance a manifold or a CW complex) and A an abelian group. Then $H^p(X, A_X) \cong H^p(X; A)$, the singular cohomology, naturally in X (and compatibly with cup products [Bre97, Chapter III]).*

Sketch of proof. Let $\mathcal{S}^p$ be the sheafification of the presheaf $U \mapsto C^p(U; A)$ of singular cochains. Since every point has arbitrarily small contractible neighbourhoods, the stalks of the cohomology presheaves $U \mapsto H^p(U; A)$ vanish for $p > 0$ and equal A for $p = 0$, so $0 \to A_X \to \mathcal{S}^\bullet$ is a resolution (sheafification preserves stalks and stalks are exact). The omitted verifications are that the sheaves $\mathcal{S}^p$ are soft on a paracompact space, and that $\Gamma(X, \mathcal{S}^\bullet) = C^\bullet(X; A)/C_0^\bullet(X; A)$, where $C_0^\bullet$ consists of cochains vanishing on sufficiently small simplices of some open cover, which is acyclic by the subdivision argument of Proposition 21.5.3; see [Bre97, Chapter III]. Then Theorem 26.4.5 gives $H^p(X, A_X) \cong H^p(C^\bullet(X; A)/C_0^\bullet) \cong H^p(X; A)$. □

Example 26.6.2. $H^p(\mathbb{R}^n, \mathbb{Z}) = 0$ for $p > 0$, $H^p(S^n, \mathbb{Z})$ is $\mathbb{Z}$ for $p = 0, n$, and on a closed oriented surface of genus g, $H^1(\Sigma_g, \mathbb{Z}) \cong \mathbb{Z}^{2g}$. On spaces that are not locally contractible sheaf and singular cohomology can differ: for the topologist's sine curve T of Counterexample 18.5.8, singular cohomology sees two path components, $H^0(T; \mathbb{Z}) = \mathbb{Z}^2$, while $H^0(T, \mathbb{Z}_T) = \mathbb{Z}$ since T is connected.

Example 26.6.3. Cover S^1 by two open arcs U, V with $U \cap V = W_1 \sqcup W_2$, two disjoint arcs. Let $\mathcal{L}$ be the local system of rank one with monodromy -1, obtained by gluing $\mathbb{Z}_U$ and $\mathbb{Z}_V$ by the identity over W_1 and by -1 over W_2 (Proposition 25.2.5 and Definition 25.5.1). The arcs and their intersections are homeomorphic to intervals, so the constant sheaf $\mathbb{Z}$ has no higher cohomology on them (Theorem 26.6.1), and Leray's theorem (Theorem 26.5.3) lets us compute with the cover $\{U, V\}$. In the trivialisation over V, the Čech complex is $\mathbb{Z}^2 \to \mathbb{Z}^2$, $(a, b) \mapsto (b - a, b + a)$, one coordinate for each W_i. Its kernel is 0 and its image is $\{(x, y) : x \equiv y \pmod 2\}$, so

$$H^0(S^1, \mathcal{L}) = 0, \qquad H^1(S^1, \mathcal{L}) \cong \mathbb{Z}/2.$$

For the constant sheaf the differential is $(a, b) \mapsto (b - a, b - a)$, which gives $H^0 = H^1 = \mathbb{Z}$, in accordance with Theorem 26.6.1. With coefficients in $\mathbb{Q}$ the twisted local system has $H^0 = H^1 = 0$, since the determinant 2 of the differential becomes invertible: a nontrivial local system can have vanishing rational cohomology on a space whose ordinary cohomology does not vanish.

26.7 Hypercohomology and the Leray spectral sequence

Proposition 26.7.1. *Let $\mathcal{K}^\bullet$ be a complex of sheaves with $\mathcal{K}^p = 0$ for $p < 0$.*

1. *A quasi-isomorphism $\mathcal{K}^\bullet \to \mathcal{L}^\bullet$ induces isomorphisms on hypercohomology.*
2. *There are convergent spectral sequences $E_1^{p,q} = H^q(X, \mathcal{K}^p) \Rightarrow \mathbb{H}^{p+q}(X, \mathcal{K}^\bullet)$ and $E_2^{p,q} = H^p(X, \mathcal{H}^q(\mathcal{K}^\bullet)) \Rightarrow \mathbb{H}^{p+q}(X, \mathcal{K}^\bullet)$, where $\mathcal{H}^q$ are the cohomology sheaves.*
3. *If every $\mathcal{K}^p$ is Γ-acyclic, $\mathbb{H}^p(X, \mathcal{K}^\bullet) = H^p(\Gamma(X, \mathcal{K}^\bullet))$. If $\mathcal{F} \to \mathcal{K}^\bullet$ is a resolution, then $\mathbb{H}^p(X, \mathcal{K}^\bullet) = H^p(X, \mathcal{F})$.*

Proof. (1) Quasi-isomorphisms are isomorphisms in the derived category, and $R\Gamma$ is a functor on it. (2) is Proposition 17.4.8. (3) The first statement is Lemma 17.4.6, and the second follows from (1) applied to $\mathcal{F} \to \mathcal{K}^\bullet$, with $\mathcal{F}$ in degree 0. □

Remark 26.7.2. On a complex manifold X the holomorphic de Rham complex $\Omega_X^\bullet$ is a resolution of $\mathbb{C}_X$ (the holomorphic Poincaré lemma), so $H^k(X;\mathbb{C}) \cong \mathbb{H}^k(X, \Omega_X^\bullet)$, and the first spectral sequence of Proposition 26.7.1 becomes the *Hodge-to-de Rham* (Frölicher) spectral sequence $E_1^{p,q} = H^q(X, \Omega_X^p) \Rightarrow H^{p+q}(X;\mathbb{C})$. Its degeneration for compact Kähler manifolds is a form of the Hodge decomposition (Chapter 48).

Theorem 26.7.3 (Leray spectral sequence)**.** *Let $f : X \to Y$ be continuous and $\mathcal{F}$ a sheaf of abelian groups on X. Then $R^q f_*\mathcal{F}$ is the sheafification of the presheaf $V \mapsto H^q(f^{-1}V, \mathcal{F})$, and there is a convergent spectral sequence $E_2^{p,q} = H^p(Y, R^q f_*\mathcal{F}) \Rightarrow H^{p+q}(X, \mathcal{F})$.*

Proof. Let $\mathcal{F} \to I^\bullet$ be an injective resolution. Then $R^q f_*\mathcal{F} = \mathcal{H}^q(f_* I^\bullet)$, the sheafification of the presheaf of cohomology groups $V \mapsto H^q(I^\bullet(f^{-1}V))$, and $H^q(I^\bullet(f^{-1}V)) = H^q(f^{-1}V, \mathcal{F})$ because $I^\bullet|_{f^{-1}V}$ is an injective resolution (Lemma 26.2.1). Since $\Gamma(X, -) = \Gamma(Y, -) \circ f_*$ and f_* preserves injectives, which are $\Gamma(Y, -)$-acyclic, the Grothendieck spectral sequence (Theorem 16.6.3) applies. □

Example 26.7.4. If f is a closed embedding, f_* is exact (compute stalks as in Proposition 25.4.4), so $H^p(Y, f_*\mathcal{F}) \cong H^p(X, \mathcal{F})$. For a locally trivial fibre bundle $f : E \to B$ with fibre F over a locally contractible paracompact base, $R^q f_*\mathbb{Z}_E$ is the local system with stalks $H^q(F;\mathbb{Z})$, and the Leray spectral sequence becomes the *Serre spectral sequence* $E_2^{p,q} = H^p(B, \mathcal{H}^q(F)) \Rightarrow H^{p+q}(E;\mathbb{Z})$ with local coefficients [Bre97].

26.8 Cohomology with compact supports

Definition 26.8.1. Let X be locally compact Hausdorff. The *support* of a section $s \in \mathcal{F}(X)$ is the closed set $\{x : s_x \neq 0\}$. Let $\Gamma_c(X, \mathcal{F})$ be the group of sections with compact support, a left exact functor, and $H_c^i(X, \mathcal{F}) = R^i\Gamma_c(X, \mathcal{F})$.

Remark 26.8.2. Flasque sheaves are Γ_c-acyclic, and on locally compact Hausdorff spaces that are countable at infinity, so are soft sheaves; so H_c^* can be computed by fine resolutions. For a manifold M and an abelian group A, $H_c^i(M, A_M)$ agrees with the compactly supported singular cohomology of Definition 23.5.2, and Poincaré duality generalises to *Verdier duality* $R\Gamma_c(X, \mathcal{F})^\vee \cong R\operatorname{Hom}(\mathcal{F}, \omega_X)$ in the derived category, with $\omega_X = or_X[n]$ for an n-manifold [KS90, Chapter III], [Ive86].

26.9 Exercises

Exercise 26.9.1. Compute $\check{H}^\bullet(\mathcal{U}, \mathbb{Z}_{S^1})$ for the cover of S^1 by two open arcs whose intersection has two components, and check with Theorems 26.5.3 and 26.6.1 that $H^1(S^1, \mathbb{Z}) \cong \mathbb{Z}$.

Solution. With $I = \{0, 1\}$, $\check{C}^0 = \mathbb{Z}_{S^1}(U_0) \oplus \mathbb{Z}_{S^1}(U_1) = \mathbb{Z}^2$, $\check{C}^1 = \mathbb{Z}_{S^1}(U_0 \cap U_1) = \mathbb{Z}^2$ and $d(a, b) = (b - a, b - a)$. So $\check{H}^0 = \mathbb{Z}$ and $\check{H}^1 = \mathbb{Z}^2/\{(c, c)\} \cong \mathbb{Z}$. The arcs and the components of their intersection are contractible, hence have no higher cohomology with constant coefficients, so Leray's theorem applies. □

Exercise 26.9.2. Show that skyscraper sheaves are flasque, and that $H^i(X, x_*A) = 0$ for $i > 0$.

Solution. Restriction maps are identities or maps to 0. Flasque sheaves are acyclic (Proposition 26.3.3). □

Exercise 26.9.3. Let X be an irreducible space (every nonempty open subset is dense). Show that every constant sheaf on X is flasque, and deduce $H^i(X, A_X) = 0$ for $i > 0$. (This applies to algebraic varieties with the Zariski topology, and shows that sheaf cohomology of constant sheaves in that topology does not see the classical topology.)

Solution. Nonempty open subsets of an irreducible space are connected (two disjoint nonempty open subsets would contradict density), so locally constant functions on them are constant, and $A_X(U) = A$ for $U \neq \emptyset$, with identity restriction maps. □

Exercise 26.9.4. For open $U, V \subseteq X$ and a sheaf $\mathcal{F}$, construct a long exact Mayer–Vietoris sequence $\cdots \to H^i(U \cup V, \mathcal{F}) \to H^i(U, \mathcal{F}) \oplus H^i(V, \mathcal{F}) \to H^i(U \cap V, \mathcal{F}) \to H^{i+1}(U \cup V, \mathcal{F}) \to \cdots$. (Hint: for flasque I, $0 \to I(U \cup V) \to I(U) \oplus I(V) \to I(U \cap V) \to 0$ is exact.)

Analysis

Chapter 27

Real Analysis

27.1 Introduction

This chapter develops calculus in one and several real variables with complete proofs, starting slowly from limits of sequences and of functions: the sequential characterisation of limits, continuous functions and the theorems of Bolzano, Weierstrass and Heine–Cantor, the mean value theorems, de l'Hôpital's rule, Taylor's formula and convexity; then series and power series, the exponential and trigonometric functions (including a definition of π), the Riemann integral, uniform convergence of sequences of functions (with a continuous nowhere differentiable function), derivatives of maps between Euclidean spaces, curves, their length and the line integrals of the first and second kind, the inverse and implicit function theorems, extrema in several variables with Lagrange multipliers and the Karush–Kuhn–Tucker conditions of optimisation, ordinary differential equations, and the approximation and compactness theorems of Stone–Weierstrass and Arzelà–Ascoli. The topological background (metric spaces, compactness, completeness, uniform convergence, the Banach fixed point theorem) is in Chapter 18. References: [Rud76], [Die60], [Spi65], [Lan93] and [Har02].

Prerequisites. Chapter 18 (General Topology), Chapter 4 (Number Systems) and Chapter 11 (Linear Algebra); Theorem 27.7.3 also uses Chapter 19 (Homotopy and Covering Spaces).

On the way to the Hodge conjecture. Needed: limits, continuity, series, differentiation, the exponential function, the Riemann integral, sequences of functions, derivatives in several variables and the inverse and implicit function theorems; the length of curves and line integrals (Section 27.11) are used for paths and periods; ordinary differential equations (Section 27.14) give the flows of vector fields. Extrema and Lagrange multipliers (Section 27.13) and the Stone–Weierstrass and Arzelà–Ascoli theorems (Section 27.15) can be postponed.

Throughout, $\mathbb{K}$ is $\mathbb{R}$ or $\mathbb{C}$, and $\mathbb{R}^n$ and $\mathbb{C}^n$ carry the Euclidean norm unless otherwise stated.

27.2 Limits of sequences

We recall that a real sequence $(a_n)_{n\in\mathbb{N}}$ *converges* to $a \in \mathbb{R}$ if for every $\varepsilon > 0$ there is N with $|a_n - a| < \varepsilon$ for all $n \geq N$ (Definition 4.7.5). This is convergence in the metric space $\mathbb{R}$ (Chapter 18). In this section we develop the theory of limits of sequences directly from this definition.

Definition 27.2.1. Let (a_n) be a real sequence.

1. If (a_n) converges to a we write $a_n \to a$ or $\lim_n a_n = a$, and call a the *limit*.

2. (a_n) *diverges to* $+\infty$, written $a_n \to +\infty$, if for every $M \in \mathbb{R}$ there is N with $a_n > M$ for all $n \geq N$; similarly $a_n \to -\infty$ if for every M eventually $a_n < M$.

3. (a_n) is *regular* if it converges or diverges to $\pm\infty$, and *oscillating* otherwise.

4. (a_n) is *bounded* if there is C with $|a_n| \leq C$ for all n; *bounded above* or *below* are defined similarly.

5. (a_n) is *increasing* if $a_n \leq a_{n+1}$ for all n, *strictly increasing* if $a_n < a_{n+1}$, and similarly *decreasing*; it is *monotone* if it is increasing or decreasing.

6. A *subsequence* of (a_n) is a sequence $(a_{n_k})_{k\in\mathbb{N}}$ with $n_0 < n_1 < n_2 < \cdots$.

A property holds *eventually*, or *for large* n, if there is N such that it holds for all $n \geq N$.

Proposition 27.2.2. *Let (a_n) be a real sequence.*

1. *A sequence has at most one limit.*

2. *A convergent sequence is bounded.*

3. *(Permanence of sign) If $a_n \to a$ and $a > 0$, then $a_n > a/2 > 0$ for large n.*

4. *Changing, adding or removing finitely many terms does not affect convergence or the limit.*

5. *If $a_n \to a$, every subsequence converges to a; the same holds for divergence to $\pm\infty$.*

Proof. (1) Suppose $a_n \to a$ and $a_n \to b$ with $a \neq b$, and let $\varepsilon = |a-b|/2$. For n larger than both thresholds, $|a-b| \leq |a-a_n| + |a_n - b| < 2\varepsilon = |a-b|$, a contradiction. (2) Take $\varepsilon = 1$: for $n \geq N$, $|a_n| \leq |a_n - a| + |a| < |a| + 1$, so $|a_n| \leq \max(|a_0|, \ldots, |a_{N-1}|, |a| + 1)$ for all n. (3) Take $\varepsilon = a/2$: then $a_n > a - a/2 = a/2$ for large n. (4) The definitions only involve the terms with $n \geq N$, and N may be enlarged. (5) By induction $n_k \geq k$, so $k \geq N$ implies $n_k \geq N$. □

Lemma 27.2.3 (Bernoulli's inequality)**.** *For $h \geq -1$ and $n \in \mathbb{N}$, $(1+h)^n \geq 1 + nh$.*

Proof. For $n = 0$ both sides are 1. If $(1+h)^n \geq 1 + nh$, then, as $1 + h \geq 0$, $(1+h)^{n+1} \geq (1+nh)(1+h) = 1 + (n+1)h + nh^2 \geq 1 + (n+1)h$. □

Proposition 27.2.4 (Algebra of limits)**.** *Let $a_n \to a$ and $b_n \to b$ be real sequences and $c \in \mathbb{R}$. Then $a_n + b_n \to a + b$, $ca_n \to ca$, $a_n b_n \to ab$ and $|a_n| \to |a|$. If $b \neq 0$, then $b_n \neq 0$ for large n and $a_n/b_n \to a/b$.*

Proof. Given $\varepsilon > 0$, for large n we have $|a_n - a| < \varepsilon/2$ and $|b_n - b| < \varepsilon/2$, so $|(a_n + b_n) - (a+b)| < \varepsilon$. The reverse triangle inequality $||a_n| - |a|| \leq |a_n - a|$ gives $|a_n| \to |a|$, and $|ca_n - ca| = |c|\,|a_n - a|$ gives $ca_n \to ca$. For the product, let C bound $|a_n|$ (Proposition 27.2.2(2)); then

$$|a_n b_n - ab| \leq |a_n||b_n - b| + |b||a_n - a| \leq C|b_n - b| + |b||a_n - a|,$$

which is less than ε for large n. For the quotient it suffices to show $1/b_n \to 1/b$. As $|b_n| \to |b| > 0$, permanence of sign gives $|b_n| > |b|/2$ for large n, and then $|1/b_n - 1/b| = |b - b_n|/(|b_n||b|) \leq 2|b_n - b|/|b|^2$, which tends to 0. □

Proposition 27.2.5 (Comparison and squeeze)**.** *Let (a_n), (b_n), (c_n) be real sequences.*

1. *If $a_n \leq b_n$ for large n, $a_n \to a$ and $b_n \to b$, then $a \leq b$.*

2. *(Squeeze theorem) If $a_n \leq c_n \leq b_n$ for large n and $a_n \to L$, $b_n \to L$, then $c_n \to L$.*

3. *If $a_n \le b_n$ for large n and $a_n \to +\infty$, then $b_n \to +\infty$.*

4. *If $|a_n| \le b_n$ for large n and $b_n \to 0$, then $a_n \to 0$. In particular, if (a_n) is bounded and $b_n \to 0$, then $a_n b_n \to 0$.*

Proof. (1) If $a > b$, then $a_n - b_n \to a - b > 0$ by Proposition 27.2.4, so $a_n - b_n > 0$ for large n by permanence of sign, a contradiction. (2) Given $\varepsilon > 0$, for large n we have $L - \varepsilon < a_n \le c_n \le b_n < L + \varepsilon$. (3) Eventually $b_n \ge a_n > M$. (4) Apply (2) to $-b_n \le a_n \le b_n$; for the last statement, $|a_n b_n| \le C|b_n|$. □

Counterexample 27.2.6. Strict inequalities do not pass to the limit: $1/(n+1) > 0$ for all n, but the limit is 0. The convergence $|a_n| \to |a|$ does not imply $a_n \to a$ unless $a = 0$: the sequence $a_n = (-1)^n$ oscillates although $|a_n| \to 1$.

Proposition 27.2.7 (Infinite limits)**.** *Let $a_n \to +\infty$.*

1. *If (b_n) is bounded below, then $a_n + b_n \to +\infty$.*

2. *If $b_n \ge c$ for large n, for some $c > 0$, then $a_n b_n \to +\infty$.*

3. *$a_n > 0$ for large n, and $1/a_n \to 0$. Conversely, if $b_n > 0$ and $b_n \to 0$, then $1/b_n \to +\infty$.*

Proof. (1) If $b_n \ge -C$, then for any M, eventually $a_n > M + C$, so $a_n + b_n > M$. (2) Eventually $a_n > M/c$ with $M > 0$, so $a_n b_n > M$. (3) Eventually $a_n > 1/\varepsilon > 0$, so $0 < 1/a_n < \varepsilon$. Conversely, eventually $0 < b_n < 1/M$ for $M > 0$, so $1/b_n > M$. □

Counterexample 27.2.8 (Indeterminate forms)**.** If $a_n \to +\infty$ and $b_n \to -\infty$, the limits alone do not determine the behaviour of $a_n + b_n$: with $a_n = n$, the choices $b_n = -n + c$, $b_n = -n/2$, $b_n = -2n$ and $b_n = -n + (-1)^n$ give the limit c, the limit $+\infty$, the limit $-\infty$, and an oscillating sequence. Similarly, if $a_n \to 0$ and $b_n \to +\infty$, then with $a_n = 1/(n+1)$ the choices $b_n = c(n+1)$, $(n+1)^2$ and $(-1)^n(n+1)$ show that $a_n b_n$ can converge to any c, diverge, or oscillate. The same happens for the forms ∞/∞ and $0/0$.

Proposition 27.2.9 (Fundamental limits)**.** 1. *For $q \in \mathbb{R}$: $q^n \to 0$ if $|q| < 1$, $q^n \to 1$ if $q = 1$, $q^n \to +\infty$ if $q > 1$, and (q^n) oscillates if $q \le -1$.*

2. *For $a > 0$, $a^{1/n} \to 1$, and $n^{1/n} \to 1$.*

3. *For $k \in \mathbb{N}$ and $a > 1$, $n^k/a^n \to 0$: exponentials beat powers.*

4. *For every $a \in \mathbb{R}$, $a^n/n! \to 0$, and $n!/n^n \to 0$.*

Proof. (1) If $q > 1$, write $q = 1 + h$ with $h > 0$; by Lemma 27.2.3, $q^n \ge 1 + nh \to +\infty$. If $0 < |q| < 1$, then $|q|^{-n} \to +\infty$, so $|q^n| \to 0$ by Proposition 27.2.7(3), and $q^n \to 0$ by Proposition 27.2.5(4). If $q = -1$ the terms alternate between ± 1; if $q < -1$, $|q^n| \to +\infty$ and the signs alternate, so the sequence is unbounded above and below and has no limit. (2) Let $a \ge 1$ and $a^{1/n} = 1 + h_n$ with $h_n \ge 0$ (the n-th root exists by Proposition 4.7.4). By Bernoulli, $a \ge 1 + nh_n$, so $0 \le h_n \le (a-1)/n \to 0$. For $a < 1$ apply this to $1/a$ and use Proposition 27.2.4. For $n^{1/n} = 1 + h_n$ with $n \ge 2$, the binomial formula gives $n \ge \binom{n}{2} h_n^2$, so $0 \le h_n \le \sqrt{2/(n-1)} \to 0$. (3) Write $a = 1 + h$. For $n \ge 2k + 2$ the binomial formula gives $a^n \ge \binom{n}{k+1} h^{k+1} \ge \frac{(n/2)^{k+1}}{(k+1)!} h^{k+1}$, since each of the $k+1$ factors $n, n-1, \dots, n-k$ is at least $n/2$. Hence $0 \le n^k/a^n \le 2^{k+1}(k+1)!/(h^{k+1} n) \to 0$. (4) Choose an integer $N > 2|a|$. For $n \ge N$, $|a|^n/n! \le \frac{|a|^N}{N!} 2^{N-n}$, which tends to 0 by (1). Finally $n!/n^n = \frac{1}{n} \cdot \frac{2}{n} \cdots \frac{n}{n} \le \frac{1}{n}$. □

Proposition 27.2.10. *Every monotone sequence is regular. An increasing sequence converges to its supremum if it is bounded above, and diverges to $+\infty$ otherwise; a decreasing sequence converges to its infimum if it is bounded below, and diverges to $-\infty$ otherwise.*

Proof. Let (a_n) be increasing. If it is bounded above, let $s = \sup_n a_n$ (Definition 4.7.1). For $\varepsilon > 0$, $s - \varepsilon$ is not an upper bound, so $a_N > s - \varepsilon$ for some N, and then $s - \varepsilon < a_N \le a_n \le s$ for $n \ge N$. If it is not bounded above, for every M some $a_N > M$, and then $a_n \ge a_N > M$ for $n \ge N$. The decreasing case follows by passing to $(-a_n)$. □

Lemma 27.2.11. *Every real sequence has a monotone subsequence.*

Proof. Call n a *peak* if $a_n \ge a_m$ for all $m > n$. If there are infinitely many peaks $n_0 < n_1 < \cdots$, then $a_{n_0} \ge a_{n_1} \ge \cdots$ is a decreasing subsequence. Otherwise let n_0 be larger than all peaks. As n_0 is not a peak, there is $n_1 > n_0$ with $a_{n_1} > a_{n_0}$; as n_1 is not a peak, there is $n_2 > n_1$ with $a_{n_2} > a_{n_1}$; continuing (by recursion), we obtain a strictly increasing subsequence. □

Theorem 27.2.12 (Bolzano–Weierstrass)**.** *Every bounded real sequence has a convergent subsequence. Every real sequence has a regular subsequence: a sequence that is unbounded above has a subsequence diverging to $+\infty$.*

Proof. By Lemma 27.2.11 there is a monotone subsequence, which is regular by Proposition 27.2.10, and convergent if the sequence is bounded. If (a_n) is unbounded above, choose recursively $n_{k+1} > n_k$ with $a_{n_{k+1}} > k + 1$, which is possible because only finitely many terms have index $\le n_k$. □

Theorem 27.2.13 (Cauchy criterion)**.** *A real sequence converges if and only if it is a Cauchy sequence.*

Proof. If $a_n \to a$, then $|a_n - a_m| \le |a_n - a| + |a - a_m| < \varepsilon$ when both are within $\varepsilon/2$ of a. Conversely, let (a_n) be Cauchy. Taking $\varepsilon = 1$ shows that (a_n) is bounded, so by Theorem 27.2.12 a subsequence converges to some a. Given $\varepsilon > 0$, choose N with $|a_n - a_m| < \varepsilon/2$ for $m, n \ge N$, and k with $n_k \ge N$ and $|a_{n_k} - a| < \varepsilon/2$. Then $|a_n - a| \le |a_n - a_{n_k}| + |a_{n_k} - a| < \varepsilon$ for $n \ge N$. (This is a second proof of Proposition 4.7.6 for $\mathbb{R}$.) □

Counterexample 27.2.14. It is not enough that consecutive terms get close. The partial sums $H_n = \sum_{k=1}^{n} 1/k$ of the harmonic series satisfy $H_{n+1} - H_n = 1/(n+1) \to 0$, but $H_{2n} - H_n = \sum_{k=n+1}^{2n} 1/k \ge n \cdot \frac{1}{2n} = \frac{1}{2}$, so (H_n) is not Cauchy; being increasing, it diverges to $+\infty$. Likewise $\sqrt{n+1} - \sqrt{n} = 1/(\sqrt{n+1} + \sqrt{n}) \to 0$ while $\sqrt{n} \to +\infty$.

Proposition 27.2.15 (Subsequence criterion)**.**

1. *$a_n \to a$ if and only if every subsequence of (a_n) has a further subsequence converging to a.*
2. *A bounded sequence all of whose convergent subsequences have the same limit a converges to a.*

Proof. (1) One direction is Proposition 27.2.2(5). Conversely, if $a_n \not\to a$, there is $\varepsilon > 0$ such that $|a_n - a| \ge \varepsilon$ for infinitely many n; these terms form a subsequence none of whose subsequences converges to a. (2) By Theorem 27.2.12, every subsequence is bounded and has a convergent subsequence, whose limit is a by hypothesis; apply (1). □

Proposition 27.2.16 (Stolz–Cesàro)**.** *Let (b_n) be strictly increasing with $b_n \to +\infty$, and let (a_n) be a real sequence with $\frac{a_{n+1}-a_n}{b_{n+1}-b_n} \to L \in \mathbb{R}$. Then $a_n/b_n \to L$. In particular (Cesàro), if $a_n \to L$, then the averages $\frac{1}{n}(a_1 + \cdots + a_n) \to L$.*

Proof. Let $\varepsilon > 0$ and choose N such that $b_N > 0$ and $|(a_{k+1} - a_k) - L(b_{k+1} - b_k)| \leq \varepsilon(b_{k+1} - b_k)$ for $k \geq N$. Summing over $N \leq k < n$ gives $|a_n - a_N - L(b_n - b_N)| \leq \varepsilon(b_n - b_N) \leq \varepsilon b_n$. Dividing by $b_n > 0$,

$$\left|\frac{a_n}{b_n} - L\right| \leq \varepsilon + \frac{|a_N - Lb_N|}{b_n},$$

and the last term is less than ε for large n, as $b_n \to +\infty$. For Cesàro, apply this to $a'_n = a_1 + \cdots + a_n$ and $b_n = n$. □

Counterexample 27.2.17. The converse of Cesàro's theorem fails: $a_n = (-1)^n$ does not converge, but its averages tend to 0, since the partial sums are 0 or -1.

27.3 Limits of functions

To treat finite and infinite limits at once we use the *extended real line* $\bar{\mathbb{R}} = \mathbb{R} \cup \{-\infty, +\infty\}$, ordered so that $-\infty < x < +\infty$ for $x \in \mathbb{R}$.

Definition 27.3.1. For $a \in \bar{\mathbb{R}}$ and $\delta > 0$, the *basic neighbourhood* $U_\delta(a)$ is $(a - \delta, a + \delta)$ if $a \in \mathbb{R}$, $(1/\delta, +\infty)$ if $a = +\infty$, and $(-\infty, -1/\delta)$ if $a = -\infty$. Let $D \subseteq \mathbb{R}$. A point $a \in \bar{\mathbb{R}}$ is an *accumulation point* of D if every $U_\delta(a)$ contains a point of $D \setminus \{a\}$. A point of D that is not an accumulation point is *isolated*.

A sequence (x_n) tends to $a \in \bar{\mathbb{R}}$ if and only if for every $\delta > 0$, eventually $x_n \in U_\delta(a)$: for $a \in \mathbb{R}$ this is convergence, and for $a = \pm\infty$ divergence to $\pm\infty$. Every $a \in \bar{\mathbb{R}}$ that is an accumulation point of D is the limit of a sequence in $D \setminus \{a\}$: choose $x_n \in U_{1/(n+1)}(a) \cap D \setminus \{a\}$.

Definition 27.3.2. Let $f : D \to \mathbb{R}$, let $a \in \bar{\mathbb{R}}$ be an accumulation point of D, and $L \in \bar{\mathbb{R}}$. We write $\lim_{x \to a} f(x) = L$, or $f(x) \to L$ as $x \to a$, if for every $\varepsilon > 0$ there is $\delta > 0$ such that $f(x) \in U_\varepsilon(L)$ for all $x \in D \cap U_\delta(a)$ with $x \neq a$. For $a, L \in \mathbb{R}$ this reads: for every $\varepsilon > 0$ there is $\delta > 0$ with $|f(x) - L| < \varepsilon$ whenever $x \in D$ and $0 < |x - a| < \delta$. The *right limit* $\lim_{x \to a^+} f(x)$ is the limit of the restriction of f to $D \cap (a, +\infty)$, when a is an accumulation point of that set, and the *left limit* $\lim_{x \to a^-} f(x)$ is defined similarly. The same definitions apply to $\mathbb{C}$- or $\mathbb{R}^m$-valued functions and finite limits, with $|\cdot|$ the modulus or the Euclidean norm.

The value of f at a, if $a \in D$, plays no role in the definition.

Proposition 27.3.3. *Let $f : D \to \mathbb{R}$ and let $a \in \bar{\mathbb{R}}$ be an accumulation point of D.*

1. *The limit of f at a, if it exists, is unique.*
2. *If $\lim_{x \to a} f(x) = L \in \mathbb{R}$, then f is bounded on $D \cap U_\delta(a) \setminus \{a\}$ for some $\delta > 0$; if $L > 0$, then $f(x) > L/2$ for $x \in D \cap U_\delta(a) \setminus \{a\}$ for some $\delta > 0$.*
3. *If $a \in \mathbb{R}$ is an accumulation point of both $D \cap (a, +\infty)$ and $D \cap (-\infty, a)$, then $\lim_{x \to a} f(x) = L$ if and only if both one-sided limits exist and equal L.*

Proof. (1) If $L \neq L'$ are both limits, choose ε with $U_\varepsilon(L) \cap U_\varepsilon(L') = \emptyset$, and δ working for both; since a is an accumulation point, some $x \in D \cap U_\delta(a) \setminus \{a\}$ exists, and $f(x)$ lies in both neighbourhoods. (2) Take $\varepsilon = 1$, respectively $\varepsilon = L/2$. (3) If both one-sided limits equal L, take the smaller of the two δ; the converse is clear. □

Theorem 27.3.4 (Sequential characterisation of limits)**.** *Let $f : D \to \mathbb{R}$, let $a \in \bar{\mathbb{R}}$ be an accumulation point of D, and $L \in \bar{\mathbb{R}}$. The following are equivalent:*

1. $\lim_{x \to a} f(x) = L$;

2. *for every sequence (x_n) in $D \setminus \{a\}$ with $x_n \to a$, we have $f(x_n) \to L$.*

Proof. (1) $\Rightarrow$ (2). Let $\varepsilon > 0$ and choose δ as in Definition 27.3.2. Eventually $x_n \in U_\delta(a)$, and $x_n \in D \setminus \{a\}$, so eventually $f(x_n) \in U_\varepsilon(L)$.

(2) $\Rightarrow$ (1). Suppose (1) fails. Then there is $\varepsilon > 0$ such that for every $\delta > 0$ some $x \in D \cap U_\delta(a) \setminus \{a\}$ has $f(x) \notin U_\varepsilon(L)$. Choosing such a point x_n for $\delta = 1/(n+1)$, for each n (this uses the axiom of countable choice), we obtain a sequence in $D \setminus \{a\}$ with $x_n \to a$ and $f(x_n) \notin U_\varepsilon(L)$ for all n, so $f(x_n) \not\to L$, contradicting (2). □

Theorem 27.3.4, sometimes called the *bridge theorem*, transfers every result about limits of sequences to limits of functions, and it is the standard way to show that a limit does *not* exist: exhibit two sequences tending to a along which f has different limits.

Corollary 27.3.5 (Rules for limits of functions)**.** *Let $f, g, h \colon D \to \mathbb{R}$ and let $a \in \bar{\mathbb{R}}$ be an accumulation point of D.*

1. *If $f(x) \to L$ and $g(x) \to M$ with $L, M \in \mathbb{R}$, then $f+g \to L+M$, $fg \to LM$, and, if $M \neq 0$, $f/g \to L/M$ (where f/g is defined near a).*
2. *If $f \leq g$ near a and $f \to L$, $g \to M$, then $L \leq M$.*
3. *(Squeeze) If $f \leq h \leq g$ near a and $f(x) \to L$, $g(x) \to L$, then $h(x) \to L$.*
4. *The rules for infinite limits of Proposition 27.2.7 hold for functions.*

Proof. Apply Theorem 27.3.4 and Propositions 27.2.4, 27.2.5 and 27.2.7 to $f(x_n)$, $g(x_n)$, $h(x_n)$ for sequences $x_n \to a$ in $D \setminus \{a\}$. For the quotient, $g(x) \neq 0$ near a by Proposition 27.3.3(2) applied to $|g|$. □

Proposition 27.3.6 (Limits of composite functions)**.** *Let $f \colon D \to \mathbb{R}$ and $g \colon E \to \mathbb{R}$ with $f(D) \subseteq E$. Suppose $\lim_{x\to a} f(x) = b$ and $\lim_{y\to b} g(y) = L$, and that one of the following holds:*

1. *$f(x) \neq b$ for all $x \in D \setminus \{a\}$ near a;*
2. *$b \in E$ and $g(b) = L$.*

Then $\lim_{x\to a} g(f(x)) = L$.

Proof. Let $x_n \to a$ in $D \setminus \{a\}$. Then $f(x_n) \to b$ by Theorem 27.3.4. In case (1), eventually $f(x_n) \in E \setminus \{b\}$, so $g(f(x_n)) \to L$ by the same theorem. In case (2), given $\varepsilon > 0$ choose η with $g(y) \in U_\varepsilon(L)$ for $y \in E \cap U_\eta(b)$, including $y = b$; eventually $f(x_n) \in U_\eta(b)$, so $g(f(x_n)) \in U_\varepsilon(L)$. Apply the theorem again. □

Counterexample 27.3.7. Neither hypothesis can be dropped. Let $f(x) = 0$ for all x, and $g(y) = 0$ for $y \neq 0$, $g(0) = 1$. Then $\lim_{x\to 0} f(x) = 0$ and $\lim_{y\to 0} g(y) = 0$, but $g(f(x)) = 1$ for all x.

Proposition 27.3.8 (Cauchy criterion for functions)**.** *Let $f \colon D \to \mathbb{R}$ and let $a \in \bar{\mathbb{R}}$ be an accumulation point of D. Then $\lim_{x\to a} f(x)$ exists in $\mathbb{R}$ if and only if for every $\varepsilon > 0$ there is $\delta > 0$ with $|f(x) - f(y)| < \varepsilon$ for all $x, y \in D \cap U_\delta(a) \setminus \{a\}$.*

Proof. If $f(x) \to L$, take δ for $\varepsilon/2$ and use the triangle inequality. Conversely, for every sequence $x_n \to a$ in $D \setminus \{a\}$, the sequence $(f(x_n))$ is Cauchy, hence converges (Theorem 27.2.13). If $x_n \to a$ and $y_n \to a$ are two such sequences, the interleaved sequence $x_0, y_0, x_1, y_1, \ldots$ also tends to a, so $(f(x_n))$ and $(f(y_n))$ have the same limit, being subsequences of a convergent sequence. So all these limits equal a common L, and $f(x) \to L$ by Theorem 27.3.4. □

Proposition 27.3.9 (Monotone functions)**.** *Let $f : (a, b) \to \mathbb{R}$ be increasing, with $-\infty \le a < b \le +\infty$. For every $c \in (a, b)$ the one-sided limits exist and*

$$\lim_{x \to c^-} f(x) = \sup_{a<x<c} f(x) \le f(c) \le \inf_{c<x<b} f(x) = \lim_{x \to c^+} f(x),$$

and $\lim_{x\to b^-} f(x) = \sup f \in \mathbb{R} \cup \{+\infty\}$, $\lim_{x\to a^+} f(x) = \inf f \in \mathbb{R} \cup \{-\infty\}$. The analogous statements hold for decreasing functions.

Proof. The set $\{f(x) : a < x < c\}$ is bounded above by $f(c)$; let s be its supremum, so $s \le f(c)$. Given $\varepsilon > 0$ there is $x_0 < c$ with $f(x_0) > s - \varepsilon$, and for $x_0 < x < c$, $s - \varepsilon < f(x_0) \le f(x) \le s$. So $\lim_{x\to c^-} f(x) = s$. The other statements are proved in the same way (for $b = +\infty$ or an unbounded supremum, use neighbourhoods of $+\infty$), and the decreasing case follows by passing to $-f$. □

Counterexample 27.3.10.

1. The sign function $\operatorname{sgn}(x) = x/|x|$ on $\mathbb{R} \setminus \{0\}$ has one-sided limits ± 1 at 0, and no limit there.
2. $1/x$ has no limit at 0: its one-sided limits are $+\infty$ and $-\infty$.
3. The *Dirichlet function* $\mathbf{1}_{\mathbb{Q}}$, equal to 1 on $\mathbb{Q}$ and 0 on $\mathbb{R} \setminus \mathbb{Q}$, has no limit at any $a \in \mathbb{R}$. Both $\mathbb{Q}$ and $\mathbb{R} \setminus \mathbb{Q}$ are dense in $\mathbb{R}$: $\mathbb{Q}$ by Proposition 4.7.3, and $\mathbb{R} \setminus \mathbb{Q}$ because $q\sqrt{2}$ is irrational for rational $q \neq 0$ (Proposition 4.6.4) and $x/\sqrt{2} < q < y/\sqrt{2}$ is possible for $x < y$. So there are rational $x_n \to a$ and irrational $y_n \to a$, all $\neq a$, and $\mathbf{1}_{\mathbb{Q}}(x_n) \to 1$, $\mathbf{1}_{\mathbb{Q}}(y_n) \to 0$.

27.4 Continuous functions of a real variable

Definition 27.4.1. Let $D \subseteq \mathbb{R}$ and $f : D \to \mathbb{R}$. Then f is *continuous at $a \in D$* if for every $\varepsilon > 0$ there is $\delta > 0$ with $|f(x) - f(a)| < \varepsilon$ for all $x \in D$ with $|x - a| < \delta$, and *continuous* if it is continuous at every point of D.

This is continuity for the metric of $\mathbb{R}$ restricted to D (Proposition 18.3.5). If $a \in D$ is an accumulation point of D, then f is continuous at a if and only if $\lim_{x\to a} f(x) = f(a)$; if a is isolated, every f is continuous at a.

Proposition 27.4.2. *Let $f, g : D \to \mathbb{R}$ and $a \in D$.*

1. *f is continuous at a if and only if $f(x_n) \to f(a)$ for every sequence (x_n) in D with $x_n \to a$.*
2. *If f and g are continuous at a, so are $f + g$, fg, $|f|$, $\max(f, g)$, $\min(f, g)$, and f/g if $g(a) \neq 0$.*
3. *If f is continuous at a and $h : E \to \mathbb{R}$, with $f(D) \subseteq E$, is continuous at $f(a)$, then $h \circ f$ is continuous at a.*
4. *Polynomials are continuous on $\mathbb{R}$, and rational functions are continuous where the denominator does not vanish.*

Proof. (1) The proof of Theorem 27.3.4 applies verbatim, now allowing $x_n = a$. (2) follows from (1) and Proposition 27.2.4, since $\max(f, g) = \frac{1}{2}(f+g+|f-g|)$ and $\min(f, g) = \frac{1}{2}(f+g-|f-g|)$. (3) If $x_n \to a$, then $f(x_n) \to f(a)$ and so $h(f(x_n)) \to h(f(a))$. (4) Constants and the identity are continuous; apply (2). □

Definition 27.4.3. Let f be defined on an open interval containing a, and discontinuous at a. The discontinuity is *removable* if $\lim_{x\to a} f(x)$ exists in $\mathbb{R}$ (and differs from $f(a)$); it is a *jump* if both one-sided limits exist in $\mathbb{R}$ and differ; otherwise it is *essential*.

Example 27.4.4. The function equal to 1 for $x \neq 0$ and 0 at 0 has a removable discontinuity at 0. The function equal to $\operatorname{sgn}(x)$ for $x \neq 0$ and 0 at 0 has a jump. The function equal to $1/x$ for $x \neq 0$ and 0 at 0 has an essential discontinuity, and the Dirichlet function $\mathbf{1}_{\mathbb{Q}}$ has an essential discontinuity at every point (Counterexample 27.3.10).

Theorem 27.4.5. *Let $f : I \to \mathbb{R}$ be monotone on an interval I. Then every discontinuity of f at an interior point of I is a jump, and the set of points of discontinuity of f is countable.*

Proof. We may assume f increasing. At an interior point c the one-sided limits $f(c^-) \leq f(c) \leq f(c^+)$ exist by Proposition 27.3.9, and f is continuous at c if and only if $f(c^-) = f(c^+)$. So every interior discontinuity is a jump, with nonempty open interval $J_c = (f(c^-), f(c^+))$. If $c < c'$ are interior discontinuity points and $c < x < c'$, then $f(c^+) \leq f(x) \leq f(c'^-)$, so $J_c \cap J_{c'} = \emptyset$. The set $\mathbb{Q}$ is countable (see the proof of Proposition 4.8.6); fix an injection $\iota : \mathbb{Q} \to \mathbb{N}$ and send c to the rational number $q \in J_c$ with the smallest $\iota(q)$, which exists as J_c contains rational numbers. This map is injective, since the J_c are disjoint, so the interior discontinuities form a countable set. Adding the at most two endpoints of I keeps it countable. □

Example 27.4.6 (Thomae's function)**.** Let $T(x) = 1/q$ if $x = p/q$ with $p \in \mathbb{Z}$, $q \geq 1$ coprime, and $T(x) = 0$ for irrational x. Then T is continuous at every irrational number and discontinuous at every rational number.

Indeed, at a rational a, $T(a) > 0$, but there are irrational $y_n \to a$ (Counterexample 27.3.10) with $T(y_n) = 0$. At an irrational a, let $\varepsilon > 0$. The rationals p/q in $(a-1, a+1)$ with $q \leq 1/\varepsilon$ are finitely many, and none equals a; let δ be smaller than 1 and than their distances to a. For $|x - a| < \delta$, either x is irrational and $T(x) = 0$, or $x = p/q$ with $q > 1/\varepsilon$, so $|T(x) - T(a)| = 1/q < \varepsilon$.

Remark 27.4.7. There is no function $\mathbb{R} \to \mathbb{R}$ that is continuous exactly at the rational numbers: the set of points of continuity of any function is a countable intersection of open sets, and $\mathbb{Q}$ is not, by the Baire category theorem (Theorem 18.7.8). By contrast, $x\mathbf{1}_{\mathbb{Q}}(x)$ is continuous exactly at 0 (Exercise 27.16.10).

Theorem 27.4.8 (Bolzano's theorem on zeros)**.** *Let $f : [a, b] \to \mathbb{R}$ be continuous with $f(a) < 0 < f(b)$. Then $f(c) = 0$ for some $c \in (a, b)$.*

Proof. We construct intervals by bisection. Let $a_0 = a$, $b_0 = b$. Given $[a_n, b_n]$ with $f(a_n) < 0 \leq f(b_n)$, let $m = (a_n + b_n)/2$; if $f(m) < 0$ put $a_{n+1} = m$, $b_{n+1} = b_n$, and otherwise $a_{n+1} = a_n$, $b_{n+1} = m$. Then $f(a_{n+1}) < 0 \leq f(b_{n+1})$, (a_n) is increasing, (b_n) is decreasing, and $b_n - a_n = (b-a)/2^n \to 0$. By Proposition 27.2.10 both converge, to the same limit $c \in [a, b]$. By continuity, $f(c) = \lim f(a_n) \leq 0$ and $f(c) = \lim f(b_n) \geq 0$ (Proposition 27.2.5(1)), so $f(c) = 0$, and $c \neq a, b$. □

Corollary 27.4.9. *Let I be an interval and $f : I \to \mathbb{R}$ continuous.*

1. *(Intermediate value theorem) f takes every value between any two of its values, so $f(I)$ is an interval.*
2. *If f is injective, it is strictly monotone.*
3. *Every continuous map $f : [a, b] \to [a, b]$ has a fixed point.*
4. *Every real polynomial of odd degree has a real root.*

Proof. (1) If $f(x) < y < f(z)$, apply Theorem 27.4.8 to $f - y$ on the interval between x and z (to $y - f$ if $x > z$). This is also the case $X = I$ of Corollary 18.5.5. (2) Let $a < b$ in I, and assume $f(a) < f(b)$ (otherwise replace f by $-f$). Let $x < y$ in I and put

$h(t) = f((1-t)b + ty) - f((1-t)a + tx)$ for $t \in [0,1]$. Since $(1-t)a + tx < (1-t)b + ty$ and f is injective, $h(t) \neq 0$ for all t. As h is continuous and $h(0) > 0$, (1) gives $h(1) = f(y) - f(x) > 0$. So f is strictly increasing. (3) $g(x) = f(x) - x$ satisfies $g(a) \geq 0 \geq g(b)$; if neither is 0, apply (1). (4) We may take $p(x) = x^{2k+1} + c_{2k}x^{2k} + \cdots + c_0$. For $|x| \geq 1 + \sum |c_i|$ we have $|c_{2k}x^{2k} + \cdots + c_0| \leq \sum |c_i|\,|x|^{2k} < |x|^{2k+1}$, so $p(x)$ has the sign of x there. Apply (1). □

Theorem 27.4.10 (Weierstrass). *A continuous function $f : [a,b] \to \mathbb{R}$ is bounded and attains its maximum and its minimum.*

Proof. If f were unbounded, there would be $x_n \in [a,b]$ with $|f(x_n)| > n$. By Theorem 27.2.12 a subsequence converges to some c, and $c \in [a,b]$ by Proposition 27.2.5(1). Then $f(x_{n_k}) \to f(c)$, so $(f(x_{n_k}))$ is bounded, a contradiction. Let $s = \sup f$ and choose x_n with $f(x_n) > s - 1/(n+1)$; a subsequence converges to some $c \in [a,b]$, and $f(c) = \lim f(x_{n_k}) = s$ by the squeeze theorem. The minimum is the maximum of $-f$. (This is the case $X = [a,b]$ of Corollary 18.6.6.) □

Counterexample 27.4.11. Each hypothesis of Theorem 27.4.10 is needed: x on $(0,1)$ attains neither its supremum nor its infimum; $1/x$ on $(0,1]$ is unbounded; x on $[0,+\infty)$ is unbounded; and the function on $[0,1]$ equal to x for $x < 1$ and to 0 at 1 has supremum 1, which is not attained.

Definition 27.4.12. A function $f : D \to \mathbb{R}$ is *uniformly continuous* if for every $\varepsilon > 0$ there is $\delta > 0$ with $|f(x) - f(y)| < \varepsilon$ for all $x, y \in D$ with $|x - y| < \delta$. It is *Lipschitz* with constant $K \geq 0$ if $|f(x) - f(y)| \leq K|x - y|$ for all $x, y \in D$.

Proposition 27.4.13. *Let $f : D \to \mathbb{R}$.*

1. *Lipschitz functions are uniformly continuous, and uniformly continuous functions are continuous.*
2. *f is uniformly continuous if and only if $f(x_n) - f(y_n) \to 0$ for all sequences (x_n), (y_n) in D with $x_n - y_n \to 0$.*
3. *(Heine–Cantor) If $D = [a,b]$ and f is continuous, then f is uniformly continuous.*
4. *A uniformly continuous function maps Cauchy sequences to Cauchy sequences. A uniformly continuous $f : (a,b) \to \mathbb{R}$ on a bounded interval extends to a continuous function on $[a,b]$.*

Proof. (1) Take $\delta = \varepsilon/K$ (any δ if $K = 0$); the second statement is clear. (2) If f is uniformly continuous and $x_n - y_n \to 0$, eventually $|x_n - y_n| < \delta$ and so $|f(x_n) - f(y_n)| < \varepsilon$. If f is not uniformly continuous, there is $\varepsilon > 0$ and, for each n, points x_n, y_n with $|x_n - y_n| < 1/(n+1)$ and $|f(x_n) - f(y_n)| \geq \varepsilon$. (3) If not, take x_n, y_n as in the last sentence. By Theorem 27.2.12, $x_{n_k} \to c \in [a,b]$, and then $y_{n_k} \to c$. By continuity $f(x_{n_k}) - f(y_{n_k}) \to f(c) - f(c) = 0$, a contradiction. (4) If (x_n) is Cauchy and δ corresponds to ε, eventually $|x_n - x_m| < \delta$, so $|f(x_n) - f(x_m)| < \varepsilon$. For the extension to a: for any sequence $x_n \to a$ in (a,b), $(f(x_n))$ is Cauchy, hence converges; by (2), two such sequences give the same limit (as $x_n - y_n \to 0$), say L. By Theorem 27.3.4, $\lim_{x \to a^+} f(x) = L$, and setting $f(a) = L$ gives a function continuous at a; similarly at b. □

Counterexample 27.4.14.

1. $f(x) = x^2$ on $\mathbb{R}$ is continuous but not uniformly continuous: with $x_n = n + 1$ and $y_n = n + 1 + 1/(n+1)$, $x_n - y_n \to 0$ but $f(y_n) - f(x_n) \geq 2$.
2. $f(x) = 1/x$ on $(0,1)$ is continuous but not uniformly continuous: with $x_n = 1/(n+2)$ and $y_n = 1/(n+3)$, $f(y_n) - f(x_n) = 1$; it has no continuous extension to $[0,1)$, in accordance with Proposition 27.4.13(4).
3. $f(x) = \sqrt{x}$ on $[0,+\infty)$ is uniformly continuous, since $|\sqrt{x} - \sqrt{y}| \leq \sqrt{|x-y|}$, but not Lipschitz, since $\sqrt{x}/x \to +\infty$ as $x \to 0^+$. So the implications in (1) are strict.

27.5 Upper and lower limits, and series

Definition 27.5.1. For a real sequence (a_n) let $\limsup_n a_n = \inf_n \sup_{k\geq n} a_k$ and $\liminf_n a_n = \sup_n \inf_{k\geq n} a_k$, with values in the extended real line.

Proposition 27.5.2. *1. A bounded monotone real sequence converges, to its supremum or infimum.*

2. (a_n) converges to $a \in \mathbb{R}$ if and only if $\limsup a_n = \liminf a_n = a$.

3. (Bolzano–Weierstrass) Every bounded sequence in $\mathbb{R}^n$ has a convergent subsequence.

Proof. (1) is Proposition 27.2.10. (2) The sequences $\sup_{k\geq n} a_k$ and $\inf_{k\geq n} a_k$ are monotone and bracket a_n. If both converge to a, so does a_n; conversely, if $|a_k - a| < \varepsilon$ for $k \geq N$, both lie within ε of a for $n \geq N$. (3) A bounded set lies in a closed cube, which is compact (Theorem 18.6.5) and hence sequentially compact (Theorem 18.7.4). □

Definition 27.5.3. Let V be a normed space. A series $\sum_n v_n$ *converges* to s if the partial sums $s_N = \sum_{n\leq N} v_n$ converge to s, and it *converges absolutely* if $\sum_n \|v_n\| < \infty$.

Proposition 27.5.4. *Let V be a Banach space.*

1. *An absolutely convergent series converges, and every rearrangement $\sum_n v_{\sigma(n)}$ (σ a bijection of $\mathbb{N}$) converges to the same sum.*

2. *(Comparison) If $\|v_n\| \leq c_n$ and $\sum c_n < \infty$, then $\sum v_n$ converges absolutely.*

3. *(Root and ratio tests) If $\limsup \|v_n\|^{1/n} < 1$, or $v_n \neq 0$ and $\limsup \|v_{n+1}\|/\|v_n\| < 1$, then $\sum v_n$ converges absolutely. If $\limsup \|v_n\|^{1/n} > 1$, it diverges.*

4. *(Geometric series) For $z \in \mathbb{C}$ with $|z| < 1$, $\sum_n z^n = 1/(1-z)$.*

5. *(Weierstrass M-test) If $f_n \colon X \to V$ satisfy $\sup_x \|f_n(x)\| \leq M_n$ with $\sum M_n < \infty$, then $\sum f_n$ converges uniformly.*

Proof. (1) $\|s_M - s_N\| \leq \sum_{N<n\leq M} \|v_n\|$, so the partial sums are Cauchy. For a rearrangement, given ε choose N with $\sum_{n\geq N} \|v_n\| < \varepsilon$ and then M with $\{0,\dots,N-1\} \subseteq \sigma(\{0,\dots,M\})$; for $m \geq M$, $\|\sum_{k\leq m} v_{\sigma(k)} - s_{N-1}\| \leq \sum_{n\geq N} \|v_n\| < \varepsilon$, and $\|s_{N-1} - s\| \leq \varepsilon$. (2) follows from (1). (3) If $\limsup \|v_n\|^{1/n} < q < 1$, then $\|v_n\| \leq q^n$ for large n; compare with $\sum q^n$ using (4). If the ratio limsup is $< q < 1$, then $\|v_n\| \leq Cq^n$ for large n. If $\limsup \|v_n\|^{1/n} > 1$, then $\|v_n\| > 1$ infinitely often, so $v_n \not\to 0$ and the partial sums are not Cauchy. (4) $(1-z)\sum_{n\leq N} z^n = 1 - z^{N+1}$, and $|z|^N \to 0$: if $0 < |z| < 1$ write $1/|z| = 1 + h$, so $|z|^{-N} \geq 1 + Nh$. (5) The partial sums are bounded and uniformly Cauchy, and the space $B(X,V)$ of bounded maps is complete (Proposition 18.7.2). □

Proposition 27.5.5 (More convergence tests)**.** *Let (a_n), (b_n) be sequences of real numbers.*

1. *If $\sum a_n$ converges, then $a_n \to 0$. The converse fails: the harmonic series $\sum_{n\geq 1} 1/n$ diverges.*

2. *(Limit comparison) If $a_n, b_n > 0$ and $a_n/b_n \to L \in (0,\infty)$, then $\sum a_n$ and $\sum b_n$ both converge or both diverge. In particular this holds if $a_n \sim b_n$, that is, $a_n/b_n \to 1$.*

3. *(Cauchy condensation) If $a_1 \geq a_2 \geq \cdots \geq 0$, then $\sum_{n\geq 1} a_n$ converges if and only if $\sum_{k\geq 0} 2^k a_{2^k}$ converges. Consequently $\sum_{n\geq 1} n^{-p}$ converges if and only if $p > 1$, and $\sum_{n\geq 2} 1/(n(\log n)^p)$ converges if and only if $p > 1$.*

4. *(Ratio and root) If $a_n > 0$, then $\liminf \frac{a_{n+1}}{a_n} \le \liminf a_n^{1/n} \le \limsup a_n^{1/n} \le \limsup \frac{a_{n+1}}{a_n}$; so whenever the ratio test applies, the root test does too. If $a_{n+1} \ge a_n > 0$ for large n, the series diverges. If the limit of the ratios or of the roots is 1, no conclusion is possible: $\sum 1/n$ diverges and $\sum 1/n^2$ converges, and both have limit 1.*

5. *(Dirichlet) If $b_n \in \mathbb{C}$ have bounded partial sums $B_n = \sum_{k\le n} b_k$ and $a_n \ge a_{n+1} \to 0$, then $\sum a_n b_n$ converges. For $b_n = (-1)^n$ this is the alternating series test (Lemma 27.5.7 below).*

Proof. (1) $a_n = s_n - s_{n-1} \to s - s = 0$. For the harmonic series, $s_{2n} - s_n = \sum_{n<k\le 2n} \frac{1}{k} \ge n \cdot \frac{1}{2n} = \frac{1}{2}$, so the partial sums are not Cauchy.

(2) A series of positive terms converges if and only if its partial sums are bounded (Proposition 27.5.2). For large n, $\frac{L}{2} b_n \le a_n \le 2L b_n$, so the partial sums are bounded for both series or for neither.

(3) For $2^k \le n < 2^{k+1}$ there are 2^k terms, each between $a_{2^{k+1}}$ and a_{2^k}, so $\frac{1}{2} 2^{k+1} a_{2^{k+1}} \le \sum_{n=2^k}^{2^{k+1}-1} a_n \le 2^k a_{2^k}$. Summing over $k \le K$ shows that the partial sums of the two series bound each other, up to a factor 2 and the term a_1. For $a_n = n^{-p}$ with $p > 0$, $2^k a_{2^k} = (2^{1-p})^k$, a geometric series converging if and only if $p > 1$; for $p \le 0$ the terms do not tend to 0. For $a_n = 1/(n(\log n)^p)$, $2^k a_{2^k} = (k \log 2)^{-p}$, which reduces to the previous case.

(4) If $\limsup a_{n+1}/a_n < q$, then $a_{n+1} \le q a_n$ for $n \ge N$, so $a_n \le C q^n$ and $a_n^{1/n} \le C^{1/n} q \to q$; hence $\limsup a_n^{1/n} \le q$. The inequality for the lim inf is proved in the same way. If a_n is eventually nondecreasing and positive, it does not tend to 0.

(5) Summation by parts: for $m \le N$, $\sum_{n=m}^{N} a_n b_n = a_N B_N - a_m B_{m-1} + \sum_{n=m}^{N-1} (a_n - a_{n+1}) B_n$. With $|B_n| \le M$ and $a_n - a_{n+1} \ge 0$, the absolute value is at most $M(a_N + a_m + (a_m - a_N)) = 2M a_m$, which tends to 0; so the partial sums are Cauchy. □

Example 27.5.6. *Combining tests.* The tests are sufficient conditions, and in practice one combines them: first replace a_n by a simpler sequence with the same behaviour (limit comparison with an asymptotic equivalent), then apply the ratio, root or condensation test to it.

1. $\sum n!/n^n$: the ratio is $(n/(n+1))^n = (1 + 1/n)^{-n} \to 1/e < 1$, so the series converges.

2. $\sum \sin(1/n)$ diverges and $\sum(1 - \cos(1/n))$ converges, by limit comparison with $\sum 1/n$ and $\sum 1/(2n^2)$, since $\sin t/t \to 1$ and $(1 - \cos t)/t^2 \to \frac{1}{2}$ as $t \to 0$.

3. $\sqrt{n+1} - \sqrt{n} = 1/(\sqrt{n+1} + \sqrt{n}) \sim 1/(2\sqrt{n})$; so $\sum(\sqrt{n+1} - \sqrt{n})$ diverges (its partial sums are $\sqrt{N+1} - 1$) and $\sum(\sqrt{n+1} - \sqrt{n})/n$ converges, by comparison with $\sum n^{-3/2}$.

4. $\sum_{n\ge 1} \sin(n)/n$ converges by Dirichlet's test: from $2 \sin \frac{1}{2} \sin k = \cos(k - \frac{1}{2}) - \cos(k + \frac{1}{2})$ the partial sums of $\sum \sin k$ telescope and are bounded by $1/\sin \frac{1}{2}$. It does not converge absolutely, since $|\sin n| \ge \sin^2 n = \frac{1}{2}(1 - \cos 2n)$ and $\sum \cos(2n)/n$ converges by the same argument while $\sum 1/n$ diverges.

5. $\sum n^2/2^n$ converges by the root test ($n^{2/n} \to 1$), and $\sum 2^n/n^2$ diverges since its terms tend to ∞.

Lemma 27.5.7 (Alternating series)**.** *If $t_0 \ge t_1 \ge \cdots \ge 0$ and $t_k \to 0$, then $S = \sum_k (-1)^k t_k$ converges and $S_{2m+1} \le S \le S_{2m}$ for all m, where S_N are the partial sums.*

Proof. $S_{2m+2} - S_{2m} = -t_{2m+1} + t_{2m+2} \le 0$ and $S_{2m+3} - S_{2m+1} = t_{2m+2} - t_{2m+3} \ge 0$, and $S_{2m+1} = S_{2m} - t_{2m+1} \le S_{2m}$. So the even partial sums decrease, the odd ones increase, every odd one is below every even one, and their difference tends to 0. □

Rearranging series. A finite sum does not depend on the order of its terms, and by Proposition 27.5.4(1) neither does the sum of an absolutely convergent series. For series that converge but not absolutely the order matters, and Riemann discovered that it matters as much as it possibly could: by reordering the terms one can make the sum anything one likes. A series $\sum_n a_n$ of real numbers is *conditionally convergent* if it converges but $\sum_n |a_n| = \infty$; the alternating harmonic series $\sum_{n\geq 1}(-1)^{n+1}/n$ is the basic example (Lemma 27.5.7 and Proposition 27.5.5(1)). Write $a^+ = \max(a, 0)$ and $a^- = \max(-a, 0)$ for the positive and negative parts of a real number, so that $a = a^+ - a^-$ and $|a| = a^+ + a^-$.

Lemma 27.5.8. *If $\sum_n a_n$ is a conditionally convergent series of real numbers, then $a_n \to 0$ and $\sum_n a_n^+ = \sum_n a_n^- = \infty$. In particular infinitely many a_n are positive and infinitely many are negative.*

Proof. $a_n \to 0$ by Proposition 27.5.5(1). If $\sum_n a_n^+$ were finite, then $\sum_n a_n^- = \sum_n (a_n^+ - a_n)$ would converge, being the difference of two convergent series, and so would $\sum_n |a_n| = \sum_n (a_n^+ + a_n^-)$, a contradiction. The same argument applies to $\sum_n a_n^-$. A series of non-negative terms with only finitely many nonzero terms is finite, so infinitely many a_n^+ and infinitely many a_n^- are nonzero. □

So the positive terms alone have infinite sum, and so do the negative terms alone; the series converges only because they are interleaved so as to cancel. This is what a rearrangement can exploit.

Theorem 27.5.9 (Riemann's rearrangement theorem)**.** *Let $\sum_n a_n$ be a conditionally convergent series of real numbers, and let $-\infty \leq \alpha \leq \beta \leq \infty$. There is a bijection $\sigma : \mathbb{N} \to \mathbb{N}$ such that the partial sums $T_N = \sum_{n\leq N} a_{\sigma(n)}$ satisfy*

$$\liminf_{N\to\infty} T_N = \alpha \qquad \text{and} \qquad \limsup_{N\to\infty} T_N = \beta.$$

In particular, for every $c \in \mathbb{R}$ some rearrangement converges to c, and some rearrangements diverge to ∞ and to $-\infty$.

Proof. Targets. Choose real numbers $\alpha_k \to \alpha$ and $\beta_k \to \beta$ with $\alpha_k < \beta_k$ and $\alpha_k < \beta_{k+1}$ for all $k \geq k_0$: put $\beta_k = \beta + \frac{1}{k}$, k or $-k$ according as β is finite, $+\infty$ or $-\infty$, and $\alpha_k = \alpha - \frac{1}{k}$, $k-1$ or $-k-2$ according as α is finite, $+\infty$ or $-\infty$. One checks the inequalities case by case for k large (recall $\alpha \leq \beta$; for instance if $\alpha = \beta = -\infty$, then $\alpha_k = -k-2 < -k-1 = \beta_{k+1}$).

Construction. Let $p_1 < p_2 < \cdots$ be the indices n with $a_n \geq 0$ and $q_1 < q_2 < \cdots$ those with $a_n < 0$; both lists are infinite by Lemma 27.5.8, and together they contain every index once. We build the rearrangement in stages $k = k_0, k_0+1, \ldots$, each consisting of an *up step* and a *down step*. In the up step of stage k we append the next unused terms a_{p_j}, in order, as long as the running sum is $\leq \beta_k$, stopping as soon as it exceeds β_k. In the down step we append the next unused terms a_{q_j}, in order, until the running sum is $< \alpha_k$. Each step stops after finitely many terms: the unused positive terms are all but finitely many of the a_n^+, so their sum is still infinite by Lemma 27.5.8, and likewise for the negative terms.

Every index is used. A down step adds at least one term, because it starts with a sum $> \beta_k > \alpha_k$; an up step of stage $k+1$ adds at least one term, because it starts with a sum $< \alpha_k < \beta_{k+1}$. So infinitely many p_j and infinitely many q_j are used, and since each list is used in order, all of them are. Hence the order in which the terms are appended defines a bijection $\sigma : \mathbb{N} \to \mathbb{N}$.

The partial sums. Let U_k be the running sum at the end of the up step of stage k and L_k the one at the end of the down step. If the up step added terms, then just before its last term a_{u_k} the sum was $\leq \beta_k$, so

$$\beta_k < U_k \leq \beta_k + a_{u_k}, \qquad \text{and similarly} \qquad \alpha_k + a_{l_k} \leq L_k < \alpha_k,$$

with $a_{l_k} < 0$ the last term of the down step (for $k > k_0$ the up step always adds terms, as shown above). The indices u_k and l_k are distinct for distinct k, so they tend to ∞, and $a_{u_k}, a_{l_k} \to 0$ because $a_n \to 0$. Hence $U_k - \beta_k \to 0$ and $L_k - \alpha_k \to 0$, so $U_k \to \beta$ and $L_k \to \alpha$ (in the extended sense when α or β is infinite). Within an up step the running sum increases, and within a down step it decreases; so for N in the up step of stage k we have $L_{k-1} \le T_N \le U_k$, and for N in the down step $L_k \le T_N \le U_k$. Therefore $\limsup_N T_N \le \limsup_k U_k = \beta$ and $\liminf_N T_N \ge \liminf_k L_k = \alpha$; and the values $T_N = U_k$ and $T_N = L_k$ occur for every k, so equality holds in both. The last statement is the case $\alpha = \beta$. □

Corollary 27.5.10. *A series $\sum_n a_n$ of real numbers is absolutely convergent if and only if every rearrangement of it converges, and if and only if all its rearrangements converge to the same sum.*

Proof. If $\sum_n |a_n| < \infty$, every rearrangement converges to the same sum by Proposition 27.5.4(1). If $\sum_n |a_n| = \infty$, either the series diverges, and then the identity rearrangement does not converge, or it is conditionally convergent, and then Theorem 27.5.9 with $\alpha = \beta = \infty$ gives a rearrangement that diverges. □

Example 27.5.11.

1. Let $S = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots$. By Lemma 27.5.7, $\frac{1}{2} = S_1 \le S \le S_0 = 1$, so $S \ne 0$. Take one positive term followed by two negative ones:
$$1 - \frac{1}{2} - \frac{1}{4} + \frac{1}{3} - \frac{1}{6} - \frac{1}{8} + \frac{1}{5} - \frac{1}{10} - \frac{1}{12} + \cdots$$
Every term of S occurs exactly once: the odd denominators in order, and the even denominators in order, two at a time. The k-th group of three terms is $\frac{1}{2k-1} - \frac{1}{4k-2} - \frac{1}{4k} = \frac{1}{4k-2} - \frac{1}{4k} = \frac{1}{2}\left(\frac{1}{2k-1} - \frac{1}{2k}\right)$. So the partial sums after $3m$ terms are half the partial sums of S after $2m$ terms, and tend to $\frac{1}{2}S$; the partial sums in between differ from these by at most two terms, which tend to 0. So this rearrangement converges to $\frac{1}{2}S \ne S$.

2. The proof of the theorem is an algorithm. To rearrange S so that it converges to $c = 2$: take $1 + \frac{1}{3} + \frac{1}{5} + \cdots$ until the sum exceeds 2, which happens at $1 + \frac{1}{3} + \cdots + \frac{1}{15} \approx 2.02$ (eight terms), then subtract $\frac{1}{2}$ to get $\approx 1.52 < 2$, then add $\frac{1}{17} + \frac{1}{19} + \cdots$ until the sum exceeds 2 again, and so on. The positive terms are used much faster than the negative ones. This is how it must be: a rearrangement with a larger sum takes more positive terms per negative term, just as in (1) taking fewer positive terms per negative term gave a smaller sum.

3. For complex series the theorem fails as stated: the rearrangements of $\sum_n i(-1)^{n+1}/n$ have as sums exactly the points of the imaginary axis $i\mathbb{R}$, by the theorem applied to the real series $\sum_n (-1)^{n+1}/n$. For series in $\mathbb{R}^m$ the possible sums of rearrangements form a more complicated set, which can be a line in the plane even when the series does not lie on a line, as the example $\sum_n \left((-1)^{n+1}/n, (-1)^{n+1}/n + 1/n^2\right)$ shows: the second coordinate differs from the first by an absolutely convergent series, whose sum does not change, so every sum lies on the line $y = x + \sum_n 1/n^2$, and every point of it occurs.

Proposition 27.5.12 (Cauchy product)**.** *If $\sum a_n$ and $\sum b_n$ are absolutely convergent series in $\mathbb{C}$, then $c_n = \sum_{k=0}^{n} a_k b_{n-k}$ defines an absolutely convergent series with $\sum c_n = (\sum a_n)(\sum b_n)$.*

Proof. Let $A = \sum |a_n|$ and $B = \sum |b_n|$. Then $\sum_{n \le N} |c_n| \le AB$, so $\sum c_n$ converges absolutely. The difference $\sum_{n \le 2N} c_n - (\sum_{k \le N} a_k)(\sum_{l \le N} b_l)$ is the sum of $a_k b_l$ over $k + l \le 2N$ with $k > N$ or $l > N$, bounded by $B \sum_{k>N} |a_k| + A \sum_{l>N} |b_l| \to 0$. □

Theorem 27.5.13. *Let $a_n \in \mathbb{C}$ and $R = 1/\limsup_n |a_n|^{1/n} \in [0, \infty]$, the* radius of convergence. *The power series $\sum_n a_n z^n$ converges absolutely for $|z| < R$, uniformly on $|z| \le r$ for every $r < R$, and diverges for $|z| > R$. The series $\sum_n n a_n z^{n-1}$ and $\sum_n n^2 a_n z^n$ have the same radius of convergence.*

Proof. For $|z| \le r < R$ choose $r < q < R$; then $|a_n| \le q^{-n}$ for large n, so $|a_n z^n| \le (r/q)^n$, and the M-test applies. For $|z| > R$, $\limsup |a_n z^n|^{1/n} > 1$. Finally $n^{1/n} \to 1$: writing $n^{1/n} = 1 + h_n$, the binomial formula gives $n \ge \binom{n}{2} h_n^2$, so $h_n^2 \le 2/(n-1)$. Hence $\limsup |n^k a_n|^{1/n} = \limsup |a_n|^{1/n}$. □

27.6 Differentiation in one variable

Definition 27.6.1. Let $I \subseteq \mathbb{R}$ be an interval with more than one point and $f : I \to \mathbb{K}^m$. Then f is *differentiable* at $a \in I$ with derivative $f'(a)$ if $(f(x) - f(a))/(x-a) \to f'(a)$ as $x \to a$ in $I \setminus \{a\}$. Equivalently, there is a function $\phi : I \to \mathbb{K}^m$, continuous at a, with $f(x) - f(a) = \phi(x)(x-a)$; then $f'(a) = \phi(a)$. The same definition with I replaced by an open subset of $\mathbb{C}$ and x complex defines the *complex derivative*.

Proposition 27.6.2. *Differentiable functions are continuous. Sums, products and quotients (where the denominator does not vanish) of differentiable scalar functions are differentiable with the usual formulas, and if f is differentiable at a and g at $f(a)$, then $(g \circ f)'(a) = g'(f(a))f'(a)$.*

Proof. Write $f(x) - f(a) = \phi(x)(x-a)$ and $g(y) - g(b) = \psi(y)(y-b)$ with ϕ, ψ continuous at $a, b = f(a)$. Continuity is clear. For products, $fg(x) - fg(a) = (\phi(x)g(x) + f(a)\chi(x))(x-a)$ if $g(x) - g(a) = \chi(x)(x-a)$. For $1/f$, $1/f(x) - 1/f(a) = -\phi(x)(x-a)/(f(x)f(a))$. For composites, $g(f(x)) - g(f(a)) = \psi(f(x))\phi(x)(x-a)$ and $\psi \circ f$ is continuous at a. Evaluate the continuous factors at a. □

Definition 27.6.3. Let $f : I \to \mathbb{R}$ on an interval I. Then f has a *local maximum* at $c \in I$ if there is $\delta > 0$ with $f(x) \le f(c)$ for all $x \in I$ with $|x - c| < \delta$, a *strict* local maximum if $f(x) < f(c)$ for these $x \ne c$, and similarly for (strict) local minima. A *local extremum* is a local maximum or minimum.

Lemma 27.6.4 (Fermat)**.** *If $f : I \to \mathbb{R}$ has a local extremum at an interior point c of I and is differentiable at c, then $f'(c) = 0$.*

Proof. Say c is a local maximum. For $x > c$ close to c, $(f(x) - f(c))/(x-c) \le 0$, so $f'(c) \le 0$ by Corollary 27.3.5(2); for $x < c$ the quotient is ≥ 0, so $f'(c) \ge 0$. □

Counterexample 27.6.5. The converse fails: $f(x) = x^3$ has $f'(0) = 0$ and no extremum at 0. The hypothesis that c is interior is needed: $f(x) = x$ on $[0,1]$ has a maximum at 1 with $f'(1) = 1$. And $|x|$ has a minimum at 0, where it is not differentiable.

Theorem 27.6.6 (Mean value theorem)**.** *Let $f, g : [a,b] \to \mathbb{R}$ be continuous and differentiable on (a,b).*

1. *(Rolle) If $f(a) = f(b)$, then $f'(\xi) = 0$ for some $\xi \in (a,b)$.*
2. *There is $\xi \in (a,b)$ with $f(b) - f(a) = f'(\xi)(b-a)$, and (Cauchy) some η with $(f(b) - f(a))g'(\eta) = (g(b) - g(a))f'(\eta)$.*
3. *If $f' = 0$ on (a,b), f is constant; if $f' \ge 0$ (> 0), f is increasing (strictly increasing).*

Proof. (1) By Corollary 18.6.6, f attains a maximum and a minimum; if both are at endpoints, f is constant. Otherwise one is at some $\xi \in (a,b)$, and $f'(\xi) = 0$ by Lemma 27.6.4. (2) Apply (1) to $f(x) - \frac{f(b)-f(a)}{b-a}(x-a)$, and to $(f(b) - f(a))g(x) - (g(b) - g(a))f(x)$. (3) Apply (2) on subintervals. □

Remark 27.6.7. Both hypotheses of (3) matter. On a set that is not an interval a function with zero derivative need not be constant: $f = 0$ on $(0,1)$ and $f = 1$ on $(2,3)$. And "$f' = 0$" must hold at every point: the Cantor function (Chapter 28) is continuous, nondecreasing and nonconstant on $[0,1]$, with $f' = 0$ outside a set of measure zero. On the other hand finitely many exceptional points do not matter: if f is continuous on $[a,b]$ and $f' = 0$ except at $c_1 < \cdots < c_k$, applying (3) on each interval between consecutive points and using continuity shows that f is constant.

Proposition 27.6.8. *Let $f : I \to \mathbb{R}$ be continuous and strictly monotone. Then $J = f(I)$ is an interval, $f^{-1} : J \to I$ is continuous, and if f is differentiable at a with $f'(a) \neq 0$, then f^{-1} is differentiable at $f(a)$ with derivative $1/f'(a)$.*

Proof. J is an interval by Corollary 18.5.5. A strictly monotone bijection of intervals maps subintervals onto subintervals, so f^{-1} maps open subintervals of J (relative to J) to open subintervals of I, and is continuous. Write $f(x) - f(a) = \phi(x)(x-a)$; strict monotonicity gives $\phi(x) \neq 0$ for $x \neq a$, and $\phi(a) = f'(a) \neq 0$. So $f^{-1}(y) - a = (y - f(a))/\phi(f^{-1}(y))$ with $1/(\phi \circ f^{-1})$ continuous at $f(a)$. □

Proposition 27.6.9 (Limits of derivatives)**.** *Let $f : [a,b) \to \mathbb{R}$ be continuous, differentiable on (a,b), and suppose $\lim_{x\to a^+} f'(x) = L \in \mathbb{R}$. Then f is differentiable at a (from the right) with $f'(a) = L$. Consequently, if f is differentiable on an open interval containing c and f' has one-sided limits at c, both equal $f'(c)$: a derivative has neither removable nor jump discontinuities.*

Proof. For $a < x < b$, the mean value theorem gives $\xi_x \in (a,x)$ with $(f(x) - f(a))/(x-a) = f'(\xi_x)$. If $x_n \to a^+$, then $\xi_{x_n} \to a^+$ by the squeeze theorem, so $f'(\xi_{x_n}) \to L$; by Theorem 27.3.4, the difference quotient tends to L. For the second statement, apply this on each side of c. □

Theorem 27.6.10 (de l'Hôpital)**.** *Let $f, g : (a,b) \to \mathbb{R}$ be differentiable, with $-\infty \le a < b \le +\infty$, and $g'(x) \neq 0$ for all x. Suppose that $\lim_{x\to a^+} f'(x)/g'(x) = L \in \bar{\mathbb{R}}$ and that either*

1. *$\lim_{x\to a^+} f(x) = \lim_{x\to a^+} g(x) = 0$, or*
2. *$\lim_{x\to a^+} |g(x)| = +\infty$ and $L \in \mathbb{R}$.*

Then $\lim_{x\to a^+} f(x)/g(x) = L$. The same holds for left limits at b, and hence for two-sided limits.

Proof. Since $g' \neq 0$, g is injective on (a,b) by Rolle's theorem, so $g(x) \neq g(y)$ for $x \neq y$, and by the Cauchy mean value theorem (Theorem 27.6.6(2)), for $x < y$ in (a,b) there is $\xi \in (x,y)$ with

$$\frac{f(x) - f(y)}{g(x) - g(y)} = \frac{f'(\xi)}{g'(\xi)}. \tag{27.1}$$

Case (1) with $a \in \mathbb{R}$: extend f and g by $f(a) = g(a) = 0$; they become continuous on $[a,b)$, and (27.1) holds for $x = a$ as well, with $g(y) \neq 0$ for $y > a$ by Rolle's theorem. Let $y_n \to a^+$ and choose $\xi_n \in (a, y_n)$ with $f(y_n)/g(y_n) = f'(\xi_n)/g'(\xi_n)$. Then $\xi_n \to a^+$, so $f(y_n)/g(y_n) \to L$, and Theorem 27.3.4 gives the claim. If $a = -\infty$, apply the case just proved to $F(t) = f(-1/t)$ and $G(t) = g(-1/t)$ on an interval $(0,\eta)$, noting $F'(t)/G'(t) = f'(-1/t)/g'(-1/t)$ and using Proposition 27.3.6.

Case (2). Let $\varepsilon > 0$ and choose $c \in (a,b)$ with $|f'(\xi)/g'(\xi) - L| < \varepsilon$ for $a < \xi < c$. Fix $y \in (a,c)$. For $a < x < y$, (27.1) gives $Q(x) = (f(x) - f(y))/(g(x) - g(y))$ with $|Q(x) - L| < \varepsilon$. Since $|g(x)| \to +\infty$, $g(x) \neq 0$ for x close to a, and

$$\frac{f(x)}{g(x)} - L = \big(Q(x) - L\big)\Big(1 - \frac{g(y)}{g(x)}\Big) - L\frac{g(y)}{g(x)} + \frac{f(y)}{g(x)}.$$

As $x \to a^+$ with y fixed, the last two terms tend to 0 and $1 - g(y)/g(x) \to 1$, so $|f(x)/g(x) - L| < 2\varepsilon$ for x close to a. Left limits at b follow by applying the result to $x \mapsto f(-x)$, $g(-x)$. □

Theorem 27.6.11 (Darboux). *Let $f : [a, b] \to \mathbb{R}$ be differentiable, with one-sided derivatives at the endpoints. Then f' takes every value between $f'(a)$ and $f'(b)$.*

Proof. Let $f'(a) < y < f'(b)$ (the other case follows by passing to $-f$) and $g(x) = f(x) - yx$. Then $g'(a) < 0 < g'(b)$. By Theorem 27.4.10, g attains a minimum at some $c \in [a, b]$. As $g'(a) < 0$, $(g(x) - g(a))/(x - a) < 0$ for $x > a$ close to a (Proposition 27.3.3(2)), so $g(x) < g(a)$ and $c \neq a$; similarly $c \neq b$. By Lemma 27.6.4, $g'(c) = 0$, that is, $f'(c) = y$. □

Theorem 27.6.12 (Taylor). *Let $f : [a, x] \to \mathbb{R}$ (or $[x, a]$) have n continuous derivatives, with $f^{(n+1)}$ existing on the open interval. Then there is ξ strictly between a and x with*

$$f(x) = \sum_{k=0}^{n} \frac{f^{(k)}(a)}{k!}(x - a)^k + \frac{f^{(n+1)}(\xi)}{(n + 1)!}(x - a)^{n+1}.$$

Proof. Let $g(t) = f(x) - \sum_{k\le n} f^{(k)}(t)(x - t)^k/k! - M(x - t)^{n+1}/(n + 1)!$, with M chosen so that $g(a) = 0$. Also $g(x) = 0$. In the derivative the sum telescopes: $g'(t) = -f^{(n+1)}(t)(x - t)^n/n! + M(x - t)^n/n!$. By Rolle's theorem $g'(\xi) = 0$ for some ξ between a and x, so $M = f^{(n+1)}(\xi)$. □

Proposition 27.6.13 (Taylor's formula with Peano remainder). *Let $n \geq 1$, let $f : I \to \mathbb{R}$ be $n - 1$ times differentiable on an interval I, and suppose $f^{(n)}(a)$ exists at a point $a \in I$. Let $T_n(x) = \sum_{k=0}^{n} f^{(k)}(a)(x - a)^k/k!$. Then*

$$\lim_{x\to a} \frac{f(x) - T_n(x)}{(x - a)^n} = 0,$$

that is, $f(x) = T_n(x) + o((x - a)^n)$ as $x \to a$.

Proof. Let $R = f - T_n$. Then R is $n - 1$ times differentiable, $R^{(k)}(a) = 0$ for $0 \leq k \leq n$, and each $R^{(k)}$ with $k \leq n - 1$ is continuous at a. For $n = 1$ the claim is $(R(x) - R(a))/(x - a) \to R'(a) = 0$. For $n \geq 2$, apply Theorem 27.6.10(1) $n - 1$ times, on each side of a, to the quotients $R^{(j)}(x)/(x - a)^{n-j}$, $0 \leq j \leq n - 2$, whose numerators and denominators tend to 0 and whose denominators have nonvanishing derivatives for $x \neq a$. It remains to see that the last quotient tends to 0:

$$\frac{R^{(n-1)}(x)}{n!\,(x - a)} = \frac{1}{n!} \cdot \frac{R^{(n-1)}(x) - R^{(n-1)}(a)}{x - a} \longrightarrow \frac{R^{(n)}(a)}{n!} = 0.$$

□

Corollary 27.6.14 (Second derivative test). *Let f be differentiable on an open interval containing c, with $f'(c) = 0$, and suppose $f''(c)$ exists. If $f''(c) > 0$, then f has a strict local minimum at c; if $f''(c) < 0$, a strict local maximum.*

Proof. By Proposition 27.6.13 with $n = 2$, $(f(x) - f(c))/(x - c)^2 \to f''(c)/2 > 0$, so $f(x) - f(c) > 0$ for $x \neq c$ close to c (Proposition 27.3.3(2)). □

Counterexample 27.6.15. If $f''(c) = 0$ the test says nothing: x^4, $-x^4$ and x^3 all have vanishing first and second derivatives at 0, and have a minimum, a maximum and no extremum there.

Definition 27.6.16. A function $f : I \to \mathbb{R}$ on an interval is *convex* if $f((1 - t)x + ty) \leq (1 - t)f(x) + tf(y)$ for all $x, y \in I$ and $t \in [0, 1]$, and *strictly convex* if the inequality is strict whenever $x \neq y$ and $0 < t < 1$. It is *(strictly) concave* if $-f$ is (strictly) convex.

Lemma 27.6.17 (Three slopes). *A function $f : I \to \mathbb{R}$ is convex if and only if for all $x < y < z$ in I,*

$$\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(x)}{z - x} \leq \frac{f(z) - f(y)}{z - y}.$$

Proof. Write $y = (1-t)x + tz$ with $t = (y-x)/(z-x) \in (0,1)$. Convexity at this triple says $(z-x)f(y) \le (z-y)f(x)+(y-x)f(z)$. Multiplying out, each of the two displayed inequalities is equivalent to this one. Since every $t \in (0,1)$ and $x < z$ arise, and the cases $t \in \{0,1\}$ or $x = y$ are trivial, the lemma follows (for $x > y$ exchange the roles). □

Proposition 27.6.18. *Let $f : I \to \mathbb{R}$ on an open interval I.*

1. *If f is convex, it is continuous, it has one-sided derivatives $f'_-(x) \le f'_+(x)$ at every point, and $f'_+(x) \le \frac{f(y)-f(x)}{y-x} \le f'_-(y)$ for $x < y$.*
2. *If f is differentiable, the following are equivalent: f is convex; f' is increasing; $f(y) \ge f(x) + f'(x)(y-x)$ for all $x, y \in I$.*
3. *If f is twice differentiable, f is convex if and only if $f'' \ge 0$; if $f'' > 0$, f is strictly convex.*
4. *(Jensen) If f is convex, $x_1, \dots, x_k \in I$, $t_i \ge 0$ and $\sum t_i = 1$, then $f(\sum t_i x_i) \le \sum t_i f(x_i)$.*

Proof. (1) By Lemma 27.6.17, the slope $s(x,y) = (f(y)-f(x))/(y-x)$ is increasing in each variable. For fixed x, $s(x,y)$ decreases as $y \downarrow x$ and is bounded below by $s(w,x)$ for any $w < x$ in I (which exists, I being open); so $f'_+(x) = \lim_{y \to x^+} s(x,y)$ exists by Proposition 27.3.9, and $f'_+(x) \ge s(w,x)$. Letting $w \uparrow x$ gives $f'_-(x)$, with $f'_-(x) \le f'_+(x)$. The inequality for $x < y$ follows from the monotonicity of slopes. The existence of one-sided derivatives implies continuity, as $f(y) - f(x) = s(x,y)(y-x) \to 0$. (2) If f is convex and differentiable, (1) gives $f'(x) = f'_+(x) \le f'_-(y) = f'(y)$ for $x < y$. If f' is increasing and $y > x$, the mean value theorem gives $f(y) - f(x) = f'(\xi)(y-x) \ge f'(x)(y-x)$; for $y < x$, $f'(\xi) \le f'(x)$ and $y - x < 0$ give the same inequality. Finally, if the tangent inequality holds, let $z = (1-t)x + ty$; adding $(1-t)$ times $f(x) \ge f(z) + f'(z)(x-z)$ and t times $f(y) \ge f(z) + f'(z)(y-z)$ gives $(1-t)f(x) + tf(y) \ge f(z)$. (3) $f'' \ge 0$ if and only if f' is increasing (Theorem 27.6.6(3) and, conversely, f'' = lim of nonnegative quotients); apply (2). If $f'' > 0$, f' is strictly increasing and the inequalities in the proof of (2) become strict for $y \ne x$, hence so does the final one for $x \ne y$, $0 < t < 1$. (4) Induction on k: for $t_k < 1$, $\sum t_i x_i = (1-t_k)\sum_{i<k} \frac{t_i}{1-t_k} x_i + t_k x_k$, and the inner point lies in I because I is an interval. □

Counterexample 27.6.19. A convex function need not be differentiable: $|x|$ has $f'_-(0) = -1 < 1 = f'_+(0)$. On a closed interval a convex function need not be continuous at the endpoints: the function equal to 0 on $[0,1)$ and to 1 at 1 is convex. The converse of the last statement of (3) fails: x^4 is strictly convex, but its second derivative vanishes at 0.

Theorem 27.6.20. *Let $f(z) = \sum_n a_n z^n$ have radius of convergence $R > 0$. Then f is complex differentiable on $\{|z| < R\}$ with $f'(z) = \sum_n n a_n z^{n-1}$. Hence f has complex derivatives of all orders there, and $a_n = f^{(n)}(0)/n!$. The same holds for real z in $(-R, R)$.*

Proof. Let $g(z) = \sum n a_n z^{n-1}$, which has radius R by Theorem 27.5.13. Fix $|z| < \rho < R$ and $h \ne 0$ with $|z| + |h| \le \rho$. By the binomial formula, $(z+h)^n - z^n - nz^{n-1}h = \sum_{k \ge 2} \binom{n}{k} z^{n-k} h^k$, and $\binom{n}{k} \le \binom{n}{2}\binom{n-2}{k-2}$ for $k \ge 2$, so its absolute value is at most $\binom{n}{2}|h|^2(|z|+|h|)^{n-2} \le n^2|h|^2\rho^{n-2}$. Hence $|(f(z+h) - f(z))/h - g(z)| \le |h| \sum_n n^2 |a_n| \rho^{n-2}$, and the last series converges. Iterating gives all derivatives, and evaluating at 0 gives a_n. □

27.7 The exponential and trigonometric functions

Definition 27.7.1. For $z \in \mathbb{C}$ let $\exp(z) = e^z = \sum_{n \ge 0} z^n/n!$ (radius of convergence ∞, by the ratio test), and for $x \in \mathbb{R}$ let $\cos x = \operatorname{Re} e^{ix}$ and $\sin x = \operatorname{Im} e^{ix}$, so that $\cos x = \sum_k (-1)^k x^{2k}/(2k)!$ and $\sin x = \sum_k (-1)^k x^{2k+1}/(2k+1)!$.

Proposition 27.7.2. *1.* $e^{z+w} = e^z e^w$, $e^z \neq 0$, $\overline{e^z} = e^{\bar z}$, *and* $\exp' = \exp$.

2. exp *restricts to a strictly increasing bijection* $\mathbb{R} \to (0,\infty)$, *whose inverse* log *is differentiable with* $\log'(x) = 1/x$ *and* $\log(xy) = \log x + \log y$.

3. $\cos^2 x + \sin^2 x = 1$, $\cos' = -\sin$, $\sin' = \cos$, *and* $\cos(x+y) = \cos x \cos y - \sin x \sin y$, $\sin(x+y) = \sin x \cos y + \cos x \sin y$.

Proof. (1) By Proposition 27.5.12 and the binomial formula, $e^z e^w = \sum_n \sum_k \frac{z^k w^{n-k}}{k!(n-k)!} = \sum_n (z+w)^n/n!$. So $e^z e^{-z} = 1$. Conjugation is continuous and commutes with the partial sums. The derivative is Theorem 27.6.20. (2) For real x, $e^x = (e^{x/2})^2 > 0$, so exp is strictly increasing by Theorem 27.6.6. For $x \geq 0$, $e^x \geq 1 + x$, and $e^{-x} = 1/e^x$; so exp is unbounded above and takes values arbitrarily close to 0, and by the intermediate value theorem its image is $(0,\infty)$. Apply Proposition 27.6.8. (3) $|e^{ix}|^2 = e^{ix}\overline{e^{ix}} = e^{ix}e^{-ix} = 1$; $(e^{ix})' = ie^{ix}$ by Theorem 27.6.20 applied to the real power series $\sum_n i^n x^n/n!$; the addition formulas are the real and imaginary parts of $e^{i(x+y)} = e^{ix}e^{iy}$. □

Theorem 27.7.3. *The function* cos *has a unique zero in* $(0,2)$*; call it* $\pi/2$. *Then* $e^{i\pi/2} = i$, *the map* $t \mapsto e^{it}$ *is a surjective continuous homomorphism* $\mathbb{R} \to S^1 = \{|z| = 1\}$ *with kernel* $2\pi\mathbb{Z}$, *and* $p(t) = e^{2\pi i t}$ *is a covering map* $\mathbb{R} \to S^1$. *Every* $z \neq 0$ *is* $re^{i\theta}$ *with* $r = |z|$ *and* θ *unique modulo* 2π.

Proof. For $0 < x \leq 2$ the terms $x^{2k+1}/(2k+1)!$ decrease, since consecutive ratios are $x^2/((2k+2)(2k+3)) < 1$; by Lemma 27.5.7, $\sin x \geq x - x^3/6 > 0$. So cos is strictly decreasing on $[0,2]$. The terms $4^k/(2k)!$ of $\cos 2$ decrease from $k = 1$ on, so $\cos 2 \leq 1 - 2 + 16/24 < 0$, while $\cos 0 = 1$; by the intermediate value theorem there is a unique zero $\pi/2 \in (0,2)$. Then $\sin(\pi/2) = 1$, so $e^{i\pi/2} = i$ and $e^{2\pi i} = i^4 = 1$.

Kernel: if $0 < t < 2\pi$, write $e^{it/4} = u + iv$ with $u, v > 0$ (as $0 < t/4 < \pi/2$). If $e^{it} = (u+iv)^4 = 1$, then $\operatorname{Im}(u+iv)^4 = 4uv(u^2 - v^2) = 0$ forces $u^2 = v^2 = 1/2$, and then $\operatorname{Re}(u+iv)^4 = u^4 - 6u^2v^2 + v^4 = -1$, a contradiction. With periodicity, the kernel is $2\pi\mathbb{Z}$.

Surjectivity: for $a + ib \in S^1$ with $a, b \geq 0$, choose $t \in [0, \pi/2]$ with $\cos t = a$ (intermediate value theorem); then $\sin t = \sqrt{1-a^2} = b$. The other quadrants are obtained by multiplying by powers of $i = e^{i\pi/2}$. For the covering property, p is injective on $[a, a+1)$ and identifies only a and $a+1$ in $[a, a+1]$, so the argument of Proposition 19.4.5 applies verbatim. The polar form follows by applying this to $z/|z|$. □

Remark 27.7.4. The proof of Theorem 19.4.6 uses only that $\mathbb{R}$ is simply connected and that the covering map has period 4 with fibres the translates of $4\mathbb{Z}$; it applies verbatim to $t \mapsto e^{2\pi i t}$, with period 1, so $\pi_1(S^1) \cong \mathbb{Z}$ is generated by the loop $t \mapsto e^{2\pi i t}$. For $x > 0$ and $s \in \mathbb{C}$ we define $x^s = e^{s \log x}$; then $\frac{d}{dx} x^s = s x^{s-1}$.

Proposition 27.7.5 (Notable limits)**.** *1.* $\lim_{x\to 0} \frac{e^x - 1}{x} = 1$, $\lim_{x\to 0} \frac{\log(1+x)}{x} = 1$, $\lim_{x\to 0} \frac{\sin x}{x} = 1$ *and* $\lim_{x\to 0} \frac{1-\cos x}{x^2} = \frac{1}{2}$.

2. For every $x \in \mathbb{R}$, $(1 + x/n)^n \to e^x$; *in particular* $(1 + 1/n)^n \to e = \exp(1)$.

3. For $k \in \mathbb{N}$ *and* $a > 0$: $x^k e^{-ax} \to 0$ *and* $(\log x)/x^a \to 0$ *as* $x \to +\infty$, *and* $x^a \log x \to 0$ *as* $x \to 0^+$.

Proof. (1) The first three are the derivatives of exp at 0, of log at 1 and of sin at 0 (Proposition 27.7.2), which are $e^0 = 1$, $1/1$ and $\cos 0 = 1$. For the last, apply Theorem 27.6.10(1): $\frac{1-\cos x}{x^2}$ has the same limit as $\frac{\sin x}{2x} \to \frac{1}{2}$. (2) For $x = 0$ this is clear. Otherwise, for $n > |x|$, $1 + x/n > 0$ and $(1 + x/n)^n = \exp(n \log(1 + x/n))$, with $n \log(1 + x/n) = x \cdot \frac{\log(1+x/n)}{x/n} \to x$ by (1) and Theorem 27.3.4 (as $x/n \to 0$ and $x/n \neq 0$). By continuity of exp, $(1+x/n)^n \to e^x$. (3) For $x > 0$,

$e^{ax} \geq (ax)^{k+1}/(k+1)!$, one term of the exponential series, so $0 < x^k e^{-ax} \leq (k+1)!/(a^{k+1}x) \to 0$. For $x = e^t$, $(\log x)/x^a = te^{-at}$, which tends to 0 as $t \to +\infty$ by the case $k = 1$; since $\log x \to +\infty$ as $x \to +\infty$, Proposition 27.3.6 applies. Similarly $x^a \log x = -te^{-at}$ for $x = e^{-t}$, and $t \to +\infty$ as $x \to 0^+$. □

Counterexample 27.7.6.

1. $\sin(1/x)$ has no limit at 0: along $x_n = 1/(2\pi n + \pi/2)$ it is 1, along $y_n = 1/(\pi n)$ it is 0 ($n \geq 1$), and Theorem 27.3.4 applies. Since $x_n - y_n \to 0$, $\sin(1/x)$ is continuous but not uniformly continuous on $(0, 1)$. On the other hand $x \sin(1/x) \to 0$ by the squeeze theorem, as $|x \sin(1/x)| \leq |x|$.

2. A derivative need not be continuous. Let $f(x) = x^2 \sin(1/x)$ for $x \neq 0$ and $f(0) = 0$. Then $f'(0) = \lim_{x\to 0} x \sin(1/x) = 0$, and $f'(x) = 2x \sin(1/x) - \cos(1/x)$ for $x \neq 0$, which has no limit at 0. In accordance with Proposition 27.6.9 and Theorem 27.6.11, the discontinuity of f' at 0 is essential.

3. The converse of de l'Hôpital's rule fails. With f as in (2) and $g(x) = x$, $f(x)/g(x) = x \sin(1/x) \to 0$, while $f'(x)/g'(x) = 2x \sin(1/x) - \cos(1/x)$ has no limit as $x \to 0$.

Corollary 27.7.7 (Inequality of arithmetic and geometric means)**.** *For $x_1, \ldots, x_k > 0$ and weights $t_i \geq 0$ with $\sum t_i = 1$, $\prod_i x_i^{t_i} \leq \sum_i t_i x_i$. In particular $\sqrt[k]{x_1 \cdots x_k} \leq \frac{1}{k}(x_1 + \cdots + x_k)$, with equality if and only if all x_i are equal.*

Proof. $\log'' = -1/x^2 < 0$, so log is concave (Proposition 27.6.18(3)), and by Jensen's inequality $\sum t_i \log x_i \leq \log \sum t_i x_i$. Apply exp, which is increasing. For the equality statement, let $m = \frac{1}{k}\sum x_i$. As $\log'$ is strictly decreasing, the mean value theorem gives $\log x < \log m + (x - m)/m$ for every $x > 0$ with $x \neq m$ (the tangent inequality of Proposition 27.6.18(2) for $-\log$, made strict). Averaging over $x = x_1, \ldots, x_k$ gives $\frac{1}{k}\sum \log x_i < \log m$ unless all $x_i = m$. □

Lemma 27.7.8. *The function $\beta(t) = e^{-1/t}$ for $t > 0$ and $\beta(t) = 0$ for $t \leq 0$ has derivatives of all orders on $\mathbb{R}$, all vanishing at 0. The function $\gamma(t) = \beta(t)/(\beta(t) + \beta(1-t))$ has derivatives of all orders, takes values in $[0, 1]$, and equals 0 for $t \leq 0$ and 1 for $t \geq 1$.*

Proof. By induction, on $t > 0$, $\beta^{(k)}(t) = p_k(1/t)e^{-1/t}$ for a polynomial p_k. Since $e^s \geq s^m/m!$ for $s > 0$, $s^j e^{-s} \to 0$ as $s \to \infty$; so $\beta^{(k)}(t) \to 0$ as $t \to 0^+$, and the difference quotients of $\beta^{(k)}$ at 0 tend to 0, which by induction shows $\beta^{(k+1)}(0) = 0$. The denominator of γ never vanishes (one of t, $1 - t$ is positive), so γ has derivatives of all orders by Proposition 27.6.2, and the other properties are clear. □

Definition 27.7.9. A function $f : U \to \mathbb{R}$ on an open set $U \subseteq \mathbb{R}$ is *(real) analytic* if every $a \in U$ has a neighbourhood on which $f(x) = \sum_n c_n(x - a)^n$ for a convergent power series.

Proposition 27.7.10.

1. *If $f(x) = \sum_n a_n x^n$ has radius of convergence $R > 0$ and $|b| < R$, then $f(b + h) = \sum_k \frac{f^{(k)}(b)}{k!} h^k$ for $|h| < R - |b|$. So f is analytic on $(-R, R)$.*

2. *An analytic function is smooth, and near each point it equals its Taylor series there.*

3. *(Identity theorem) Let f be analytic on an open interval I. If all derivatives of f vanish at one point, or if the zeros of f have an accumulation point in I, then $f = 0$ on I.*

Proof. (1) $\sum_n \sum_{k\leq n} |a_n| \binom{n}{k} |b|^{n-k}|h|^k = \sum_n |a_n|(|b|+|h|)^n < \infty$, so the double series $\sum_{n,k} a_n \binom{n}{k} b^{n-k}h^k$ converges absolutely and may be summed in any order (Proposition 27.5.4(1)): summing over k first gives $f(b + h)$, and summing over n first gives $\sum_k c_k h^k$ with $c_k = \sum_{n\geq k} a_n \binom{n}{k} b^{n-k}$, which is $f^{(k)}(b)/k!$ by Theorem 27.6.20. (2) follows from Theorem 27.6.20 applied to the local expansions.

(3) Let S be the set of points of I where all derivatives of f vanish. It is closed in I, as the derivatives are continuous, and open: near $x \in S$, f equals its Taylor series at x, which is 0, so $f = 0$ near x. As I is connected (Theorem 18.5.3), $S = \emptyset$ or $S = I$. If the zeros accumulate at $a \in I$ and $f(x) = \sum c_n(x-a)^n$ near a with some $c_n \neq 0$, let m be least with $c_m \neq 0$; then $f(x) = (x-a)^m g(x)$ with g continuous and $g(a) = c_m \neq 0$, so f has no zeros near a other than a, a contradiction. So all derivatives vanish at a, and $S = I$. □

Polynomials, exp, sin and cos are analytic on $\mathbb{R}$, by (1), with radius ∞. The function $1/(1+x^2)$ is smooth on $\mathbb{R}$, but its Taylor series at 0, $\sum(-1)^n x^{2n}$, has radius only 1: the obstruction is invisible on $\mathbb{R}$, and comes from the complex points $\pm i$ where $1/(1+z^2)$ is not defined; it is nevertheless analytic on all of $\mathbb{R}$, as holomorphic functions are analytic (Chapter 29). The identity theorem fails for smooth functions:

Counterexample 27.7.11. The function β of Lemma 27.7.8 has all derivatives zero at 0, so its Taylor series at 0 is zero, but $\beta(t) \neq 0$ for $t > 0$. Smooth functions need not be given by their Taylor series; complex differentiable functions are (Chapter 29).

27.8 The Riemann integral

Definition 27.8.1. Let $f\colon [a,b] \to \mathbb{R}$ be bounded. For a partition $P\colon a = t_0 < \cdots < t_k = b$ let $U(f,P) = \sum_i (t_i - t_{i-1}) \sup_{[t_{i-1},t_i]} f$ and $L(f,P)$ the same with inf. The function is *Riemann integrable* if $\sup_P L(f,P) = \inf_P U(f,P)$, and this common value is $\int_a^b f = \int_a^b f(t)\,dt$. A $\mathbb{C}^m$-valued function is integrable if its real and imaginary components are, with the integral taken componentwise. We set $\int_b^a f = -\int_a^b f$.

Proposition 27.8.2.

1. *If P' refines P, then $L(f,P) \le L(f,P') \le U(f,P') \le U(f,P)$; and $L(f,P) \le U(f,Q)$ for all P, Q. So f is integrable if and only if for every $\varepsilon > 0$ there is P with $U(f,P) - L(f,P) < \varepsilon$.*

2. *Continuous functions are integrable, and $\sum_i (t_i - t_{i-1}) f(s_i) \to \int_a^b f$ for any choice of $s_i \in [t_{i-1}, t_i]$ as $\max_i (t_i - t_{i-1}) \to 0$.*

3. *For continuous f, g: the integral is linear, $f \le g$ implies $\int f \le \int g$, $\int_a^c f = \int_a^b f + \int_b^c f$, $|\int_a^b f| \le \int_a^b |f|$ for $\mathbb{C}^m$-valued f with the Euclidean norm, and if $f_n \to f$ uniformly, $\int f_n \to \int f$.*

Proof. (1) Adding a point to a partition can only increase infima and decrease suprema on the pieces; for P, Q compare both with $P \cup Q$. (2) By uniform continuity (Corollary 18.7.5), for $\varepsilon > 0$ there is δ such that f varies by less than ε on intervals of length $< \delta$; for partitions of mesh $< \delta$, $U - L \le \varepsilon(b-a)$, and Riemann sums lie between L and U. (3) Linearity and additivity follow from (2), monotonicity from $L(f,P) \le L(g,P)$, and uniform limits from $|\int (f_n - f)| \le (b-a) \sup |f_n - f|$. For the norm inequality let $v = \int f \in \mathbb{C}^m$; then $\|v\|^2 = \operatorname{Re}\langle \int f, v\rangle = \int \operatorname{Re}\langle f(t), v\rangle\,dt \le \int \|f\|\,\|v\|$ by Cauchy–Schwarz (Proposition 11.10.2). □

Theorem 27.8.3 (Fundamental theorem of calculus)**.** *Let $f\colon [a,b] \to \mathbb{C}^m$ be continuous. Then $F(x) = \int_a^x f$ is differentiable with $F' = f$. If $G\colon [a,b] \to \mathbb{C}^m$ is continuously differentiable, then $\int_a^b G' = G(b) - G(a)$.*

Proof. $|(F(x+h) - F(x))/h - f(x)| = |\frac{1}{h}\int_x^{x+h} (f - f(x))| \le \sup_{|t-x|\le|h|} |f(t) - f(x)| \to 0$. For the second statement, $\int_a^x G' - G(x)$ has derivative 0, hence is constant by Theorem 27.6.6 applied to real and imaginary components. □

Corollary 27.8.4. *For continuously differentiable f, g and $\varphi\colon [c,d] \to [a,b]$: $\int_a^b f'g = [fg]_a^b - \int_a^b fg'$ and $\int_c^d f(\varphi(s))\varphi'(s)\,ds = \int_{\varphi(c)}^{\varphi(d)} f$ for continuous f. Moreover $\|G(b) - G(a)\| \le (b-a)\sup\|G'\|$ for G continuously differentiable.*

Proof. Apply Theorem 27.8.3 to fg, to $F \circ \varphi$ with $F(x) = \int_a^x f$, and use the norm inequality of Proposition 27.8.2. □

The first formula of the corollary is *integration by parts*: it moves the derivative from one factor to the other, at the price of a boundary term. It is useful whenever differentiating one factor simplifies it while integrating the other does not make it worse.

Example 27.8.5.

1. With $f(x) = e^x$ and $g(x) = x$, so that $f'g = xe^x$: $\int_0^1 xe^x\,dx = [xe^x]_0^1 - \int_0^1 e^x\,dx = e - (e-1) = 1$.

2. With $f(x) = x$ and $g = \log$, so that $f'g = \log x$ and $fg' = 1$: $\int_1^e \log x\,dx = [x\log x]_1^e - \int_1^e 1\,dx = e - (e-1) = 1$.

3. *Wallis' integrals.* Let $I_n = \int_0^{\pi/2} \sin^n x\,dx$, so $I_0 = \frac{\pi}{2}$ and $I_1 = 1$. For $n \ge 2$ take $f(x) = -\cos x$ and $g(x) = \sin^{n-1} x$: the boundary term $[-\cos x \sin^{n-1} x]_0^{\pi/2}$ vanishes, and
$$I_n = (n-1)\int_0^{\pi/2} \cos^2 x \sin^{n-2} x\,dx = (n-1)(I_{n-2} - I_n), \qquad \text{so} \qquad I_n = \frac{n-1}{n} I_{n-2}.$$
Hence $I_{2m} = \frac{1\cdot 3\cdots(2m-1)}{2\cdot 4\cdots(2m)} \cdot \frac{\pi}{2}$ and $I_{2m+1} = \frac{2\cdot 4\cdots(2m)}{3\cdot 5\cdots(2m+1)}$.

4. *Periodic functions.* If f and g are continuously differentiable and 2π-periodic, the boundary term $[fg]_0^{2\pi}$ vanishes, and $\int_0^{2\pi} f'g = -\int_0^{2\pi} fg'$: without boundary, the derivative can be moved from one factor to the other at the cost of a sign. In several variables this becomes $\int (\partial_i f)g = -\int f\,\partial_i g$ for compactly supported functions (Chapter 28), and on a region with boundary the boundary term becomes an integral over the boundary (Green's identities, Chapter 40).

Proposition 27.8.6 (Mean value theorem for integrals)**.** *Let $f, g\colon [a,b] \to \mathbb{R}$ be continuous with $g \ge 0$. Then there is $c \in [a,b]$ with $\int_a^b fg = f(c)\int_a^b g$. In particular $\int_a^b f = f(c)(b-a)$ for some c: the average value of a continuous function is attained.*

Proof. Let m, M be the minimum and maximum of f (Corollary 18.6.6). Then $mg \le fg \le Mg$, so $m\int g \le \int fg \le M\int g$. If $\int g = 0$ any c works; otherwise $\int fg / \int g \in [m,M]$ is a value of f by the intermediate value theorem (Corollary 18.5.5). □

The hypotheses matter: for $g(x) = x$ on $[-1,1]$ and $f = g$, $\int fg = \frac{2}{3}$ while $\int g = 0$; and for vector-valued f the statement fails, since $f(t) = e^{it}$ on $[0, 2\pi]$ has integral 0 but never vanishes.

Example 27.8.7. *Computing integrals.* The fundamental theorem of calculus reduces integration to finding antiderivatives, and the rules of Corollary 27.8.4 are the main tools.

1. *Substitution.* With $u = 1 + x^2$, $du = 2x\,dx$: $\int_0^1 \frac{x}{1+x^2}\,dx = \frac{1}{2}\int_1^2 \frac{du}{u} = \frac{1}{2}\log 2$.

2. *Partial fractions.* $\frac{1}{x^2-1} = \frac{1}{2}\left(\frac{1}{x-1} - \frac{1}{x+1}\right)$, so $\int_2^3 \frac{dx}{x^2-1} = \frac{1}{2}\left[\log\frac{x-1}{x+1}\right]_2^3 = \frac{1}{2}\log\frac{3}{2}$. In general every rational function is a polynomial plus a combination of terms $(x-a)^{-k}$ and $(Ax+B)((x-p)^2+q^2)^{-k}$, whose antiderivatives involve only rational functions, log and arctan.

3. *Trigonometric substitution.* With $x = \sin\theta$: $\int_{-1}^{1} \sqrt{1-x^2}\,dx = \int_{-\pi/2}^{\pi/2} \cos^2\theta\,d\theta = \frac{\pi}{2}$, the area of a half disc; here $\cos^2\theta = \frac{1}{2}(1+\cos 2\theta)$.

4. *Symmetry.* $\int_{-a}^{a} f = 0$ for odd f, as the substitution $x \mapsto -x$ shows; for instance $\int_{-1}^{1} x^3 e^{x^2}\,dx = 0$ without computing an antiderivative.

5. *Recursion by parts*, as for Wallis' integrals in Example 27.8.5: $\int_0^1 x^n e^x\,dx = e - n\int_0^1 x^{n-1}e^x\,dx$.

Many integrals have no elementary antiderivative, such as $\int e^{-x^2}\,dx$; they are computed by other means, such as polar coordinates for $\int_{\mathbb{R}} e^{-x^2} = \sqrt{\pi}$ and differentiation with respect to a parameter (Chapter 28).

Theorem 27.8.8 (Stirling's formula)**.** *$n! \sim \sqrt{2\pi n}\,(n/e)^n$, that is, $n!\,e^n/(n^{n+1/2}\sqrt{2\pi}) \to 1$ as $n \to \infty$.*

Proof. Step 1: $a_n = n!\,e^n/n^{n+1/2}$ converges to some $C > 0$. For $t \geq 0$, $t - \frac{t^2}{2} \leq \log(1+t) \leq t - \frac{t^2}{2} + \frac{t^3}{3}$: the differences vanish at 0 and have derivatives $\frac{t^2}{1+t} \geq 0$ and $\frac{t^3}{1+t} \geq 0$. Now $\log(a_n/a_{n+1}) = (n+\frac{1}{2})\log(1+\frac{1}{n}) - 1$, and with $t = 1/n$ the two bounds give $-\frac{1}{4n^2} \leq \log(a_n/a_{n+1}) \leq \frac{1}{12n^2} + \frac{1}{6n^3} \leq \frac{1}{4n^2}$. So $\sum_n \log(a_n/a_{n+1})$ converges absolutely, $\log a_n$ converges, and $a_n \to C > 0$.

Step 2: $C = \sqrt{2\pi}$. With Wallis' integrals I_k (Example 27.8.5), $\sin^{2m+1} \leq \sin^{2m} \leq \sin^{2m-1}$ on $[0, \frac{\pi}{2}]$ gives $I_{2m+1} \leq I_{2m} \leq I_{2m-1} = \frac{2m+1}{2m} I_{2m+1}$, so $I_{2m}/I_{2m+1} \to 1$. Using $2\cdot 4\cdots 2m = 2^m m!$ and $1\cdot 3\cdots(2m-1) = (2m)!/(2^m m!)$, this says

$$\frac{\pi}{2} = \lim_{m\to\infty} \frac{2^{4m}(m!)^4}{((2m)!)^2(2m+1)}$$

(Wallis' product). Substituting $m! = a_m m^{m+1/2}e^{-m}$ and $(2m)! = a_{2m}(2m)^{2m+1/2}e^{-2m}$, the right side is $\frac{a_m^4}{a_{2m}^2}\cdot\frac{m}{2(2m+1)} \to \frac{C^2}{4}$. Hence $C^2 = 2\pi$. □

For example $10! = 3628800$, while $\sqrt{20\pi}(10/e)^{10} \approx 3598696$, an error of less than 1%; the relative error is about $1/(12n)$, in accordance with the bound in Step 1.

Proposition 27.8.9. *Let $f\colon [c,d]\times[a,b] \to \mathbb{C}$ be continuous.*

1. *$x \mapsto \int_a^b f(x,t)\,dt$ is continuous, and if $\partial_x f$ exists and is continuous on $[c,d]\times[a,b]$, it is differentiable with derivative $\int_a^b \partial_x f(x,t)\,dt$.*

2. *(Fubini for continuous functions) $\int_c^d \int_a^b f(x,t)\,dt\,dx = \int_a^b \int_c^d f(x,t)\,dx\,dt$.*

Proof. (1) Continuity follows from uniform continuity of f. For the derivative, by the mean value theorem applied to real and imaginary parts, $(f(x+h,t) - f(x,t))/h - \partial_x f(x,t)$ is bounded by the oscillation of $\partial_x f$ over $|s-x| \leq |h|$, which tends to 0 uniformly in t by uniform continuity. (2) Let $\Phi(y) = \int_c^y \int_a^b f\,dt\,dx$ and $\Psi(y) = \int_a^b \int_c^y f\,dx\,dt$. By Theorem 27.8.3 and (1) (applied to $g(y,t) = \int_c^y f(x,t)\,dx$, with $\partial_y g = f$ continuous), $\Phi' = \Psi' = \int_a^b f(y,t)\,dt$, and $\Phi(c) = \Psi(c) = 0$. □

27.9 Sequences of functions

Definition 27.9.1. Let D be a set and $f_n, f : D \to \mathbb{K}^m$. Then $f_n \to f$ *pointwise* if $f_n(x) \to f(x)$ for every $x \in D$, and *uniformly* if $\|f_n - f\|_\infty = \sup_{x\in D} \|f_n(x) - f(x)\| \to 0$.

The difference is the order of quantifiers: for pointwise convergence the threshold N may depend on x, for uniform convergence it may not. Uniform convergence implies pointwise convergence.

Proposition 27.9.2. *1. (Cauchy criterion) (f_n) converges uniformly on D if and only if for every $\varepsilon > 0$ there is N with $\|f_n - f_m\|_\infty < \varepsilon$ for $m, n \geq N$.*

2. If D is a metric space, the f_n are continuous and $f_n \to f$ uniformly, then f is continuous.

3. If $f_n \to f$ uniformly on $[a, b]$ and the f_n are continuous, then $\int_a^b f_n \to \int_a^b f$.

Proof. (1) If $f_n \to f$ uniformly, use the triangle inequality. Conversely, for each x the sequence $(f_n(x))$ is Cauchy, hence converges to some $f(x)$ (Theorem 27.2.13, componentwise). Letting $m \to \infty$ in $\|f_n(x) - f_m(x)\| < \varepsilon$ gives $\|f_n(x) - f(x)\| \leq \varepsilon$ for $n \geq N$ and all x. (2) is Proposition 18.3.10. (3) is Proposition 27.8.2(3). □

Counterexample 27.9.3. 1. $f_n(x) = x^n$ on $[0, 1]$ converges pointwise to the function equal to 0 on $[0, 1)$ and 1 at 1, which is discontinuous; so the convergence is not uniform. On $[0, 1)$ the limit 0 is continuous, but $\sup_{[0,1)} x^n = 1$, so the convergence is still not uniform. On $[0, r]$ with $r < 1$ it is uniform, as sup $= r^n \to 0$.

2. Pointwise convergence does not commute with integration. Let $f_n(x) = nx(1 - x^2)^n$ on $[0, 1]$. For $0 < x \leq 1$, $f_n(x) \to 0$ by Proposition 27.2.9(3) with $a = (1-x^2)^{-1}$ (or trivially if $x = 1$), and $f_n(0) = 0$. But, substituting $u = 1 - x^2$, $\int_0^1 f_n = \frac{n}{2} \int_0^1 u^n \, du = \frac{n}{2(n+1)} \to \frac{1}{2} \neq 0$.

3. Uniform convergence does not commute with differentiation. $f_n(x) = x^n/n$ converges uniformly to 0 on $[0, 1]$, since $|f_n| \leq 1/n$, but $f_n'(1) = 1$ for all n.

Theorem 27.9.4. *Let $f_n : [a, b] \to \mathbb{R}$ be continuously differentiable. Suppose that (f_n') converges uniformly to g and that $(f_n(x_0))$ converges for some $x_0 \in [a, b]$. Then (f_n) converges uniformly to a continuously differentiable f with $f' = g$.*

Proof. The function g is continuous by Proposition 27.9.2(2). Let $L = \lim f_n(x_0)$ and $f(x) = L + \int_{x_0}^x g$, which is continuously differentiable with $f' = g$ by Theorem 27.8.3. By the same theorem $f_n(x) = f_n(x_0) + \int_{x_0}^x f_n'$, so $|f_n(x) - f(x)| \leq |f_n(x_0) - L| + (b - a)\|f_n' - g\|_\infty$, which tends to 0 uniformly in x. □

Theorem 27.9.5 (Dini)**.** *Let K be a compact metric space and $f_n : K \to \mathbb{R}$ continuous functions with $f_1 \leq f_2 \leq \cdots$, converging pointwise to a continuous function f. Then the convergence is uniform.*

Proof. Let $g_n = f - f_n$, continuous, ≥ 0, decreasing in n and tending to 0 pointwise. For $\varepsilon > 0$ the sets $K_n = \{x : g_n(x) \geq \varepsilon\}$ are closed, decreasing, and have empty intersection. By compactness some K_N is empty (the complements form an open cover with a finite subcover, and the K_n decrease), and then $0 \leq g_n < \varepsilon$ on K for $n \geq N$. □

Counterexample 27.9.6. Each hypothesis of Dini's theorem is needed. On the noncompact $[0, 1)$, $f_n(x) = -x^n$ increases to the continuous function 0, not uniformly. On $[0, 1]$, $f_n(x) = -x^n$ increases to a discontinuous limit, not uniformly. And without monotonicity, the continuous functions $f_n(x) = \max(0, 1 - |nx - 2|)$, bumps of height 1 moving towards 0, converge pointwise to 0 on $[0, 1]$ but not uniformly.

Corollary 27.9.7 (Series of functions)**.** *Let $u_n\colon [a,b]\to\mathbb{R}$ be continuous and suppose $\sum_n \|u_n\|_\infty < \infty$. Then $\sum_n u_n$ converges uniformly to a continuous function, and $\int_a^b \sum_n u_n = \sum_n \int_a^b u_n$. If moreover the u_n are continuously differentiable and $\sum_n \|u_n'\|_\infty<\infty$, then $\sum_n u_n$ is continuously differentiable with derivative $\sum_n u_n'$.*

Proof. Apply the Weierstrass M-test (Proposition 27.5.4(5)) and Propositions 27.9.2(2),(3) to the partial sums, and Theorem 27.9.4 to the partial sums and their derivatives. □

Theorem 27.9.8 (A continuous nowhere differentiable function)**.** *Let $d(x)$ be the distance from $x\in\mathbb{R}$ to the nearest integer. The* Takagi function *$T(x)=\sum_{m\ge 0} 2^{-m} d(2^m x)$ is continuous on $\mathbb{R}$ and differentiable at no point.*

Proof. Since $0\le d\le \tfrac12$ and d is continuous (it is 1-Lipschitz), the series converges uniformly by the M-test, and T is continuous.

We first note: if f is differentiable at x and $u_n\le x\le v_n$ with $u_n<v_n$ and $v_n-u_n\to 0$, then $\frac{f(v_n)-f(u_n)}{v_n-u_n}\to f'(x)$. Indeed, with $\lambda_n=(v_n-x)/(v_n-u_n)\in[0,1]$,

$$\frac{f(v_n)-f(u_n)}{v_n-u_n}=\lambda_n\frac{f(v_n)-f(x)}{v_n-x}+(1-\lambda_n)\frac{f(x)-f(u_n)}{x-u_n},$$

where a term with weight 0 (when $v_n=x$ or $u_n=x$) is omitted; both quotients tend to $f'(x)$, and so does their convex combination.

Fix x, and for $n\ge 1$ let $u_n=k_n/2^n\le x<v_n=(k_n+1)/2^n$ with $k_n\in\mathbb{Z}$. For $m\ge n$, $2^m u_n$ and $2^m v_n$ are integers, so $d(2^m u_n)=d(2^m v_n)=0$. For $m<n$, the numbers $2^m u_n$ and $2^m v_n$ are consecutive multiples of $2^{m-n}\le\frac12$, so they lie in a common interval $[\frac{j}{2},\frac{j+1}{2}]$, on which d is affine with slope ±1. Hence

$$q_n=\frac{T(v_n)-T(u_n)}{v_n-u_n}=\sum_{m=0}^{n-1}2^{-m}\frac{d(2^m v_n)-d(2^m u_n)}{v_n-u_n}=\sum_{m=0}^{n-1}\varepsilon_{m,n},\qquad \varepsilon_{m,n}\in\{1,-1\}.$$

So q_n is an integer of the same parity as n, and (q_n) cannot converge: consecutive terms differ by an odd integer, so $|q_{n+1}-q_n|\ge 1$. By the preliminary remark, T is not differentiable at x. □

27.10 Derivatives in several variables

Lemma 27.10.1. *All norms on a finite-dimensional real or complex vector space are equivalent (they define the same topology), and every linear map $A\colon V\to W$ between finite-dimensional normed spaces is continuous, with finite* operator norm *$\|A\|=\sup_{\|v\|\le1}\|Av\|$. Then $\|Av\|\le\|A\|\,\|v\|$ and $\|AB\|\le\|A\|\,\|B\|$.*

Proof. Identify V with $\mathbb{R}^n$ by a basis and let $\|\cdot\|$ be a norm. By the triangle inequality and Cauchy–Schwarz, $\|x\|\le\sum|x_i|\,\|e_i\|\le C\|x\|_2$, so $\|\cdot\|$ is continuous for the Euclidean topology. On the compact unit sphere of $\|\cdot\|_2$ it attains a minimum $c>0$, so $c\|x\|_2\le\|x\|\le C\|x\|_2$, and Lemma 18.3.4 applies. A linear map is Lipschitz for Euclidean norms, since $\|Ax\|\le\sum|x_i|\,\|Ae_i\|$. The inequalities follow from the definition. □

Definition 27.10.2. Let $U\subseteq\mathbb{R}^n$ be open and $f\colon U\to\mathbb{R}^m$. Then f is *differentiable* at $a\in U$ if there is a linear map $Df(a)\colon\mathbb{R}^n\to\mathbb{R}^m$ with

$$f(a+h)=f(a)+Df(a)h+r(h),\qquad \|r(h)\|/\|h\|\to 0\text{ as }h\to 0.$$

The *partial derivatives* are $\partial_j f(a) = \frac{d}{dt} f(a + te_j)|_{t=0}$. The map f is C^1 if it is differentiable everywhere and $Df : U \to \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^m)$ is continuous; C^k if Df is C^{k-1}; and *smooth* (C^∞) if it is C^k for all k. A *C^k-diffeomorphism* is a bijection between open sets which is C^k with C^k inverse.

Proposition 27.10.3. *1. $Df(a)$ is unique, f is continuous at a, and the matrix of $Df(a)$ is the* Jacobian matrix $(\partial_j f_i(a))$.

2. *(Chain rule) If f is differentiable at a and g at $f(a)$, then $g \circ f$ is differentiable at a and $D(g \circ f)(a) = Dg(f(a)) \circ Df(a)$.*

3. *If all partial derivatives of f exist near a and are continuous at a, then f is differentiable at a. So f is C^1 if and only if its partial derivatives exist and are continuous, and C^k if and only if all partial derivatives of order at most k exist and are continuous.*

4. *(Mean value inequality) If f is C^1 and the segment $[x, y]$ lies in U, then $\|f(y) - f(x)\| \leq \sup_{z\in[x,y]} \|Df(z)\| \, \|y - x\|$.*

Proof. (1) If A and B both work, $\|(A - B)h\|/\|h\| \to 0$, so $A = B$ by linearity. Taking $h = te_j$ gives the partial derivatives. (2) Let $b = f(a)$, $k = f(a + h) - b = Df(a)h + r_f(h)$. Then $g(f(a + h)) - g(b) - Dg(b)Df(a)h = Dg(b)r_f(h) + r_g(k)$. For small h, $\|k\| \leq (\|Df(a)\| + 1)\|h\|$, so both terms are $o(\|h\|)$. (3) We may assume $m = 1$. Write $f(a + h) - f(a) = \sum_j [f(a + h_1e_1 + \cdots + h_je_j) - f(a + h_1e_1 + \cdots + h_{j-1}e_{j-1})]$. By the mean value theorem the j-th term is $h_j\partial_j f(\xi_j)$ with ξ_j within $\|h\|$ of a, and $\partial_j f(\xi_j) \to \partial_j f(a)$. The statement about C^k follows by induction. (4) Let $g(t) = f(x + t(y - x))$; by the chain rule $g'(t) = Df(x + t(y - x))(y - x)$, and Corollary 27.8.4 applies. □

Counterexample 27.10.4. Let $f(x, y) = xy/(x^2 + y^2)$ for $(x, y) \neq 0$ and $f(0) = 0$. Both partial derivatives exist everywhere (f vanishes on the axes), but $f(t, t) = 1/2$ for $t \neq 0$, so f is not continuous at 0, let alone differentiable.

Theorem 27.10.5 (Schwarz)**.** *If $f : U \to \mathbb{R}$ is C^2, then $\partial_i\partial_j f = \partial_j\partial_i f$.*

Proof. Restricting to the plane of the i-th and j-th coordinates, we may assume $n = 2$. For a rectangle $R = [x_0, x_1] \times [y_0, y_1] \subseteq U$, Theorem 27.8.3 applied twice gives $\int_{y_0}^{y_1} \int_{x_0}^{x_1} \partial_x\partial_y f \, dx \, dy = f(x_1, y_1) - f(x_0, y_1) - f(x_1, y_0) + f(x_0, y_0)$, and the same for $\int_{x_0}^{x_1} \int_{y_0}^{y_1} \partial_y\partial_x f \, dy \, dx$. By Proposition 27.8.9(2), the continuous function $g = \partial_x\partial_y f - \partial_y\partial_x f$ has integral 0 over every small rectangle. If $g(p) > 0$, then $g > g(p)/2$ on a small rectangle around p, and its integral is positive, a contradiction. □

Counterexample 27.10.6. For $f(x, y) = xy(x^2 - y^2)/(x^2 + y^2)$, $f(0) = 0$, one computes $\partial_x f(0, y) = -y$ and $\partial_y f(x, 0) = x$, so $\partial_y\partial_x f(0) = -1 \neq 1 = \partial_x\partial_y f(0)$. The second partial derivatives exist but are not continuous at 0.

Theorem 27.10.7 (Taylor's theorem in several variables)**.** *Let $f : U \to \mathbb{R}$ be C^{k+1} and $[a, a + h] \subseteq U$. With multi-index notation $\partial^\alpha = \partial_1^{\alpha_1} \cdots \partial_n^{\alpha_n}$, $h^\alpha = h_1^{\alpha_1} \cdots h_n^{\alpha_n}$ and $\alpha! = \alpha_1! \cdots \alpha_n!$, there is $\xi \in (a, a + h)$ with*

$$f(a + h) = \sum_{|\alpha|\leq k} \frac{\partial^\alpha f(a)}{\alpha!} h^\alpha + \sum_{|\alpha|=k+1} \frac{\partial^\alpha f(\xi)}{\alpha!} h^\alpha.$$

Proof. Apply Theorem 27.6.12 to $g(t) = f(a + th)$ on $[0, 1]$. By the chain rule and Theorem 27.10.5, $g^{(j)}(t) = \sum_{|\alpha|=j} \frac{j!}{\alpha!} \partial^\alpha f(a + th)h^\alpha$ (the multinomial formula). □

Corollary 27.10.8. *For $0 < r < R$ there is a smooth function $\mathbb{R}^n \to [0,1]$ equal to 1 on the closed ball of radius r and to 0 outside the open ball of radius R.*

Proof. Take $x \mapsto 1 - \gamma((\|x\|^2 - r^2)/(R^2 - r^2))$ with γ as in Lemma 27.7.8; it is smooth by the chain rule, since $\|x\|^2$ is a polynomial. □

27.11 Curves, arc length and line integrals

A curve in $\mathbb{R}^n$ can be studied through a parametrisation, a map $t \mapsto \gamma(t)$, but many of the quantities we care about belong to the path traced out and not to the particular way of running along it: its length, the mass of a wire bent along it, the work done by a force field along it. This section defines these quantities, computes them by integrals, and checks that they do not depend on the parametrisation. Two kinds of integrals appear. The integral of a function with respect to arc length, $\int_\gamma f\, ds$, does not see the direction of travel; the integral of a vector field, $\int_\gamma F \cdot d\gamma$, does, and changes sign when the curve is run backwards. Traditionally they are called line integrals of the first and of the second kind. The first is the special case $f = 1$ of a mass, the second the special case of a 1-form; both reappear on manifolds (Chapters 36 and 40). Throughout, $|x|$ is the Euclidean norm on $\mathbb{R}^n$ and $\langle x, y\rangle = x \cdot y$ the standard inner product.

27.11.1 Curves and their length

Definition 27.11.1. A *curve* in $\mathbb{R}^n$ is a continuous map $\gamma\colon [a,b] \to \mathbb{R}^n$, with $a < b$; $\gamma(a)$ and $\gamma(b)$ are its *initial* and *final points*, and it is *closed* if they agree. It is of class C^1 if it is differentiable with continuous derivative $\gamma' = (\gamma_1', \dots, \gamma_n')$, one-sided at the ends, and *piecewise* C^1 if there is a subdivision $a = c_0 < c_1 < \cdots < c_m = b$ such that each restriction $\gamma|_{[c_{k-1},c_k]}$ is C^1. A C^1 curve is *regular* if $\gamma'(t) \neq 0$ for all t; then $\gamma'(t)$ is its *velocity* or tangent vector at t and $|\gamma'(t)|$ its *speed*.

A *reparametrisation* of γ is $\gamma \circ \varphi$, where $\varphi\colon [c,d] \to [a,b]$ is a continuous bijection. Such a φ is strictly monotone; it *preserves the orientation* if it is increasing, so that $\gamma \circ \varphi$ runs from $\gamma(a)$ to $\gamma(b)$, and *reverses* it if it is decreasing. The *reverse* of γ is $\gamma^-(t) = \gamma(a+b-t)$. For C^1 curves we use C^1 reparametrisations with φ' nowhere zero; by the chain rule $(\gamma\circ\varphi)'(s) = \varphi'(s)\,\gamma'(\varphi(s))$, so the velocity is rescaled but keeps its direction (up to sign). For instance $\gamma(t) = (\cos t, \sin t)$, $t \in [0, 2\pi]$, and $\tilde\gamma(s) = (\cos 2\pi s^2, \sin 2\pi s^2)$, $s \in [0,1]$, run once around the unit circle at different speeds, and γ^- runs around it clockwise.

How long is a curve? The ancient answer, used by Archimedes for the circle, is to approximate it by inscribed polygons. A polygon through points of the curve is shorter than the curve, because the segment is the shortest path between two points, and refining the polygon can only make it longer, by the triangle inequality. So the length should be the supremum of the lengths of the inscribed polygons.

Definition 27.11.2. For a curve $\gamma\colon [a,b] \to \mathbb{R}^n$ and a partition $P\colon a = t_0 < t_1 < \cdots < t_k = b$, let $\ell(\gamma, P) = \sum_{i=1}^k |\gamma(t_i) - \gamma(t_{i-1})|$ be the length of the inscribed polygon. The *length* of γ is

$$L(\gamma) = \sup_P \ell(\gamma, P) \in [0, \infty],$$

and γ is *rectifiable* if $L(\gamma) < \infty$.

Lemma 27.11.3. *Let $\gamma\colon [a,b] \to \mathbb{R}^n$ be a curve.*

1. *If P' refines P, then $\ell(\gamma, P) \le \ell(\gamma, P')$, and $|\gamma(b) - \gamma(a)| \le L(\gamma)$.*

2. (Additivity) *For $a < c < b$, $L(\gamma) = L(\gamma|_{[a,c]}) + L(\gamma|_{[c,b]})$.*

3. (Invariance) *$L(\gamma \circ \varphi) = L(\gamma)$ for every reparametrisation, of either orientation; in particular $L(\gamma^-) = L(\gamma)$.*

Proof. (1) Adding a point s between t_{i-1} and t_i replaces $|\gamma(t_i) - \gamma(t_{i-1})|$ by $|\gamma(s) - \gamma(t_{i-1})| + |\gamma(t_i) - \gamma(s)|$, which is at least as large by the triangle inequality; refining adds finitely many points. The trivial partition gives $|\gamma(b) - \gamma(a)| = \ell(\gamma, \{a, b\}) \le L(\gamma)$.

(2) A partition of $[a, c]$ and one of $[c, b]$ together form a partition of $[a, b]$, so $L(\gamma|_{[a,c]}) + L(\gamma|_{[c,b]}) \le L(\gamma)$, taking suprema over the two partitions separately. Conversely, for a partition P of $[a, b]$ let $P' = P \cup \{c\}$; then by (1) $\ell(\gamma, P) \le \ell(\gamma, P')$, and $\ell(\gamma, P')$ is the sum of the polygon lengths of the two restrictions, which is at most $L(\gamma|_{[a,c]}) + L(\gamma|_{[c,b]})$.

(3) A strictly monotone bijection $\varphi\colon [c, d] \to [a, b]$ maps partitions of $[c, d]$ bijectively to partitions of $[a, b]$ (reversing their order if φ decreases), and the inscribed polygons of $\gamma \circ \varphi$ and of γ for corresponding partitions have the same vertices, hence the same length. □

For a C^1 curve the supremum is an integral: the length is the integral of the speed, as the distance travelled by a car is the integral of the reading of its speedometer.

Theorem 27.11.4 (Length of a C^1 curve)**.** *Every piecewise C^1 curve is rectifiable, and*

$$L(\gamma) = \int_a^b |\gamma'(t)|\, dt,$$

the integral being the sum of the integrals over the pieces where γ is C^1.

Proof. By the additivity of Lemma 27.11.3(2) and of the integral, it suffices to treat a C^1 curve. The function $|\gamma'|$ is continuous, hence integrable. For any partition, the fundamental theorem of calculus (Theorem 27.8.3) and the norm inequality of Proposition 27.8.2(3) give

$$|\gamma(t_i) - \gamma(t_{i-1})| = \left| \int_{t_{i-1}}^{t_i} \gamma'(t)\, dt \right| \le \int_{t_{i-1}}^{t_i} |\gamma'(t)|\, dt,$$

and summing, $\ell(\gamma, P) \le \int_a^b |\gamma'|$. So $L(\gamma) \le \int_a^b |\gamma'|$.

For the converse inequality let $\varepsilon > 0$. Since γ' is uniformly continuous on $[a, b]$ (Corollary 18.7.5), there is $\delta > 0$ with $|\gamma'(s) - \gamma'(t)| < \varepsilon$ whenever $|s - t| < \delta$. Take a partition with $t_i - t_{i-1} < \delta$ for all i, and write $\Delta_i = t_i - t_{i-1}$. On $[t_{i-1}, t_i]$,

$$\gamma(t_i) - \gamma(t_{i-1}) = \int_{t_{i-1}}^{t_i} \gamma'(t)\, dt = \Delta_i\, \gamma'(t_i) + \int_{t_{i-1}}^{t_i} \big(\gamma'(t) - \gamma'(t_i)\big)\, dt,$$

and the last integral has norm at most $\varepsilon\Delta_i$. Hence $|\gamma(t_i) - \gamma(t_{i-1})| \ge \Delta_i |\gamma'(t_i)| - \varepsilon\Delta_i$. On the other hand $|\gamma'(t)| \le |\gamma'(t_i)| + \varepsilon$ on the interval, so $\int_{t_{i-1}}^{t_i} |\gamma'| \le \Delta_i |\gamma'(t_i)| + \varepsilon\Delta_i$. Combining and summing over i,

$$L(\gamma) \ge \ell(\gamma, P) \ge \int_a^b |\gamma'(t)|\, dt - 2\varepsilon(b - a).$$

As ε is arbitrary, $L(\gamma) \ge \int_a^b |\gamma'|$. □

In coordinates, $L(\gamma) = \int_a^b \sqrt{\gamma_1'(t)^2 + \cdots + \gamma_n'(t)^2}\, dt$. That this integral does not depend on the parametrisation, which is clear for the definition by polygons, can also be seen by the substitution rule: for φ increasing, $\int_c^d |\gamma'(\varphi(s))|\, \varphi'(s)\, ds = \int_a^b |\gamma'(t)|\, dt$ (Corollary 27.8.4), and for φ decreasing the absolute value $|\varphi'| = -\varphi'$ compensates the reversal of the limits.

Example 27.11.5. 1. *Circles.* For $\gamma(t) = (r\cos t, r\sin t)$, $t \in [0, 2\pi]$, $\gamma'(t) = (-r\sin t, r\cos t)$ has norm r, so $L(\gamma) = 2\pi r$. With the definition of π in Theorem 27.7.3, this is the theorem that the circumference of a circle is 2π times its radius.

2. *Graphs.* The graph of a C^1 function $f\colon [a,b] \to \mathbb{R}$, parametrised by $\gamma(x) = (x, f(x))$, has length $\int_a^b \sqrt{1 + f'(x)^2}\,dx$. For a line $f(x) = mx$ this is $(b-a)\sqrt{1+m^2}$, the length of the segment, by Pythagoras.

3. *The helix.* $\gamma(t) = (r\cos t, r\sin t, ct)$ has constant speed $\sqrt{r^2+c^2}$, so one turn has length $2\pi\sqrt{r^2+c^2}$: unrolling the cylinder of radius r into a plane turns the helix into the diagonal of a rectangle with sides $2\pi r$ and $2\pi c$.

4. *The cycloid.* A point on a rolling wheel of radius 1 traces $\gamma(t) = (t - \sin t, 1 - \cos t)$. Here $|\gamma'(t)|^2 = (1-\cos t)^2 + \sin^2 t = 2 - 2\cos t = 4\sin^2(t/2)$, so one arch has length $\int_0^{2\pi} 2\sin(t/2)\,dt = 8$, four times the diameter of the wheel (Wren, 1658). The curve is not regular: the speed vanishes at $t = 0$ and $t = 2\pi$, where the cycloid has cusps.

Remark 27.11.6. The length of an ellipse $(a\cos t, b\sin t)$ with $0 < b < a$ is $\int_0^{2\pi} \sqrt{a^2\sin^2 t + b^2\cos^2 t}\,dt = 4a\int_0^{\pi/2} \sqrt{1 - e^2\cos^2 t}\,dt$, with eccentricity $e = \sqrt{1 - b^2/a^2}$. Unlike the circle, this integral cannot be expressed by elementary functions. It is an *elliptic integral*, and the attempt to understand such integrals, by Euler, Legendre, Abel and Jacobi, led to elliptic functions and to elliptic curves: inverting the integral gives doubly periodic functions, and the natural domain of the integrand is a curve of genus one (Chapter 59).

Continuity alone does not give a finite length.

Counterexample 27.11.7. Let $f(x) = x\cos(\pi/x)$ for $0 < x \le 1$ and $f(0) = 0$; it is continuous, since $|f(x)| \le x$, and C^1 on $(0,1]$. At $x_m = 1/m$, $f(x_m) = (-1)^m/m$. Take the partition of $[0,1]$ by 0 and the points x_m, $m \le N$; consecutive values have opposite signs, so the inscribed polygon of the graph $\gamma(x) = (x, f(x))$ has length at least

$$\sum_{m=1}^{N-1} |f(x_m) - f(x_{m+1})| = \sum_{m=1}^{N-1} \Big(\frac{1}{m} + \frac{1}{m+1}\Big) \ge \sum_{m=1}^{N-1} \frac{1}{m},$$

which tends to ∞ with N (Proposition 27.5.5(1)). So γ is a continuous curve of infinite length: it oscillates too much near 0. Worse examples exist: the Koch snowflake curve has infinite length between any two of its points, and the space-filling curves of Chapter 18 fill a square.

For a regular curve the length can be used as a parameter. This removes the arbitrariness of the parametrisation and is the starting point of the differential geometry of curves.

Proposition 27.11.8 (Arc length parametrisation)**.** *Let $\gamma\colon [a,b] \to \mathbb{R}^n$ be a regular C^1 curve of length L, and $\sigma(t) = \int_a^t |\gamma'(u)|\,du$ the length of $\gamma|_{[a,t]}$. Then $\sigma\colon [a,b] \to [0,L]$ is a C^1 bijection with $\sigma' = |\gamma'| > 0$, its inverse is C^1, and $\tilde\gamma = \gamma\circ\sigma^{-1}\colon [0,L] \to \mathbb{R}^n$ has $|\tilde\gamma'(s)| = 1$ for all s. It is the unique orientation-preserving reparametrisation of γ with unit speed.*

Proof. By the fundamental theorem of calculus σ is C^1 with $\sigma'(t) = |\gamma'(t)| > 0$, so it is strictly increasing, with $\sigma(a) = 0$ and $\sigma(b) = L$ by Theorem 27.11.4. By Proposition 27.6.8 its inverse is differentiable with $(\sigma^{-1})'(s) = 1/|\gamma'(\sigma^{-1}(s))|$, which is continuous. By the chain rule $|\tilde\gamma'(s)| = |\gamma'(\sigma^{-1}(s))|\,(\sigma^{-1})'(s) = 1$. If $\gamma\circ\varphi$ is another orientation-preserving C^1 reparametrisation with unit speed, defined on $[c,d]$, then $1 = |\gamma'(\varphi(u))|\varphi'(u) = (\sigma\circ\varphi)'(u)$, so $\sigma(\varphi(u)) = u - c$, and $\gamma\circ\varphi$ is $\tilde\gamma$ up to the translation $u \mapsto u - c$ of the parameter. □

The parameter s of $\tilde\gamma$ is the *arc length*, and one writes $ds = |\gamma'(t)|\,dt$ for the *element of arc length*: it is the length of the piece of curve swept out between t and $t + dt$, to first order.

27.11.2 Line integrals of the first kind

Imagine a wire bent along a curve, with a linear density of mass f, in grams per centimetre. Its mass is obtained by cutting it into short pieces, multiplying the density at a point of each piece by the length of the piece, and adding up; in the limit this is an integral with respect to arc length.

Definition 27.11.9. Let $\gamma\colon [a,b] \to \mathbb{R}^n$ be a piecewise C^1 curve and f a continuous real function on its image $\gamma([a,b])$. The *line integral of f with respect to arc length*, or *of the first kind*, is

$$\int_\gamma f\,ds = \int_a^b f(\gamma(t))\,|\gamma'(t)|\,dt,$$

the sum of the integrals over the pieces where γ is C^1.

Proposition 27.11.10. *Let γ and f be as in the definition.*

1. $\int_\gamma 1\,ds = L(\gamma)$.
2. *The integral is linear in f, monotone ($f \le g$ implies $\int_\gamma f\,ds \le \int_\gamma g\,ds$), and $\left|\int_\gamma f\,ds\right| \le \sup|f| \cdot L(\gamma)$.*
3. *It is unchanged under every C^1 reparametrisation $\gamma\circ\varphi$ with φ' nowhere zero, of either orientation; in particular $\int_{\gamma^-} f\,ds = \int_\gamma f\,ds$.*
4. *It is additive: if γ is the concatenation of $\gamma|_{[a,c]}$ and $\gamma|_{[c,b]}$, the integral is the sum of the two integrals.*
5. *(*Riemann sums*)* $\sum_i f(\gamma(t_i))\,|\gamma(t_i)-\gamma(t_{i-1})| \to \int_\gamma f\,ds$ *as the mesh* $\max_i(t_i - t_{i-1})$ *of the partition tends to* 0.

Proof. (1) is Theorem 27.11.4, and (2) and (4) follow from the corresponding properties of the integral (Proposition 27.8.2). (3) For each C^1 piece and φ increasing, the substitution rule (Corollary 27.8.4) gives $\int_c^d f(\gamma(\varphi(u)))|\gamma'(\varphi(u))|\varphi'(u)\,du = \int_a^b f(\gamma(t))|\gamma'(t)|\,dt$, and $|(\gamma\circ\varphi)'| = |\gamma'\circ\varphi|\,\varphi'$. For φ decreasing, $|(\gamma\circ\varphi)'| = -|\gamma'\circ\varphi|\,\varphi'$, and the substitution reverses the limits, so the two signs cancel.

(5) It suffices to treat a C^1 curve. The proof of Theorem 27.11.4 shows that for partitions of mesh $< \delta$, $\big||\gamma(t_i)-\gamma(t_{i-1})| - \int_{t_{i-1}}^{t_i}|\gamma'|\big| \le 2\varepsilon\Delta_i$. Also $f\circ\gamma$ is uniformly continuous, so for small mesh it varies by less than ε on each interval. Hence the Riemann sum differs from $\sum_i \int_{t_{i-1}}^{t_i} f(\gamma(t))|\gamma'(t)|\,dt = \int_\gamma f\,ds$ by at most $\sup|f|\cdot 2\varepsilon(b-a) + \varepsilon L(\gamma)$. □

By (3), the integral of the first kind depends only on the curve traced out, not on the direction or the speed of travel, as the mass of a wire should. The *centre of mass* of a wire of density $f > 0$ is the point with coordinates $\bar{x}_j = \int_\gamma x_j f\,ds \big/ \int_\gamma f\,ds$.

Example 27.11.11.

1. The upper half of the circle of radius r, $\gamma(t) = (r\cos t, r\sin t)$, $t\in[0,\pi]$, with constant density 1, has mass πr and $\int_\gamma y\,ds = \int_0^\pi r\sin t\cdot r\,dt = 2r^2$. So its centre of mass is $(0, 2r/\pi)$, inside the half disc and not on the wire.
2. For the helix of Example 27.11.5(3) over one turn, $\int_\gamma z\,ds = \int_0^{2\pi} ct\sqrt{r^2+c^2}\,dt = 2\pi^2 c\sqrt{r^2+c^2}$, and the centre of mass is at height πc, half way up, as symmetry suggests.

27.11.3 Line integrals of the second kind

Now let a force field F act on a particle moving along a curve. The work done by the force on a short displacement Δx is $F \cdot \Delta x$: only the component of the force along the displacement counts. Adding up along the curve gives an integral that depends on the direction of travel: going backwards, every displacement changes sign.

Definition 27.11.12. Let $\gamma\colon [a,b] \to \mathbb{R}^n$ be a piecewise C^1 curve and $F = (F_1, \dots, F_n)$ a continuous vector field on its image. The *line integral of F along γ*, or *of the second kind*, is

$$\int_\gamma F \cdot d\gamma = \int_a^b \big\langle F(\gamma(t)), \gamma'(t) \big\rangle \, dt = \int_a^b \sum_{j=1}^{n} F_j(\gamma(t))\, \gamma_j'(t)\, dt,$$

also written $\int_\gamma F_1\, dx_1 + \cdots + F_n\, dx_n$; in the plane, $\int_\gamma P\, dx + Q\, dy$ for $F = (P, Q)$.

The notation $F_1\, dx_1 + \cdots + F_n\, dx_n$ is a differential form (Chapter 36): the rule is to substitute $x_j = \gamma_j(t)$ and $dx_j = \gamma_j'(t)\, dt$.

Proposition 27.11.13. *Let γ and F be as in the definition.*

1. *The integral is linear in F and additive under concatenation.*
2. *It is unchanged under orientation-preserving C^1 reparametrisations and changes sign under orientation-reversing ones: $\int_{\gamma^-} F \cdot d\gamma^- = -\int_\gamma F \cdot d\gamma$.*
3. *If γ is regular, with unit tangent $T = \gamma'/|\gamma'|$, then $\int_\gamma F \cdot d\gamma = \int_\gamma \langle F, T\rangle\, ds$: the integral of the second kind is the integral of the first kind of the tangential component of F.*
4. *$\left|\int_\gamma F \cdot d\gamma\right| \le \sup |F| \cdot L(\gamma)$.*
5. *(*Fundamental theorem for line integrals*) If $F = \nabla g$ is the gradient of a C^1 function g on an open set containing the image of γ, then $\int_\gamma \nabla g \cdot d\gamma = g(\gamma(b)) - g(\gamma(a))$. In particular the integral over a closed curve is 0.*

Proof. (1) follows from the properties of the integral. (2) On a C^1 piece, with $(\gamma \circ \varphi)'(u) = \varphi'(u)\gamma'(\varphi(u))$, the substitution rule gives $\int_c^d \langle F(\gamma(\varphi(u))), \gamma'(\varphi(u))\rangle \varphi'(u)\, du = \int_{\varphi(c)}^{\varphi(d)} \langle F(\gamma(t)), \gamma'(t)\rangle\, dt$, which is the original integral if φ increases and its negative if φ decreases. (3) $\langle F(\gamma(t)), \gamma'(t)\rangle = \langle F(\gamma(t)), T(t)\rangle |\gamma'(t)|$. (4) By Cauchy–Schwarz, $|\langle F(\gamma(t)), \gamma'(t)\rangle| \le \sup|F|\,|\gamma'(t)|$; integrate and use Theorem 27.11.4. (5) On a C^1 piece, by the chain rule (Proposition 27.10.3), $(g\circ\gamma)'(t) = \langle \nabla g(\gamma(t)), \gamma'(t)\rangle$, so the integral is $\int (g\circ\gamma)' = g(\gamma(c_k)) - g(\gamma(c_{k-1}))$ by Theorem 27.8.3; the intermediate values cancel in the sum. □

A vector field that is a gradient, $F = \nabla g$, is called *conservative*, and $-g$ (in physics) its *potential*: the work done along a path depends only on its endpoints. Not every field is of this kind.

Example 27.11.14. 1. *Rotation.* For $F(x,y) = (-y, x)$ and the circle $\gamma(t) = (r\cos t, r\sin t)$, $t \in [0, 2\pi]$, $\langle F(\gamma(t)), \gamma'(t)\rangle = r^2\sin^2 t + r^2\cos^2 t = r^2$, so $\int_\gamma F \cdot d\gamma = 2\pi r^2$, twice the area enclosed; this is no accident (Green's theorem, Chapter 40). The integral over a closed curve is not 0, so F is not a gradient.

2. *Dependence on the path.* For $F(x,y) = (y,0)$, that is $\int y\,dx$, from $(0,0)$ to $(1,1)$: along the segment $\gamma_1(t) = (t,t)$ the integral is $\int_0^1 t\,dt = \frac{1}{2}$; along the parabola $\gamma_2(t) = (t,t^2)$ it is $\int_0^1 t^2\,dt = \frac{1}{3}$; along the path that goes first to $(1,0)$ and then up to $(1,1)$ it is $0+0=0$, since $y=0$ on the first piece and $dx = 0$ on the second.

3. *A gradient.* For $F = \nabla g$ with $g(x,y) = x^2y$, $F = (2xy, x^2)$, and every path from $(0,0)$ to $(1,1)$ gives $g(1,1) - g(0,0) = 1$. Along γ_2, for instance, $\int_0^1 (2t\cdot t^2 + t^2\cdot 2t)\,dt = \int_0^1 4t^3\,dt = 1$.

4. *The angle field.* $F(x,y) = (-y,x)/(x^2+y^2)$ on $\mathbb{R}^2 \setminus \{0\}$ has integral 2π around the unit circle, so it is not a gradient on $\mathbb{R}^2 \setminus \{0\}$, although it is the gradient of the polar angle on every half-plane through the origin. This field, the 1-form $(x\,dy - y\,dx)/(x^2+y^2)$, is the simplest example of a closed form that is not exact, and the beginning of de Rham cohomology (Chapter 37).

Remark 27.11.15. The two kinds of line integrals answer different questions and behave differently. The first kind integrates a *density*, needs the Euclidean length to define ds, and ignores orientation; it generalises to integrals over curves in a Riemannian manifold (Chapter 40) and, in higher dimensions, to surface integrals $\int_\Sigma f\,dA$. The second kind integrates a 1-*form*, needs no metric at all, since $F_1\,dx_1 + \cdots + F_n\,dx_n$ is evaluated on velocity vectors, and depends on the orientation; it generalises to the integrals of k-forms over oriented k-dimensional submanifolds, and Stokes' theorem lives there (Chapter 36). Complex line integrals $\int_\gamma f(z)\,dz = \int_a^b f(\gamma(t))\gamma'(t)\,dt$, defined in Chapter 29 by this formula, the complex-valued integrand being integrated separately in its real and imaginary parts, are of the second kind, with complex coefficients: expanding $f\,dz = (u+iv)(dx + i\,dy)$ gives $\int_\gamma f\,dz = \int_\gamma (u\,dx - v\,dy) + i\int_\gamma (v\,dx + u\,dy)$, two real line integrals of the second kind. The relation $\int_\gamma F\cdot d\gamma = \int_\gamma \langle F, T\rangle\,ds$ shows that the second kind is a special case of the first, once a direction has been chosen; conversely $\int_\gamma f\,ds = \int_\gamma fT\cdot d\gamma$ for a regular curve. In Italian the two are the *integrali curvilinei di prima e di seconda specie*.

27.12 The inverse and implicit function theorems

Lemma 27.12.1. *If $A \in \mathrm{End}(\mathbb{R}^n)$ has $\|A\| < 1$, then $1 - A$ is invertible with inverse $\sum_k A^k$ and $\|(1-A)^{-1}\| \le 1/(1-\|A\|)$. The group $\mathrm{GL}_n(\mathbb{R})$ is open in $M_n(\mathbb{R})$, and inversion $\mathrm{GL}_n(\mathbb{R}) \to \mathrm{GL}_n(\mathbb{R})$ is smooth.*

Proof. The series converges absolutely in the complete space $M_n(\mathbb{R})$ (Proposition 27.5.4), and $(1-A)\sum_{k\le N} A^k = 1 - A^{N+1} \to 1$. The determinant is a polynomial in the entries, hence continuous, and $\mathrm{GL}_n(\mathbb{R}) = \det^{-1}(\mathbb{R}\setminus\{0\})$. By the adjugate formula (Proposition 11.5.3), the entries of A^{-1} are polynomials in the entries of A divided by $\det A$, so inversion is smooth. □

Theorem 27.12.2 (Inverse function theorem)**.** *Let $U \subseteq \mathbb{R}^n$ be open, $f : U \to \mathbb{R}^n$ of class C^k with $k \ge 1$, and $a \in U$ with $Df(a)$ invertible. There are open sets $V \ni a$ and $W \ni f(a)$ such that $f : V \to W$ is a C^k-diffeomorphism, and $D(f^{-1})(f(x)) = Df(x)^{-1}$.*

Proof. Replacing f by $x \mapsto Df(a)^{-1}(f(a+x) - f(a))$, we may assume $a = 0$, $f(0) = 0$ and $Df(0) = 1$. Let $g(x) = x - f(x)$, so $Dg(0) = 0$; choose $r > 0$ with $\overline{B}(0,r) \subseteq U$ and $\|Dg(x)\| \le 1/2$ there. By the mean value inequality, $\|g(x) - g(x')\| \le \frac{1}{2}\|x - x'\|$ on $\overline{B}(0,r)$, and $\|g(x)\| \le r/2$.

For $y \in W = B(0, r/2)$, the map $T_y(x) = y + g(x)$ sends $\overline{B}(0,r)$ into $B(0,r)$ and is a contraction with constant $1/2$. By the Banach fixed point theorem (Theorem 18.7.6) there is a

unique $x \in \overline{B}(0,r)$ with $x = y+g(x)$, that is, $f(x) = y$, and $x \in B(0,r)$. Let $V = B(0,r) \cap f^{-1}(W)$, open; then $f\colon V \to W$ is bijective. From $x - x' = f(x) - f(x') + g(x) - g(x')$ we get $\|x - x'\| \le 2\|f(x) - f(x')\|$, so f^{-1} is continuous. For $x \in V$, $Df(x) = 1 - Dg(x)$ is invertible with $\|Df(x)^{-1}\| \le 2$ (Lemma 27.12.1).

Let $y = f(x)$ and $y + \kappa = f(x+h)$ with $x, x+h \in V$, so $\|h\| \le 2\|\kappa\|$. Then $f^{-1}(y + \kappa) - f^{-1}(y) - Df(x)^{-1}\kappa = -Df(x)^{-1}(f(x+h) - f(x) - Df(x)h)$, whose norm is at most $2\|r(h)\| = o(\|\kappa\|)$. So f^{-1} is differentiable with $D(f^{-1}) = \iota \circ Df \circ f^{-1}$, where ι is inversion. If f^{-1} is C^j with $j < k$, this composite is C^j, so f^{-1} is C^{j+1}; by induction f^{-1} is C^k (composites of C^j maps are C^j by the chain rule and induction). □

Theorem 27.12.3 (Implicit function theorem)**.** *Let $U \subseteq \mathbb{R}^n \times \mathbb{R}^m$ be open, $F\colon U \to \mathbb{R}^m$ of class C^k, $(a,b) \in U$ with $F(a,b) = 0$, and suppose the partial derivative $D_y F(a,b)\colon \mathbb{R}^m \to \mathbb{R}^m$ is invertible. There are open sets $A \ni a$ and $B \ni b$ and a C^k map $g\colon A \to B$ such that for $(x,y) \in A \times B$: $F(x,y) = 0$ if and only if $y = g(x)$.*

Proof. The map $\Phi(x,y) = (x, F(x,y))$ has invertible derivative at (a,b), so by Theorem 27.12.2 it restricts to a C^k-diffeomorphism of an open set, which we may shrink to $A' \times B$, onto an open set containing $(a,0)$. Its inverse has the form $(x,z) \mapsto (x, \psi(x,z))$. Let $A = \{x : (x,0) \in \Phi(A' \times B)\}$, open, and $g(x) = \psi(x,0)$. □

Theorem 27.12.4 (Local submersions and immersions)**.** *Let $f\colon U \to \mathbb{R}^m$ be C^k, $U \subseteq \mathbb{R}^n$ open, $a \in U$.*

1. *If $Df(a)$ is surjective, there is a C^k-diffeomorphism ψ from a neighbourhood of a onto an open subset of $\mathbb{R}^n$ with $f \circ \psi^{-1}(x_1, \dots, x_n) = (x_1, \dots, x_m)$.*

2. *If $Df(a)$ is injective, there is a C^k-diffeomorphism ϕ from a neighbourhood of $f(a)$ onto an open subset of $\mathbb{R}^m$ with $\phi \circ f(x) = (x_1, \dots, x_n, 0, \dots, 0)$ near a.*

Proof. We may assume $a = 0$ and $f(0) = 0$. (1) After permuting coordinates, the first m columns of the Jacobian are linearly independent. Then $\psi(x) = (f(x), x_{m+1}, \dots, x_n)$ has invertible derivative at 0, and $f \circ \psi^{-1}$ is the projection. (2) After permuting target coordinates, the first n rows of the Jacobian are independent. Let $\Theta(x,y) = f(x) + (0,y)$ for $x \in U$, $y \in \mathbb{R}^{m-n}$; $D\Theta(0)$ is invertible, and $\phi = \Theta^{-1}$ satisfies $\phi(f(x)) = (x,0)$. □

Remark 27.12.5. More generally, if Df has constant rank r near a, there are local diffeomorphisms in source and target in which f becomes $(x_1, \dots, x_n) \mapsto (x_1, \dots, x_r, 0, \dots, 0)$ (the *constant rank theorem* [Lee13, Theorem 4.12]). All results of this section hold with the same proofs over $\mathbb{C}$ for complex differentiable (holomorphic) maps, once holomorphic functions are known to be C^∞ (Chapter 31).

27.13 Extrema in several variables, Lagrange multipliers and the Karush–Kuhn–Tucker conditions

In one variable, Fermat's lemma and the second derivative test (Lemma 27.6.4, Corollary 27.6.14) locate the extrema of a function. This section does the same in several variables, first for functions on open sets, then for functions restricted to a set defined by equations (Lagrange multipliers), and finally to a set defined by equations and inequalities (the Karush–Kuhn–Tucker conditions), which is the basic situation of optimisation theory. The tools are the chain rule, Taylor's formula and the implicit function theorem of the previous sections, together with one piece of convex geometry, Farkas' lemma.

27.13.1 Gradient and Hessian

Let $U \subseteq \mathbb{R}^n$ be open and $f : U \to \mathbb{R}$ differentiable at a. The *gradient* of f at a is the vector $\nabla f(a) = (\partial_1 f(a), \dots, \partial_n f(a)) \in \mathbb{R}^n$; by Proposition 27.10.3(1) it represents the derivative through the standard inner product,

$$Df(a)h = \langle \nabla f(a), h \rangle \qquad (h \in \mathbb{R}^n).$$

If $\nabla f(a) \neq 0$, the Cauchy–Schwarz inequality shows that among unit vectors h the *directional derivative* $\langle \nabla f(a), h \rangle$ is largest for $h = \nabla f(a)/\|\nabla f(a)\|$: the gradient points in the direction of steepest increase, and its length is the rate of increase in that direction. It is orthogonal to the level set through a, in the sense that $\langle \nabla f(a), \gamma'(0) \rangle = (f \circ \gamma)'(0) = 0$ for every differentiable curve γ with $\gamma(0) = a$ on which f is constant.

If f is C^2, its *Hessian* at a is the matrix $D^2 f(a) = (\partial_i \partial_j f(a))_{i,j}$, which is symmetric by Schwarz's theorem (Theorem 27.10.5). We write $D^2 f(a)(h,h) = h^T D^2 f(a) h = \sum_{i,j} \partial_i \partial_j f(a) h_i h_j$ for the associated quadratic form. With this notation Taylor's theorem (Theorem 27.10.7) for $k = 1$ reads

$$f(a+h) = f(a) + \langle \nabla f(a), h \rangle + \tfrac{1}{2} D^2 f(\xi)(h,h) \qquad \text{for some } \xi \in (a, a+h), \tag{27.2}$$

since $\sum_{|\alpha|=2} \frac{\partial^\alpha f}{\alpha!} h^\alpha = \frac{1}{2} \sum_{i,j} \partial_i \partial_j f \, h_i h_j$ (a diagonal term $\alpha = 2e_i$ has $\alpha! = 2$ and occurs once, an off-diagonal pair $\{i,j\}$ has $\alpha! = 1$ and occurs twice in the double sum). Along a line, if $g(t) = f(a + th)$, the chain rule gives

$$g'(t) = \langle \nabla f(a+th), h \rangle, \qquad g''(t) = D^2 f(a+th)(h,h). \tag{27.3}$$

A real symmetric matrix H, or its quadratic form, is *positive definite* if $h^T H h > 0$ for all $h \neq 0$, *positive semidefinite* if $h^T H h \geq 0$ for all h, *negative (semi)definite* if $-H$ is positive (semi)definite, and *indefinite* if $h^T H h$ takes both signs. By the spectral theorem (Theorem 11.10.6), $H = Q D Q^T$ with Q orthogonal, and $h^T H h = \sum_i \lambda_i y_i^2$ with $y = Q^T h$: so H is positive definite if and only if all its eigenvalues are positive, positive semidefinite if and only if they are all ≥ 0, and indefinite if and only if it has eigenvalues of both signs.

Definition 27.13.1. Let $S \subseteq \mathbb{R}^n$ and $f : S \to \mathbb{R}$. Then f has a *local minimum* at $a \in S$ if there is $\delta > 0$ with $f(x) \geq f(a)$ for all $x \in S$ with $\|x - a\| < \delta$, and a *strict local minimum* if moreover $f(x) > f(a)$ for these $x \neq a$; similarly for (strict) local maxima. A *global minimum* on S is a point a with $f(x) \geq f(a)$ for all $x \in S$. When S is given by equations or inequalities and f is the restriction of a function defined on a larger open set, one speaks of a *constrained* extremum. A point a of an open set U where f is differentiable is a *critical point* of f if $\nabla f(a) = 0$.

Proposition 27.13.2. *Let $U \subseteq \mathbb{R}^n$ be open, $f : U \to \mathbb{R}$ of class C^2, and $a \in U$.*

1. *If f has a local minimum at a, then $\nabla f(a) = 0$ and $D^2 f(a)$ is positive semidefinite.*
2. *If $\nabla f(a) = 0$ and $D^2 f(a)$ is positive definite, then f has a strict local minimum at a.*
3. *If $\nabla f(a) = 0$ and $D^2 f(a)$ is indefinite, then f has no local extremum at a (a* saddle point*).*

The same holds for maxima with "negative" in place of "positive".

Proof. (1) Let $h \in \mathbb{R}^n$ and $g(t) = f(a + th)$, defined and C^2 on an interval around 0, with a local minimum at 0. By Lemma 27.6.4 and (27.3), $0 = g'(0) = \langle \nabla f(a), h \rangle$; as h is arbitrary, $\nabla f(a) = 0$. If $g''(0) = D^2 f(a)(h,h)$ were negative, g would have a strict local maximum at 0 by Corollary 27.6.14, so $g(t) < g(0) \leq g(t)$ for small $t \neq 0$, which is absurd. Hence $D^2 f(a)(h,h) \geq 0$.

(2) The unit sphere $\{\|u\| = 1\}$ is compact (Theorem 18.6.5) and $u \mapsto D^2 f(a)(u,u)$ is continuous and positive on it, so it has a minimum $m > 0$ (Corollary 18.6.6). For $\|u\| = 1$, $|D^2 f(\xi)(u,u) - D^2 f(a)(u,u)| \le \sum_{i,j} |\partial_i \partial_j f(\xi) - \partial_i \partial_j f(a)|$, which is $< m/2$ for $\|\xi - a\| < \delta$ with δ small, by continuity of the second derivatives. Then for $0 < \|h\| < \delta$ (and $\overline{B}(a,\delta) \subseteq U$), (27.2) with $\nabla f(a) = 0$ gives

$$f(a+h) - f(a) = \tfrac{1}{2}\|h\|^2 D^2 f(\xi)\big(\tfrac{h}{\|h\|}, \tfrac{h}{\|h\|}\big) \ge \tfrac{m}{4}\|h\|^2 > 0.$$

(3) By (1), applied to f and to $-f$, a local minimum forces $D^2 f(a)$ positive semidefinite and a local maximum forces it negative semidefinite; an indefinite form is neither. □

Example 27.13.3. For $n = 2$ write $D^2 f(a) = \left(\begin{smallmatrix} A & B \\ B & C \end{smallmatrix}\right)$. Completing the square, $Ah_1^2 + 2Bh_1h_2 + Ch_2^2 = A(h_1 + \frac{B}{A}h_2)^2 + \frac{AC-B^2}{A}h_2^2$ when $A \neq 0$. So the Hessian is positive definite if and only if $A > 0$ and $AC - B^2 > 0$, negative definite if and only if $A < 0$ and $AC - B^2 > 0$, and indefinite if $AC - B^2 < 0$ (the determinant is the product of the two eigenvalues). For instance:

1. $f(x,y) = x^2 + xy + y^2 - 3x$ has the single critical point $(2,-1)$, with $A = C = 2$, $B = 1$, $AC - B^2 = 3$: a strict local minimum, in fact global, as f minus its value there is a positive definite quadratic form in $(x-2, y+1)$.

2. $f(x,y) = x^3 - 3x + y^2$ has critical points $(\pm 1, 0)$, with $D^2 f = \operatorname{diag}(6x, 2)$: a strict local minimum at $(1,0)$ and a saddle point at $(-1,0)$. The local minimum is not global, since $f(x,0) \to -\infty$ as $x \to -\infty$.

3. $x^2 + y^4$, $x^2 - y^4$ and $x^2 + y^3$ all have the critical point 0 with the semidefinite Hessian $\operatorname{diag}(2,0)$, and they have a minimum, a saddle and a saddle there: when the Hessian is degenerate the test says nothing, as in Counterexample 27.6.15.

Counterexample 27.13.4. Checking all lines through a is not enough. Let $f(x,y) = (y - x^2)(y - 3x^2)$. On every line through 0 the restriction of f has a strict local minimum at 0: on the x-axis $f = 3x^4$, and on $y = mx$ we get $f = m^2x^2 - 4mx^3 + 3x^4$, whose second derivative at 0 is $2m^2 > 0$ for $m \neq 0$ (and on the y-axis $f = y^2$). But $f < 0$ between the two parabolas, at $(x, 2x^2)$, arbitrarily close to 0; so 0 is not a local minimum. Here $D^2 f(0) = \operatorname{diag}(0,2)$ is only semidefinite, as Proposition 27.13.2(2) requires.

27.13.2 Lagrange multipliers

Suppose we want the extrema of $f(x,y)$ on the curve $M = \{h(x,y) = 0\}$. Walking along M, the value of f stops increasing at a point a where M does not cross the level curve of f through a but touches it. There the two curves have the same tangent line, so their normals $\nabla f(a)$ and $\nabla h(a)$ are parallel: $\nabla f(a) = \lambda \nabla h(a)$ for some number λ, the *Lagrange multiplier*. In this way a constrained problem in n unknowns becomes an unconstrained system of $n+1$ equations ($\nabla f = \lambda \nabla h$ and $h = 0$) in $n+1$ unknowns. To prove this we need curves inside the constraint set with a prescribed velocity; they are provided by the submersion theorem.

Lemma 27.13.5. *Let $U \subseteq \mathbb{R}^n$ be open, $h = (h_1, \dots, h_q) \colon U \to \mathbb{R}^q$ of class C^k with $k \ge 1$, and $a \in U$ with $h(a) = 0$ and $Dh(a)$ surjective, that is, with $\nabla h_1(a), \dots, \nabla h_q(a)$ linearly independent. For every $d \in \ker Dh(a)$ there are $\varepsilon > 0$ and a C^k curve $x \colon (-\varepsilon, \varepsilon) \to U$ with $x(0) = a$, $x'(0) = d$ and $h(x(t)) = 0$ for all t.*

Proof. By Theorem 27.12.4(1) there is a C^k-diffeomorphism ψ from an open $V \ni a$ onto an open $W \subseteq \mathbb{R}^n$ with $h \circ \psi^{-1} = \pi$, where $\pi(z) = (z_1, \dots, z_q)$. (If $q = 0$ there is nothing to prove: take $x(t) = a + td$.) Thus $h = \pi \circ \psi$ on V, so $\pi(\psi(a)) = h(a) = 0$ and, by the chain rule,

$\pi(D\psi(a)d) = Dh(a)d = 0$. Put $v = D\psi(a)d$ and $x(t) = \psi^{-1}(\psi(a) + tv)$, defined for $|t| < \varepsilon$ since W is open. Then $h(x(t)) = \pi(\psi(a)) + t\pi(v) = 0$, and by the chain rule and Theorem 27.12.2, $x'(0) = D\psi(a)^{-1}v = d$. □

Theorem 27.13.6 (Lagrange multipliers). *Let $U \subseteq \mathbb{R}^n$ be open, $f : U \to \mathbb{R}$ and $h = (h_1, \dots, h_q) \colon U \to \mathbb{R}^q$ of class C^1, and $M = \{x \in U : h(x) = 0\}$. Let $a \in M$ be a point where $\nabla h_1(a), \dots, \nabla h_q(a)$ are linearly independent. If $f|_M$ has a local extremum at a, there are unique numbers $\lambda_1, \dots, \lambda_q$ with*

$$\nabla f(a) = \lambda_1 \nabla h_1(a) + \cdots + \lambda_q \nabla h_q(a). \tag{27.4}$$

Equivalently, (a, λ) is a critical point of the Lagrangian $L(x, \lambda) = f(x) - \sum_j \lambda_j h_j(x)$ *on $U \times \mathbb{R}^q$.*

Proof. Let $d \in \ker Dh(a)$, and let $x(t)$ be the curve of Lemma 27.13.5. Since $x(t) \in M$ and $x(t) \to a$, the function $f \circ x$ has a local extremum at $t = 0$, so by Lemma 27.6.4 and the chain rule $0 = (f \circ x)'(0) = \langle \nabla f(a), d \rangle$. Thus $\nabla f(a)$ is orthogonal to $\ker Dh(a)$. Now $\ker Dh(a)$ is exactly the orthogonal complement of the span R of the rows $\nabla h_j(a)$ of the Jacobian matrix, so $\nabla f(a) \in (R^\perp)^\perp = R$ (in a finite-dimensional inner product space $(R^\perp)^\perp = R$, since $R \subseteq (R^\perp)^\perp$ and both have dimension $\dim R$). Uniqueness of the λ_j is the linear independence of the $\nabla h_j(a)$. Finally, $\partial L/\partial x_i = 0$ for all i is (27.4), and $\partial L/\partial \lambda_j = -h_j = 0$ is the constraint. □

The space $\ker Dh(a)$ is the *tangent space* of M at a: by the lemma it is the set of velocities of curves in M through a, and by the submersion theorem M is, near a, a submanifold of dimension $n - q$ in the sense of Chapter 33. The theorem says that at a constrained extremum the gradient of f is normal to M. The linear independence hypothesis cannot be dropped:

Counterexample 27.13.7. Minimise $f(x, y) = x$ on the cusp $M = \{h = 0\}$, $h(x, y) = y^2 - x^3$. On M, $x^3 = y^2 \geq 0$, so $x \geq 0$ and the minimum is at $(0, 0)$. But $\nabla f = (1, 0)$, while $\nabla h = (-3x^2, 2y)$ vanishes at the origin, so no λ satisfies $\nabla f(0) = \lambda \nabla h(0)$. Solving the Lagrange system $1 = -3\lambda x^2$, $0 = 2\lambda y$, $y^2 = x^3$ gives no solution at all: the method finds nothing, and the minimum sits at the singular point of M. In practice one must examine separately the points of M where the gradients of the constraints are dependent.

Example 27.13.8.

1. *Extrema of $x + y$ on the circle $x^2 + y^2 = 1$.* The circle is compact, so both extrema exist (Corollary 18.6.6), and $\nabla h = (2x, 2y) \neq 0$ on it. The system $(1, 1) = \lambda(2x, 2y)$ gives $x = y = \frac{1}{2\lambda}$, and $x^2 + y^2 = 1$ gives $(x, y) = \pm(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})$: maximum $\sqrt{2}$, minimum $-\sqrt{2}$.

2. *The inequality of the means.* Maximise $f(x) = x_1 x_2 \cdots x_k$ on the compact set $\Delta = \{x : x_i \geq 0, \sum_i x_i = k\}$. The maximum is positive (take all $x_i = 1$), so it is attained at a point with all $x_i > 0$, which is a local maximum of f on $M = \{x \in U : \sum_i x_i = k\}$ with $U = \{x_i > 0\}$. With $h = \sum_i x_i - k$, $\nabla h = (1, \dots, 1)$ and $\partial_i f = f(x)/x_i$, so $f(x)/x_i = \lambda$ for all i: all x_i are equal, hence equal to 1, and $f \leq 1$ on Δ. By homogeneity, $\sqrt[k]{x_1 \cdots x_k} \leq \frac{1}{k} \sum_i x_i$ for $x_i \geq 0$, which recovers Corollary 27.7.7 by a quite different route.

3. *Eigenvectors as critical points.* Let A be a real symmetric $n \times n$ matrix and $q(x) = x^T A x$, so that $\nabla q(x) = 2Ax$. On the compact unit sphere, $h(x) = \|x\|^2 - 1$ with $\nabla h(x) = 2x \neq 0$, the function q has a maximum at some u, and (27.4) reads $Au = \lambda u$: *u is an eigenvector*, and $\lambda = u^T A u$ is the maximum of q on the sphere, the largest eigenvalue. This proves, without the fundamental theorem of algebra, that a real symmetric matrix has a real eigenvector, which is the key step of Theorem 11.10.6(2). More generally the critical points of the *Rayleigh quotient* $x^T Ax / x^T x$ on $\mathbb{R}^n \setminus \{0\}$ are exactly the eigenvectors.

4. *Nearest points.* Let $h\colon \mathbb{R}^n \to \mathbb{R}$ be C^1, $M = \{h = 0\}$ nonempty with $\nabla h \neq 0$ on M, and $p \in \mathbb{R}^n$. Since M is closed, $f(x) = \|x - p\|^2$ attains a minimum on M (on the compact set $M \cap \overline{B}(p, R)$ for R large). At the minimum a, $2(a - p) = \lambda \nabla h(a)$: *the segment from p to the nearest point is normal to M.* For the hyperplane $\langle n, x\rangle = c$ this gives $a = p + tn$ with $t = (c - \langle n, p\rangle)/\|n\|^2$, and the familiar distance $|c - \langle n, p\rangle|/\|n\|$.

The multiplier has a meaning of its own: it is the rate at which the optimal value changes when the constraint is relaxed.

Proposition 27.13.9. *Let $f, h\colon U \to \mathbb{R}$ be C^1 on an open $U \subseteq \mathbb{R}^n$, J an open interval, and $c \mapsto x(c)$ a differentiable map $J \to U$ such that for every $c \in J$, $h(x(c)) = c$ and $\nabla f(x(c)) = \lambda(c)\nabla h(x(c))$ for some number $\lambda(c)$. Then $V(c) = f(x(c))$ is differentiable on J and $V'(c) = \lambda(c)$.*

Proof. By the chain rule, $V'(c) = \langle \nabla f(x(c)), x'(c)\rangle = \lambda(c)\langle \nabla h(x(c)), x'(c)\rangle = \lambda(c)\frac{d}{dc}h(x(c)) = \lambda(c)$. □

For example, the largest product xy with $x + y = c$ is $V(c) = c^2/4$, at $x = y = c/2$, where $(y, x) = \frac{c}{2}(1, 1)$: indeed $\lambda = c/2 = V'(c)$. In economics, where f is a profit and $h \leq c$ a budget, λ is the *shadow price* of the resource: the extra profit that one more unit of it would bring. In mechanics, where Lagrange introduced the method in his *Mécanique analytique* (1788), $\lambda\nabla h$ is the force by which the constraint keeps the system on M.

27.13.3 Second-order conditions

A critical point of the Lagrangian need not be an extremum, and as in Proposition 27.13.2 one looks at second derivatives. The correct quadratic form is not the Hessian of f but that of the Lagrangian, and only in tangent directions: the curvature of M contributes through the multipliers.

Theorem 27.13.10. *Let f and $h = (h_1, \dots, h_q)$ be C^2 on the open set $U \subseteq \mathbb{R}^n$, $M = \{h = 0\}$, and $a \in M$ with $\nabla f(a) = \sum_j \lambda_j \nabla h_j(a)$. Put $L = f - \sum_j \lambda_j h_j$ (with these fixed λ_j) and $T = \ker Dh(a)$.*

1. *If $\nabla h_1(a), \dots, \nabla h_q(a)$ are linearly independent and $f|_M$ has a local minimum at a, then $D^2L(a)(d, d) \geq 0$ for all $d \in T$.*
2. *If $D^2L(a)(d, d) > 0$ for all nonzero $d \in T$, then $f|_M$ has a strict local minimum at a.*

Proof. Note that $\nabla L(a) = 0$ and that $L = f$ on M.

(1) Let $d \in T$ and let $x(t)$ be the C^2 curve of Lemma 27.13.5, and $\varphi(t) = f(x(t)) = L(x(t))$. Differentiating $\varphi'(t) = \sum_i \partial_i L(x(t))x_i'(t)$ once more,

$$\varphi''(0) = \sum_{i,j} \partial_j\partial_i L(a)x_i'(0)x_j'(0) + \sum_i \partial_i L(a)x_i''(0) = D^2L(a)(d, d),$$

because $\nabla L(a) = 0$; this is where the Lagrangian, rather than f, is needed, since $x''(0)$ is unknown. Now φ has a local minimum at 0, and as in the proof of Proposition 27.13.2(1), $\varphi''(0) \geq 0$.

(2) Suppose not. Then there are $x_k \in M$ with $x_k \neq a$, $x_k \to a$ and $f(x_k) \leq f(a)$. Write $x_k = a + t_k d_k$ with $t_k = \|x_k - a\| \to 0$ and $\|d_k\| = 1$; passing to a subsequence (the unit sphere is compact), $d_k \to d$ with $\|d\| = 1$. From $h(x_k) = h(a) = 0$ we get $0 = (h(a + t_k d_k) - h(a))/t_k \to Dh(a)d$, so $d \in T$. By (27.2) for L, with $\nabla L(a) = 0$,

$$0 \geq f(x_k) - f(a) = L(x_k) - L(a) = \tfrac{1}{2}t_k^2 D^2L(\xi_k)(d_k, d_k)$$

with $\xi_k \to a$. Dividing by $t_k^2/2$ and letting $k \to \infty$, $D^2L(a)(d, d) \leq 0$, contradicting the hypothesis. □

Example 27.13.11. Let M be the parabola $y = x^2$, $h(x,y) = y - x^2$, and $f(x,y) = y + cx^2$ with a constant c. At $a = 0$, $\nabla f = (0,1) = 1 \cdot \nabla h(0)$, so $\lambda = 1$ and $T = \mathbb{R}(1,0)$. Then $D^2L = D^2f - D^2h = \operatorname{diag}(2c+2, 0)$, so $D^2L(0)(e_1,e_1) = 2(1+c)$: by the theorem, 0 is a strict local minimum of $f|_M$ for $c > -1$ and a strict local maximum for $c < -1$. This is correct, since $f = (1+c)x^2$ on M. The Hessian of f alone gives $D^2f(0)(e_1,e_1) = 2c$, which has the wrong sign for $-1 < c < 0$: the term $-\lambda D^2h$ records the bending of M.

Example 27.13.12 (The bordered Hessian in two variables)**.** Let $n = 2$, $q = 1$, $\nabla h(a) = (h_x, h_y) \neq 0$ and $D^2L(a) = \left(\begin{smallmatrix} L_{xx} & L_{xy} \\ L_{xy} & L_{yy} \end{smallmatrix}\right)$. Then T is spanned by $d = (-h_y, h_x)$ and

$$D^2L(a)(d,d) = L_{xx}h_y^2 - 2L_{xy}h_xh_y + L_{yy}h_x^2 = -\det\begin{pmatrix} 0 & h_x & h_y \\ h_x & L_{xx} & L_{xy} \\ h_y & L_{xy} & L_{yy} \end{pmatrix},$$

as one sees by expanding the determinant along the first row. So if the *bordered Hessian* on the right has negative determinant, a is a strict local minimum of $f|_M$, and if it has positive determinant, a strict local maximum. In Example 27.13.8(1), at $\pm(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})$ we have $\lambda = \pm\frac{1}{\sqrt{2}}$, $D^2L = -2\lambda I$ and $(h_x, h_y) = \pm(\sqrt{2}, \sqrt{2})$; the determinant is $-(-2\lambda)(h_x^2 + h_y^2) = 8\lambda$, positive at the maximum and negative at the minimum.

27.13.4 Inequality constraints and Farkas' lemma

Many problems constrain the unknowns by inequalities: quantities are nonnegative, budgets are bounded. Consider

$$\text{minimise } f(x) \quad \text{subject to} \quad g_i(x) \leq 0 \ (1 \leq i \leq p), \qquad h_j(x) = 0 \ (1 \leq j \leq q), \tag{27.5}$$

where $f, g_i, h_j \colon U \to \mathbb{R}$ are C^1 on an open $U \subseteq \mathbb{R}^n$; the *feasible set* is the set F of $x \in U$ satisfying the constraints. At a feasible point a, the inequality $g_i \leq 0$ is *active* if $g_i(a) = 0$; let $I(a)$ be the set of active indices. An inactive constraint, $g_i(a) < 0$, still holds near a and plays no role locally; an active one behaves like a wall.

To see what to expect, take one inequality $g \leq 0$ and no equations. If the minimum a is interior ($g(a) < 0$), then $\nabla f(a) = 0$. If $g(a) = 0$, the minimum lies on the wall $\{g = 0\}$, so $\nabla f(a) = \lambda \nabla g(a)$ by Theorem 27.13.6; and now the *sign* of λ is determined: moving into the feasible region, in the direction $-\nabla g(a)$, must not decrease f, so $\nabla f(a)$ points into the feasible region and $-\nabla f(a) = \mu \nabla g(a)$ with $\mu \geq 0$. The general statement needs a lemma of linear algebra over the ordered field $\mathbb{R}$.

Lemma 27.13.13 (Farkas)**.** *Let $v_1, \dots, v_r, b \in \mathbb{R}^n$. Exactly one of the following holds:*

1. *$b = c_1v_1 + \cdots + c_rv_r$ with all $c_i \geq 0$;*
2. *there is $w \in \mathbb{R}^n$ with $\langle w, v_i \rangle \leq 0$ for all i and $\langle w, b \rangle > 0$.*

Geometrically: either b lies in the convex cone $C = \{\sum_i c_iv_i : c_i \geq 0\}$, or a hyperplane through 0, with normal w, separates b from C.

Proof. Both cannot hold, since then $\langle w, b \rangle = \sum_i c_i \langle w, v_i \rangle \leq 0$. Assume (1) fails, that is, $b \notin C$.

Step 1: C is closed. First, every $y \in C$ is a nonnegative combination of a linearly independent subset of the v_i (*Carathéodory's lemma*). Indeed, choose $y = \sum_{i \in S} c_iv_i$ with all $c_i > 0$ and S as small as possible. If the v_i with $i \in S$ were dependent, there would be a relation $\sum_{i \in S} \gamma_iv_i = 0$ with some $\gamma_i > 0$ (change the sign of γ if necessary); with $t = \min\{c_i/\gamma_i : \gamma_i > 0\}$, $y = \sum_{i \in S}(c_i - t\gamma_i)v_i$ has nonnegative coefficients, one of which

vanishes, contradicting the minimality of S. So C is the union of the finitely many cones C_S spanned by linearly independent subsets S, and it suffices that each C_S is closed. The map $\mathbb{R}^S \to \mathbb{R}^n$, $c \mapsto \sum_{i\in S} c_i v_i$, is injective and linear, so on the compact unit sphere of $\mathbb{R}^S$ its norm has a positive minimum m, and $\|\sum_i c_i v_i\| \geq m\|c\|$. If $\sum_i c_i^{(k)} v_i \to y$ with $c^{(k)} \geq 0$, then $(c^{(k)})$ is a Cauchy sequence, with a limit $c \geq 0$, and $y = \sum_i c_i v_i \in C_S$.

Step 2: a nearest point. The continuous function $x \mapsto \|b - x\|$ attains a minimum on the compact set $C \cap \overline{B}(b, \|b\|)$, which contains 0; the minimum point p is then a nearest point to b in all of C.

Step 3: separation. Let $w = b - p$, nonzero since $b \notin C$. For $c \in C$ and $0 < t \leq 1$, $(1-t)p + tc \in C$, so $\|w - t(c-p)\|^2 \geq \|w\|^2$, that is, $-2t\langle w, c-p\rangle + t^2\|c-p\|^2 \geq 0$; dividing by t and letting $t \to 0$, $\langle w, c-p\rangle \leq 0$. With $c = 0$ and $c = 2p$ this gives $\langle w, p\rangle = 0$, hence $\langle w, c\rangle \leq 0$ for all $c \in C$, in particular $\langle w, v_i\rangle \leq 0$. Finally $\langle w, b\rangle = \langle w, w+p\rangle = \|w\|^2 > 0$. □

Theorem 27.13.14 (Karush–Kuhn–Tucker)**.** *In the situation* (27.5)*, let $a \in F$ be a local minimum of f on F, and assume the* linear independence constraint qualification*: the gradients $\nabla g_i(a)$ for $i \in I(a)$ and $\nabla h_j(a)$ for $1 \leq j \leq q$ are linearly independent. Then there are unique numbers $\mu_1, \ldots, \mu_p$ and $\lambda_1, \ldots, \lambda_q$ with*

$$\nabla f(a) + \sum_{i=1}^{p} \mu_i \nabla g_i(a) + \sum_{j=1}^{q} \lambda_j \nabla h_j(a) = 0, \qquad \mu_i \geq 0, \qquad \mu_i g_i(a) = 0 \quad (1 \leq i \leq p). \tag{27.6}$$

The last condition, *complementary slackness*, says that $\mu_i = 0$ unless the i-th constraint is active. The signs of the λ_j are not restricted, and for $p = 0$ the theorem is Theorem 27.13.6 for minima (with $-\lambda_j$ in place of λ_j).

Proof. Write $I = I(a)$.

Step 1. Let $d \in \mathbb{R}^n$ with $\langle \nabla g_i(a), d\rangle < 0$ for $i \in I$ and $Dh(a)d = 0$. We show $\langle \nabla f(a), d\rangle \geq 0$. The $\nabla h_j(a)$ are linearly independent, so Lemma 27.13.5 gives a C^1 curve $x(t)$ with $x(0) = a$, $x'(0) = d$ and $h(x(t)) = 0$. For $i \in I$, $\varphi_i(t) = g_i(x(t))$ has $\varphi_i(0) = 0$ and $\varphi_i'(0) = \langle \nabla g_i(a), d\rangle < 0$, so $\varphi_i(t) < 0$ for small $t > 0$; for $i \notin I$, $g_i(x(t)) < 0$ for small t by continuity. So $x(t) \in F$ for small $t > 0$, and since $x(t) \to a$, $f(x(t)) \geq f(a)$ for small $t > 0$. Hence $\langle \nabla f(a), d\rangle = \lim_{t\to 0^+}(f(x(t)) - f(a))/t \geq 0$.

Step 2. The same holds if only $\langle \nabla g_i(a), d\rangle \leq 0$ for $i \in I$ and $Dh(a)d = 0$. Indeed, the linear map $d \mapsto ((\langle \nabla g_i(a), d\rangle)_{i\in I}, Dh(a)d)$ has linearly independent rows, hence is surjective, so there is d_0 with $\langle \nabla g_i(a), d_0\rangle = -1$ for $i \in I$ and $Dh(a)d_0 = 0$. For $\varepsilon > 0$, $d + \varepsilon d_0$ satisfies the hypothesis of Step 1, so $\langle \nabla f(a), d + \varepsilon d_0\rangle \geq 0$; let $\varepsilon \to 0$.

Step 3. Apply Lemma 27.13.13 to $b = -\nabla f(a)$ and the vectors $\nabla g_i(a)$ ($i \in I$), $\nabla h_j(a)$ and $-\nabla h_j(a)$ ($1 \leq j \leq q$). Alternative (2) would give w with $\langle \nabla g_i(a), w\rangle \leq 0$ for $i \in I$, $\langle \pm\nabla h_j(a), w\rangle \leq 0$, that is, $Dh(a)w = 0$, and $\langle \nabla f(a), w\rangle < 0$, contradicting Step 2. So alternative (1) holds: $-\nabla f(a) = \sum_{i\in I} \mu_i \nabla g_i(a) + \sum_j (c_j^+ - c_j^-)\nabla h_j(a)$ with $\mu_i, c_j^\pm \geq 0$. Put $\lambda_j = c_j^+ - c_j^-$ and $\mu_i = 0$ for $i \notin I$; this gives (27.6). Uniqueness follows from the linear independence, since $\mu_i = 0$ is forced for $i \notin I$. □

The conditions were found by W. Karush in his 1939 master's thesis and, independently, by H. W. Kuhn and A. W. Tucker in 1951, at the start of nonlinear programming. In the language of the introduction to this subsection: at a constrained minimum, $-\nabla f(a)$, the direction of steepest descent, lies in the cone spanned by the outward normals $\nabla g_i(a)$ of the active walls (and the normal space of the equations), so that every feasible direction is uphill to first order.

Counterexample 27.13.15. Without a constraint qualification the conclusion can fail. Minimise $f(x,y) = x$ subject to $g_1 = y - x^3 \le 0$ and $g_2 = -y \le 0$. Feasibility means $0 \le y \le x^3$, so $x \ge 0$, and the minimum is at $(0,0)$, where both constraints are active. There $\nabla f = (1,0)$, $\nabla g_1 = (0,1)$ and $\nabla g_2 = (0,-1)$, and $(1,0) + \mu_1(0,1) + \mu_2(0,-1) = 0$ is impossible. The two active gradients are dependent: the feasible set has a cusp at the origin, and the linearised constraints $\langle \nabla g_i, d\rangle \le 0$, which allow every $d = (d_1, 0)$, do not describe the feasible directions, which have $d_1 \ge 0$.

Remark 27.13.16. Reading the proof again shows that weaker hypotheses suffice for the existence of multipliers (not for their uniqueness, which used the full linear independence).

1. *Mangasarian–Fromovitz condition:* the $\nabla h_j(a)$ are linearly independent and there is d_0 with $Dh(a)d_0 = 0$ and $\langle \nabla g_i(a), d_0\rangle < 0$ for $i \in I(a)$. Step 1 used only the independence of the $\nabla h_j(a)$, Step 2 only the existence of such a d_0, and Step 3 nothing else.

2. *Affine constraints:* if all g_i and h_j are affine, no qualification is needed. Indeed, for d with $\langle \nabla g_i(a), d\rangle \le 0$ ($i \in I(a)$) and $Dh(a)d = 0$, the points $a + td$ are feasible for small $t > 0$ (for active i, $g_i(a+td) = t\langle \nabla g_i(a), d\rangle \le 0$), so $\langle \nabla f(a), d\rangle \ge 0$ directly, and Step 3 applies.

27.13.5 Convex problems

The conditions of the Karush–Kuhn–Tucker theorem are necessary. For convex problems they are also sufficient, and give global minima. A function f on a convex set $K \subseteq \mathbb{R}^n$ is *convex* if $f((1-t)x + ty) \le (1-t)f(x) + tf(y)$ for all $x, y \in K$ and $t \in [0,1]$, that is, if its restriction to every segment is convex in the sense of Definition 27.6.16, and *strictly convex* if the inequality is strict whenever $x \ne y$ and $0 < t < 1$. A sublevel set $\{x \in K : f(x) \le c\}$ of a convex function is convex, and so is the zero set of an affine function; hence the feasible set of (27.5) is convex when U is convex, the g_i are convex and the h_j are affine.

Lemma 27.13.17. *Let $U \subseteq \mathbb{R}^n$ be open and convex, and $f\colon U \to \mathbb{R}$ convex and C^1. Then $f(y) \ge f(x) + \langle \nabla f(x), y - x\rangle$ for all $x, y \in U$. If f is C^2 with positive semidefinite Hessian everywhere, then f is convex.*

Proof. We may assume $x \ne y$. As U is open, the points $x - \varepsilon(y-x)$ and $y + \varepsilon(y-x)$ lie in U for small $\varepsilon > 0$, and as U is convex so does the segment joining them. Hence $\varphi(t) = f(x + t(y-x))$ is defined on the open interval $J = (-\varepsilon, 1+\varepsilon)$, it is convex there (being the restriction of f to a segment), and it is differentiable with $\varphi'(0) = \langle \nabla f(x), y - x\rangle$ by the chain rule. By Proposition 27.6.18(2), $\varphi(1) \ge \varphi(0) + \varphi'(0)$, which is the inequality. For the second statement, $\varphi''(t) = D^2 f(x + t(y-x))(y-x, y-x) \ge 0$ on J by (27.3), so φ is convex by Proposition 27.6.18(3); this is convexity of f on the segment $[x, y]$. □

Theorem 27.13.18. *In (27.5), let U be convex, f and $g_1, \dots, g_p$ convex and $h_1, \dots, h_q$ affine. If $a \in F$ and numbers μ_i, λ_j satisfy (27.6), then a is a global minimum of f on F. If f is strictly convex, it is the only one.*

Proof. Let $x \in F$. By Lemma 27.13.17 and (27.6),

$$f(x) - f(a) \ge \langle \nabla f(a), x - a\rangle = -\sum_i \mu_i \langle \nabla g_i(a), x - a\rangle - \sum_j \lambda_j \langle \nabla h_j(a), x - a\rangle.$$

Since h_j is affine, $\langle \nabla h_j(a), x - a\rangle = h_j(x) - h_j(a) = 0$. By the lemma again and complementary slackness, $\mu_i \langle \nabla g_i(a), x - a\rangle \le \mu_i(g_i(x) - g_i(a)) = \mu_i g_i(x) \le 0$. Hence $f(x) \ge f(a)$. If f is strictly convex and $f(x) = f(a)$ with $x \ne a$, then the midpoint $m = \tfrac{1}{2}(x + a)$ is feasible (F is convex) and $f(m) < \tfrac{1}{2}f(x) + \tfrac{1}{2}f(a) = f(a)$, a contradiction. □

Example 27.13.19 (Water-filling)**.** Given $\alpha_1, \dots, \alpha_n > 0$ and $P > 0$, maximise $\sum_i \log(\alpha_i + x_i)$ subject to $x_i \geq 0$ and $\sum_i x_i = P$. (In information theory, x_i is the power sent through the i-th of n parallel channels with noise level α_i, and $\frac{1}{2}\log(1 + x_i/\alpha_i)$ is its capacity, so this maximises the total capacity for a total power P.) Minimise the strictly convex function $f(x) = -\sum_i \log(\alpha_i + x_i)$ on $U = \{x_i > -\alpha_i\}$, with $g_i = -x_i$ and $h = \sum_i x_i - P$. The conditions (27.6) read

$$-\frac{1}{\alpha_i + x_i} - \mu_i + \lambda = 0, \qquad \mu_i \geq 0, \qquad \mu_i x_i = 0.$$

So $\lambda \geq 1/(\alpha_i + x_i) > 0$; put $\nu = 1/\lambda$. If $x_i > 0$, then $\mu_i = 0$ and $x_i = \nu - \alpha_i$; if $x_i = 0$, then $\lambda \geq 1/\alpha_i$, that is, $\alpha_i \geq \nu$. In both cases

$$x_i = \max(0, \nu - \alpha_i),$$

and ν is fixed by $\sum_i \max(0, \nu - \alpha_i) = P$; the left side is continuous and strictly increasing in $\nu \geq \min_i \alpha_i$, from 0 to ∞, so there is exactly one such ν (Theorem 27.4.8). Conversely this x, with $\lambda = 1/\nu$ and $\mu_i = \lambda - 1/(\alpha_i + x_i) \geq 0$, satisfies the conditions, so by Theorem 27.13.18 it is the unique optimum. The picture: a vessel whose floor has height α_i over the i-th cell is filled with a volume P of water; the water settles at level ν, and x_i is the depth over the i-th cell. The noisiest channels get nothing.

Example 27.13.20 (Maximum entropy and the Boltzmann distribution)**.** Let $E_1, \dots, E_N$ be real numbers (the energies of the states of a physical system), not all equal, and $\min_i E_i < E < \max_i E_i$. Among probability vectors p with $p_i > 0$, $\sum_i p_i = 1$ and mean energy $\sum_i p_i E_i = E$, which one has the largest *entropy* $H(p) = -\sum_i p_i \log p_i$? The function $-H(p) = \sum_i \phi(p_i)$, $\phi(t) = t \log t$, is strictly convex on $U = \{p_i > 0\}$: $\phi''(t) = 1/t > 0$, so ϕ is strictly convex (Proposition 27.6.18(3)), and for $p \neq p'$ the convexity inequality is strict in a coordinate where they differ. The two constraints are affine. The conditions (27.6) for minimising $-H$ read $\log p_i + 1 + \lambda_1 + \lambda_2 E_i = 0$, so

$$p_i = \frac{e^{-\beta E_i}}{Z(\beta)}, \qquad Z(\beta) = \sum_k e^{-\beta E_k},$$

with $\beta = \lambda_2$, after normalising. This is the *Boltzmann (Gibbs) distribution* of statistical mechanics, β being the inverse temperature and Z the *partition function*. It remains to choose β with mean energy E. The mean $m(\beta) = \sum_k E_k e^{-\beta E_k}/Z(\beta)$ is continuous, has derivative $m'(\beta) = -(\sum_k E_k^2 p_k - m(\beta)^2) < 0$, minus the variance of the energy, which is positive since the E_k are not all equal, and tends to $\min E_k$ as $\beta \to +\infty$ and to $\max E_k$ as $\beta \to -\infty$. So exactly one β gives $m(\beta) = E$, and by Theorem 27.13.18 the corresponding p is the unique entropy maximiser. Without the energy constraint ($\lambda_2 = 0$) the maximiser is the uniform distribution, with $H = \log N$.

Remark 27.13.21 (Duality). For (27.5) define the Lagrangian $L(x, \mu, \lambda) = f(x) + \sum_i \mu_i g_i(x) + \sum_j \lambda_j h_j(x)$ and the *dual function* $\theta(\mu, \lambda) = \inf_{x \in U} L(x, \mu, \lambda)$. For $\mu \geq 0$ and $x \in F$, $L(x, \mu, \lambda) \leq f(x)$, so

$$\theta(\mu, \lambda) \leq \inf_F f \qquad (\mu \geq 0) \qquad (\textit{weak duality}) :$$

every choice of multipliers gives a lower bound for the minimum. In the convex situation of Theorem 27.13.18, if (a, μ, λ) satisfies the conditions (27.6), then $x \mapsto L(x, \mu, \lambda)$ is convex with vanishing gradient at a, so by Lemma 27.13.17 it is minimal at a, and $\theta(\mu, \lambda) = L(a, \mu, \lambda) = f(a)$ by complementary slackness and $h(a) = 0$: the bound is attained, and the multipliers solve the *dual problem* of maximising θ over $\mu \geq 0$. For convex problems with a strictly feasible point (*Slater's condition*) the maximum of the dual equals the minimum of the primal even

without assuming that the minimum is attained [BV04, Chapter 5]; for linear programmes this is the duality theorem of linear programming, a consequence of Farkas' lemma. The point $(a, (\mu, \lambda))$ is then a saddle point of L: a minimum in x and a maximum in (μ, λ) with $\mu \geq 0$.

27.14 Ordinary differential equations

Definition 27.14.1. Let $D \subseteq \mathbb{R} \times \mathbb{R}^n$ be open and $F\colon D \to \mathbb{R}^n$ continuous. F is *locally Lipschitz in x* if every point of D has a neighbourhood N and L with $\|F(t,x) - F(t,y)\| \leq L\|x - y\|$ for $(t,x), (t,y) \in N$; by the mean value inequality this holds if F is C^1. A *solution* of $x' = F(t,x)$ is a differentiable map $\varphi\colon J \to \mathbb{R}^n$ on an interval with $(t, \varphi(t)) \in D$ and $\varphi'(t) = F(t, \varphi(t))$. By Theorem 27.8.3, this is equivalent to continuity of φ and $\varphi(t) = \varphi(t_0) + \int_{t_0}^{t} F(s, \varphi(s))\, ds$.

Lemma 27.14.2 (Grönwall)**.** *If $u\colon [t_0, t_1] \to [0, \infty)$ is continuous and $u(t) \leq C + L\int_{t_0}^{t} u$ with $C, L \geq 0$, then $u(t) \leq Ce^{L(t-t_0)}$.*

Proof. Let $v(t) = C + L\int_{t_0}^{t} u$. Then $v' = Lu \leq Lv$, so $(e^{-L(t-t_0)}v)' \leq 0$, and $u \leq v \leq v(t_0)e^{L(t-t_0)} = Ce^{L(t-t_0)}$. □

Theorem 27.14.3 (Picard–Lindelöf)**.** *Let F be continuous and locally Lipschitz in x, and $(t_0, x_0) \in D$.*

1. *There is $\delta > 0$ and a solution on $[t_0 - \delta, t_0 + \delta]$ with $\varphi(t_0) = x_0$.*
2. *Two solutions on intervals $J_1, J_2 \ni t_0$ with the same value at t_0 agree on $J_1 \cap J_2$.*
3. *There is a unique* maximal *solution, defined on an open interval (α, β); if $\beta < \infty$, then $(t, \varphi(t))$ leaves every compact subset of D as $t \to \beta$, and similarly at α.*

Proof. (1) Choose $a, b > 0$ such that $R = [t_0 - a, t_0 + a] \times \overline{B}(x_0, b) \subseteq D$ and F is L-Lipschitz in x on R; let $M = \sup_R \|F\|$ (finite by compactness) and $\delta = \min(a, b/(M+1), 1/(2L+1))$. On the complete metric space X of continuous maps $[t_0 - \delta, t_0 + \delta] \to \overline{B}(x_0, b)$ with the supremum metric (Proposition 18.7.2), $T\varphi(t) = x_0 + \int_{t_0}^{t} F(s, \varphi(s))\, ds$ satisfies $\|T\varphi(t) - x_0\| \leq M\delta \leq b$ and $\|T\varphi - T\psi\| \leq L\delta\|\varphi - \psi\| \leq \frac{1}{2}\|\varphi - \psi\|$. Its fixed point is a solution.

(2) The set of $t \in J_1 \cap J_2$ where the solutions agree is closed and contains t_0. If they agree at t_1, near $(t_1, \varphi(t_1))$ F is L-Lipschitz, and $u = \|\varphi_1 - \varphi_2\|$ satisfies $u(t) \leq L|\int_{t_1}^{t} u|$ for t near t_1, so $u = 0$ near t_1 by Lemma 27.14.2 (with $C = 0$, on both sides). So the set is open, and equals the connected set $J_1 \cap J_2$.

(3) By (2), the solutions with $\varphi(t_0) = x_0$ glue to a solution on the union of their intervals, which is maximal; the interval is open because a solution on a closed end could be continued by (1). Suppose $\beta < \infty$ and $(t_k, \varphi(t_k)) \in K$ for a compact $K \subseteq D$ and $t_k \to \beta$. By compactness there are a, b, L, M as in (1) valid for all rectangles centred at points of K (cover K by finitely many rectangles of half the size), hence a uniform δ. For $t_k > \beta - \delta/2$, the solution through $(t_k, \varphi(t_k))$ exists up to $t_k + \delta > \beta$ and extends φ by (2), a contradiction. □

Counterexample 27.14.4.

1. Without the Lipschitz condition uniqueness fails: $x' = 3x^{2/3}$, $x(0) = 0$ has the solutions $x = 0$ and $x = t^3$.
2. Solutions need not exist for all time: $x' = x^2$, $x(0) = 1$ has maximal solution $x = 1/(1-t)$ on $(-\infty, 1)$.

Proposition 27.14.5. *1. If φ, ψ are solutions on $[t_0, t_1]$ and $\|F(t, \varphi(t)) - F(t, \psi(t))\| \leq L\|\varphi(t) - \psi(t)\|$ for all t, then $\|\varphi(t) - \psi(t)\| \leq \|\varphi(t_0) - \psi(t_0)\|e^{L(t-t_0)}$.*

2. *(Linear equations) If $A\colon I \to M_n(\mathbb{R})$ and $b\colon I \to \mathbb{R}^n$ are continuous on an open interval I, the maximal solutions of $x' = A(t)x + b(t)$ are defined on all of I.*

Proof. (1) $u = \|\varphi - \psi\|$ satisfies $u(t) \le u(t_0) + L\int_{t_0}^{t} u$; apply Lemma 27.14.2. (2) On a compact subinterval $[c,d] \ni t_0$ with $\|A\| \le L$ and $\|b\| \le B$, $\|\varphi(t)\| \le \|\varphi(t_0)\| + B(d-c) + L\int \|\varphi\|$, so φ is bounded there by Grönwall, its graph stays in a compact set, and by Theorem 27.14.3(3) the maximal interval contains $[c,d]$. □

Theorem 27.14.6 (Smooth dependence)**.** *If F is C^k with $k \ge 1$, the* flow $\Phi(t, t_0, x_0)$*, the value at t of the maximal solution with $\varphi(t_0) = x_0$, is defined on an open subset of $\mathbb{R} \times D$ and is C^k there. Its derivative in x_0 solves the linearised equation $Y' = D_x F(t, \varphi(t))Y$, $Y(t_0) = 1$.*

This is [Har02, Chapter V]; see also [Lan93]. Continuity of Φ follows from Proposition 27.14.5(1) and the uniform δ in the proof of Theorem 27.14.3.

27.15 Stone–Weierstrass and Arzelà–Ascoli

Lemma 27.15.1. *The polynomials $p_0 = 0$, $p_{k+1}(t) = p_k(t) + (t^2 - p_k(t)^2)/2$ converge uniformly to $|t|$ on $[-1,1]$, and $p_k(0) = 0$.*

Proof. By induction $0 \le p_k(t) \le p_{k+1}(t) \le |t|$: indeed $|t| - p_{k+1} = (|t| - p_k)(1 - (|t| + p_k)/2)$ with $0 \le (|t|+p_k)/2 \le |t| \le 1$, and $p_{k+1} - p_k = (t^2 - p_k^2)/2 \ge 0$. Iterating, $0 \le |t| - p_k(t) \le |t|(1-|t|/2)^k$, and the maximum of $s(1 - s/2)^k$ on $[0,1]$ is at most $2/(k+1)$ (it is attained at $s = 2/(k+1)$ when $k \ge 1$). □

Theorem 27.15.2 (Stone–Weierstrass)**.** *Let K be a compact Hausdorff space and $\mathcal{A} \subseteq C(K, \mathbb{R})$ a subalgebra containing the constants and separating points. Then $\mathcal{A}$ is dense for the supremum norm. The same holds for $\mathcal{A} \subseteq C(K, \mathbb{C})$ if $\mathcal{A}$ is also closed under complex conjugation.*

Proof. The closure $\bar{\mathcal{A}}$ is a closed subalgebra. If $f \in \bar{\mathcal{A}}$ with $\|f\| \le c$, then $|f| = c \lim_k p_k(f/c) \in \bar{\mathcal{A}}$ by Lemma 27.15.1; hence $\max(f,g) = (f + g + |f - g|)/2$ and $\min(f,g)$ lie in $\bar{\mathcal{A}}$. For $x \ne y$ and reals α, β there is $h \in \mathcal{A}$ with $h(x) = \alpha$, $h(y) = \beta$ (take $h = \alpha + (\beta - \alpha)(u - u(x))/(u(y) - u(x))$ with u separating x and y).

Let $f \in C(K, \mathbb{R})$ and $\varepsilon > 0$. Fix x. For each y choose $h_y \in \mathcal{A}$ with $h_y(x) = f(x)$ and $h_y(y) = f(y)$; the open sets $\{h_y < f + \varepsilon\}$ cover K, and the minimum g_x of finitely many of these h_y lies in $\bar{\mathcal{A}}$, with $g_x(x) = f(x)$ and $g_x < f + \varepsilon$. The open sets $\{g_x > f - \varepsilon\}$ cover K, and the maximum g of finitely many g_x lies in $\bar{\mathcal{A}}$ and satisfies $\|g - f\| < \varepsilon$. For the complex case, the real parts $(f + \bar{f})/2$ of elements of $\mathcal{A}$ form a real subalgebra with the same properties, which is dense in $C(K, \mathbb{R})$; so $\mathcal{A}$ is dense in $C(K, \mathbb{C})$. □

Corollary 27.15.3. *Polynomials are dense in $C(K, \mathbb{R})$ for every compact $K \subseteq \mathbb{R}^n$, and trigonometric polynomials $\sum_{|k| \le N} c_k e^{2\pi i k t}$ are dense in the space of continuous functions $\mathbb{R} \to \mathbb{C}$ of period 1.*

Proof. The first statement is immediate. For the second, continuous functions of period 1 are continuous functions on $S^1 = \mathbb{R}/\mathbb{Z}$ (Theorem 27.7.3), and the polynomials in z and $\bar{z}$ restricted to S^1 form a conjugation-closed separating algebra; on S^1, $z^k \bar{z}^l = z^{k-l}$ corresponds to $e^{2\pi i (k-l) t}$. □

Theorem 27.15.4 (Arzelà–Ascoli)**.** *Let K be a compact Hausdorff space and $\mathcal{F} \subseteq C(K, \mathbb{R}^m)$ a family that is* equicontinuous *(for every x and $\varepsilon > 0$ there is a neighbourhood U of x with $\|f(x') - f(x)\| < \varepsilon$ for all $x' \in U$ and $f \in \mathcal{F}$) and pointwise bounded. Then $\mathcal{F}$ has compact closure in $C(K, \mathbb{R}^m)$ with the supremum metric.*

Proof. $C(K,\mathbb{R}^m)$ is complete, so by Theorem 18.7.4 it suffices to show that $\mathcal{F}$ is totally bounded. Let $\varepsilon > 0$. Choose finitely many points $x_1,\dots,x_k$ with neighbourhoods U_i as in the definition covering K. The set $\{(f(x_1),\dots,f(x_k)) : f \in \mathcal{F}\}$ is bounded in $\mathbb{R}^{mk}$, hence totally bounded, so there are $f_1,\dots,f_N \in \mathcal{F}$ such that every $f \in \mathcal{F}$ satisfies $\max_i \|f(x_i) - f_j(x_i)\| < \varepsilon$ for some j. For $x \in U_i$, $\|f(x) - f_j(x)\| \le \|f(x) - f(x_i)\| + \|f(x_i) - f_j(x_i)\| + \|f_j(x_i) - f_j(x)\| < 3\varepsilon$. □

27.16 Exercises

Exercise 27.16.1. Show that $e = \exp(1)$ is irrational.

Solution. If $e = p/q$, then $x = q!(e - \sum_{k\le q} 1/k!)$ is a positive integer, but $x = \sum_{k>q} q!/k! < \sum_{j\ge1}(q+1)^{-j} = 1/q \le 1$. □

Exercise 27.16.2. Show that $\sum 1/n$ diverges while $\sum(-1)^n/n$ converges, and that the latter series can be rearranged to converge to any given real number.

Solution. $\sum_{2^j<n\le2^{j+1}} 1/n \ge 1/2$, so the partial sums are unbounded; the alternating series converges by Lemma 27.5.7. For a target c, add positive terms $1/(2k)$ until the partial sum exceeds c, then negative terms until it is below c, and so on; since both the positive and the negative parts diverge and the terms tend to 0, the partial sums converge to c. This is the special case $\alpha = \beta = c$ of Theorem 27.5.9, where the details are written out. □

Exercise 27.16.3. Let $\sum_n a_n$ be a convergent series of real numbers and $\sigma\colon \mathbb{N} \to \mathbb{N}$ a bijection that moves every index by a bounded amount: $|\sigma(n) - n| \le K$ for all n. Show that $\sum_n a_{\sigma(n)}$ converges to the same sum. Deduce that the rearrangement of Example 27.5.11(1) moves some indices arbitrarily far.

Solution. Let $S_N = \sum_{n\le N} a_n$ and $T_N = \sum_{n\le N} a_{\sigma(n)} = \sum_{m\in\sigma(\{0,\dots,N\})} a_m$. If $m \le N - K$, then $\sigma^{-1}(m) \le m + K \le N$, so $m \in \sigma(\{0,\dots,N\})$; and every $m \in \sigma(\{0,\dots,N\})$ satisfies $m \le N + K$. So $\{0,\dots,N\}$ and $\sigma(\{0,\dots,N\})$ differ only in indices between $N - K$ and $N + K$, and $|T_N - S_N| \le \sum_{N-K<m\le N+K} |a_m|$, a sum of at most $2K$ terms, which tends to 0 as $a_m \to 0$. Hence $T_N - S_N \to 0$. The rearrangement of the example changes the sum, so it cannot move indices by a bounded amount; indeed its $3m$-th term is $-1/(4m)$, the $4m$-th term of S, moved by m places. □

Exercise 27.16.4. Show that $f_n(x) = \sqrt{x^2 + 1/n}$ are smooth and converge uniformly on $\mathbb{R}$ to $|x|$, which is not differentiable. Prove that if $f_n \to f$ pointwise and $f_n' \to g$ uniformly on an interval, with f_n continuously differentiable, then f is differentiable with $f' = g$.

Solution. $0 \le \sqrt{x^2+1/n} - |x| = \frac{1/n}{\sqrt{x^2+1/n}+|x|} \le 1/\sqrt{n}$. For the second part, $f_n(x) = f_n(a) + \int_a^x f_n'$ converges to $f(a) + \int_a^x g$, so $f(x) = f(a) + \int_a^x g$ and Theorem 27.8.3 applies. □

Exercise 27.16.5. Show that $(r,\theta) \mapsto (r\cos\theta, r\sin\theta)$ is a local diffeomorphism $(0,\infty)\times\mathbb{R} \to \mathbb{R}^2 \setminus \{0\}$, but not injective, and compute its Jacobian determinant.

Exercise 27.16.6. (Peano's theorem.) Show that if F is only continuous, $x' = F(t,x)$ still has local solutions, by applying the Arzelà–Ascoli theorem to the Euler polygons φ_k with step $1/k$.

Exercise 27.16.7. Show that a compact subset of $C(K,\mathbb{R}^m)$ is equicontinuous and pointwise bounded.

Exercise 27.16.8. Compute $\lim_n \frac{n^2+1}{2n^2-n}$, $\lim_n(\sqrt{n^2+n} - n)$ and $\lim_n(2^n + 3^n)^{1/n}$.

Solution. Dividing by n^2, the first is $\frac{1+1/n^2}{2-1/n} \to \frac{1}{2}$. For the second, $\sqrt{n^2+n}-n = \frac{n}{\sqrt{n^2+n}+n} = \frac{1}{\sqrt{1+1/n}+1} \to \frac{1}{2}$. For the third, $3 \le (2^n+3^n)^{1/n} \le (2\cdot 3^n)^{1/n} = 3\cdot 2^{1/n} \to 3$ (Proposition 27.2.9(2)), so the limit is 3 by the squeeze theorem. □

Exercise 27.16.9. Show that $\limsup_n a_n$ is the largest element of $\bar{\mathbb{R}}$ that is a limit of a subsequence of (a_n), and $\liminf_n a_n$ the smallest.

Solution. Let $S_n = \sup_{k \ge n} a_k$, a decreasing sequence with limit $L = \limsup a_n$ (Proposition 27.2.10). If $a_{n_k} \to \ell$, then $a_{n_k} \le S_n$ for $n_k \ge n$, so $\ell \le S_n$ for all n, and $\ell \le L$. Conversely, if $L \in \mathbb{R}$, choose recursively $n_k > n_{k-1}$ with $S_{n_{k-1}+1} - \frac{1}{k} < a_{n_k} \le S_{n_{k-1}+1}$; both bounds tend to L, so $a_{n_k} \to L$ by the squeeze theorem. If $L = +\infty$ the sequence is unbounded above and Theorem 27.2.12 applies; if $L = -\infty$ then $a_n \le S_n \to -\infty$. The statement for lim inf follows by passing to $(-a_n)$. □

Exercise 27.16.10. Show that $f(x) = x\mathbf{1}_{\mathbb{Q}}(x)$ is continuous at 0 and discontinuous at every $a \neq 0$.

Solution. $|f(x)| \le |x|$, so $f(x) \to 0 = f(0)$ as $x \to 0$. For $a \neq 0$, choose rational $x_n \to a$ and irrational $y_n \to a$ (Counterexample 27.3.10); then $f(x_n) = x_n \to a$ and $f(y_n) = 0$, so f has no limit at a (Theorem 27.3.4), in particular it is not continuous there. □

Exercise 27.16.11. Let $f : \mathbb{R} \to \mathbb{R}$ be continuous with $f(x+y) = f(x)+f(y)$ for all x, y. Show that $f(x) = cx$ with $c = f(1)$.

Solution. $f(0) = f(0)+f(0)$ gives $f(0) = 0$, then $f(-x) = -f(x)$, and by induction $f(nx) = nf(x)$ for $n \in \mathbb{N}$, hence for $n \in \mathbb{Z}$. For $x = p/q$ with $q \ge 1$, $qf(p/q) = f(p) = pc$, so $f(x) = cx$ on $\mathbb{Q}$. For real x, choose rational $x_n \to x$ (density of $\mathbb{Q}$); by continuity $f(x) = \lim f(x_n) = \lim cx_n = cx$. □

Exercise 27.16.12. Show that a continuous periodic function $f : \mathbb{R} \to \mathbb{R}$ is bounded and uniformly continuous.

Solution. Let $p > 0$ be a period. On $[0, 2p]$, f is bounded and uniformly continuous (Theorem 27.4.10 and Proposition 27.4.13(3)), and every value of f is taken on $[0, p]$. Given ε, let $\delta < p$ work on $[0, 2p]$. If $|x-y| < \delta$, translating both by the same multiple of p we may assume $0 \le \min(x, y) < p$, and then $x, y \in [0, 2p]$, so $|f(x) - f(y)| < \varepsilon$. □

Exercise 27.16.13. Show that $n(a^{1/n}-1) \to \log a$ for every $a > 0$.

Solution. Let $t = \log a$, so $a^{1/n} = e^{t/n}$. If $t = 0$ both sides vanish. Otherwise $n(e^{t/n}-1) = t \cdot \frac{e^{t/n}-1}{t/n} \to t$ by Proposition 27.7.5(1) and Theorem 27.3.4, since $t/n \to 0$ and $t/n \neq 0$. □

Exercise 27.16.14. Compute $\int_0^{\pi} x^2 \sin x \, dx$, and show by integration by parts and induction on n that $\int_0^1 x^m(1-x)^n \, dx = \frac{m!\,n!}{(m+n+1)!}$ for integers $m, n \ge 0$.

Solution. Twice by parts: $\int_0^{\pi} x^2 \sin x \, dx = [-x^2\cos x]_0^{\pi} + 2\int_0^{\pi} x\cos x \, dx = \pi^2 + 2\big([x\sin x]_0^{\pi} - \int_0^{\pi} \sin x \, dx\big) = \pi^2 + 2(0-2) = \pi^2 - 4$. For the second, let $B(m, n)$ be the integral. For $n \ge 1$, take $f(x) = x^{m+1}/(m+1)$ and $g(x) = (1-x)^n$; the boundary term vanishes at both ends, and $B(m, n) = \frac{n}{m+1} B(m+1, n-1)$. Iterating, $B(m, n) = \frac{n(n-1)\cdots 1}{(m+1)(m+2)\cdots(m+n)} B(m+n, 0)$, and $B(m+n, 0) = \frac{1}{m+n+1}$, which gives $\frac{m!\,n!}{(m+n+1)!}$. □

Exercise 27.16.15. Let $f : I \to \mathbb{R}$ be continuous on an interval and *midpoint convex*: $f(\frac{x+y}{2}) \le \frac{f(x)+f(y)}{2}$ for all $x, y \in I$. Show that f is convex. (Without continuity this fails: a $\mathbb{Q}$-linear map $\mathbb{R} \to \mathbb{R}$ that is not $\mathbb{R}$-linear, which exists by choosing a basis of $\mathbb{R}$ over $\mathbb{Q}$, is midpoint affine but not convex.)

Solution. By induction on k, $f(\sum_i x_i/2^k) \le \sum_i f(x_i)/2^k$ for 2^k points $x_i \in I$ (split them into two halves and apply midpoint convexity to the two averages). Given x, y and a dyadic $t = j/2^k \in [0,1]$, take j copies of x and $2^k - j$ copies of y: $f(tx + (1-t)y) \le t f(x) + (1-t) f(y)$. Dyadic numbers are dense in $[0,1]$, and both sides are continuous in t, so the inequality holds for all $t \in [0,1]$. □

Exercise 27.16.16. Decide whether the following series converge: $\sum_{n\ge1} \frac{n^n}{n!\,3^n}$, $\sum_{n\ge2} \frac{1}{(\log n)^{\log n}}$, $\sum_{n\ge1} \left(1 - \frac{1}{n}\right)^{n^2}$, $\sum_{n\ge2} \frac{(-1)^n}{\sqrt{n}+(-1)^n}$.

Solution. (1) The ratio is $\frac{1}{3}(1+\frac{1}{n})^n \to \frac{e}{3} < 1$: converges. (2) $(\log n)^{\log n} = n^{\log\log n} \ge n^2$ once $\log\log n \ge 2$, so it converges by comparison with $\sum n^{-2}$. (3) The n-th root is $(1-\frac{1}{n})^n \to e^{-1} < 1$: converges. (4) $\frac{(-1)^n}{\sqrt{n}+(-1)^n} = \frac{(-1)^n}{\sqrt{n}} - \frac{1}{\sqrt{n}(\sqrt{n}+(-1)^n)}$; the first series converges (alternating), the second diverges by limit comparison with $\sum \frac{1}{n}$; so the series diverges, although its terms are alternating and tend to 0 (they are not monotone in absolute value). □

Exercise 27.16.17. Find the largest volume of a box with edges parallel to the coordinate axes inscribed in the ellipsoid $x^2/a^2 + y^2/b^2 + z^2/c^2 = 1$ ($a, b, c > 0$).

Solution. A vertex (x, y, z) with $x, y, z > 0$ on the ellipsoid determines the box, of volume $V = 8xyz$. The volume is a continuous function on the compact part of the ellipsoid with $x, y, z \ge 0$, positive somewhere and zero when a coordinate vanishes, so its maximum is attained with $x, y, z > 0$, where $\nabla h = (2x/a^2, 2y/b^2, 2z/c^2) \ne 0$. Theorem 27.13.6 gives $8yz = 2\lambda x/a^2$, $8xz = 2\lambda y/b^2$, $8xy = 2\lambda z/c^2$. Multiplying by x, y, z respectively, $x^2/a^2 = y^2/b^2 = z^2/c^2 = 4xyz/\lambda$, and the constraint makes each equal to $\frac{1}{3}$. So $(x, y, z) = (a, b, c)/\sqrt{3}$ and the maximal volume is $8abc/(3\sqrt{3})$, a fraction $2/(\sqrt{3}\pi) \approx 0.37$ of the volume $\frac{4}{3}\pi abc$ of the ellipsoid. □

Exercise 27.16.18. Find the points of the hyperbola $xy = 1$ nearest to the origin, and confirm with Example 27.13.12 that they are strict local minima of the distance.

Solution. Minimise $f = x^2 + y^2$ on $M = \{h = 0\}$, $h = xy - 1$; M is closed and $f \to \infty$ along M, so a minimum exists, and $\nabla h = (y, x) \ne 0$ on M. The equations $2x = \lambda y$, $2y = \lambda x$ give $2x^2 = \lambda xy = 2y^2$, so $y = \pm x$, and $xy = 1$ forces $y = x = \pm 1$, with $\lambda = 2$: the nearest points are $\pm(1,1)$, at distance $\sqrt{2}$. With $L = x^2 + y^2 - 2(xy - 1)$, $L_{xx} = L_{yy} = 2$, $L_{xy} = -2$, and at $(1,1)$, $(h_x, h_y) = (1,1)$; the bordered determinant is $-(L_{xx} - 2L_{xy} + L_{yy}) = -8 < 0$, a strict local minimum. Note that $D^2 f = 2I$ alone would also suggest a minimum here, but $D^2 L$ is only semidefinite on $\mathbb{R}^2$; its restriction to the tangent line $\mathbb{R}(-1,1)$ is what counts. □

Exercise 27.16.19. Prove *Hadamard's inequality*: for a real $n \times n$ matrix A with columns $a_1, \dots, a_n$, $|\det A| \le \|a_1\| \cdots \|a_n\|$, with equality for nonzero columns exactly when the columns are pairwise orthogonal. (Geometrically: among parallelepipeds with given edge lengths, the rectangular box has the largest volume.) Hint: maximise det on the set of matrices with unit columns.

Solution. If a column vanishes both sides are 0; otherwise divide each column by its length, which divides both sides by $\prod_j \|a_j\|$. So we must show $\det A \le 1$ when all $\|a_j\| = 1$. The

set S of such matrices is compact in $\mathbb{R}^{n^2}$, so det has a maximum on S at some A, and the maximum is $\geq \det I = 1 > 0$. The constraints $h_j(A) = \|a_j\|^2 - 1$ have gradients $2a_j$ placed in the j-th block of coordinates, which are nonzero and lie in different blocks, hence are independent. Expanding along the j-th column, $\partial \det/\partial a_{ij} = C_{ij}$, the (i,j) cofactor (Proposition 11.5.3). Theorem 27.13.6 gives $C_{ij} = 2\lambda_j a_{ij}$, that is, $C = 2A\Lambda$ with $\Lambda = \operatorname{diag}(\lambda_j)$ and $C = (C_{ij})$. Since $\det A \neq 0$, the adjugate formula $A\,C^T = \det(A)\,I$ gives $C = \det(A)(A^{-1})^T$, so $\det(A)\,I = A^T C = 2A^T A\Lambda$. Hence Λ is invertible and $A^T A = \det(A)(2\Lambda)^{-1}$ is diagonal: the columns of A are orthogonal unit vectors, A is orthogonal, and $\det A = 1$ at the maximum. For the equality case, if the columns are orthogonal, $|\det A|^2 = \det(A^T A) = \prod_j \|a_j\|^2$; conversely, equality means that the normalised matrix (with columns $a_j/\|a_j\|$, possibly after changing the sign of one column) is a maximum point, hence has orthogonal columns by the argument above. □

Exercise 27.16.20. Let $y \in \mathbb{R}^n$. Show that the point of the simplex $\Delta = \{x \in \mathbb{R}^n : x_i \geq 0, \sum_i x_i = 1\}$ nearest to y is $x_i = \max(0, y_i - \tau)$, where τ is the unique number with $\sum_i \max(0, y_i - \tau) = 1$. Compute it for $y = (0.8, 0.6, -0.5)$.

Solution. Minimise the strictly convex function $f(x) = \frac{1}{2}\|x - y\|^2$ subject to $g_i = -x_i \leq 0$ and $h = \sum_i x_i - 1 = 0$. The conditions (27.6) read $x_i - y_i - \mu_i + \lambda = 0$, $\mu_i \geq 0$, $\mu_i x_i = 0$. If $x_i > 0$ then $x_i = y_i - \lambda$; if $x_i = 0$ then $y_i - \lambda = -\mu_i \leq 0$. In both cases $x_i = \max(0, y_i - \lambda)$, and $\sum_i x_i = 1$ determines $\lambda = \tau$: the function $t \mapsto \sum_i \max(0, y_i - t)$ is continuous, decreasing, strictly so where positive, equal to 0 for $t \geq \max_i y_i$ and tending to ∞ as $t \to -\infty$. Conversely, this x with $\mu_i = \max(0, \tau - y_i)$ satisfies the conditions, so it is the unique minimum by Theorem 27.13.18 (like the water-filling of Example 27.13.19, with the vessel upside down). For $y = (0.8, 0.6, -0.5)$, trying $x_3 = 0$: $(0.8 - \tau) + (0.6 - \tau) = 1$ gives $\tau = 0.2$, and indeed $-0.5 - 0.2 < 0$; so $x = (0.6, 0.4, 0)$. □

Exercise 27.16.21. Show that the astroid $\gamma(t) = (\cos^3 t, \sin^3 t)$, $t \in [0, 2\pi]$, has length 6, and that it is not regular.

Solution. $\gamma'(t) = (-3\cos^2 t \sin t, 3\sin^2 t \cos t)$, so $|\gamma'(t)| = 3|\sin t \cos t|\sqrt{\cos^2 t + \sin^2 t} = 3|\sin t \cos t|$, which vanishes at the multiples of $\pi/2$ (the four cusps). By symmetry $L(\gamma) = 4\int_0^{\pi/2} 3\sin t \cos t\, dt = 4 \cdot \frac{3}{2}\left[\sin^2 t\right]_0^{\pi/2} = 6$. □

Exercise 27.16.22. Let $\cosh x = \frac{1}{2}(e^x + e^{-x})$ and $\sinh x = \frac{1}{2}(e^x - e^{-x})$. Show that the graph of cosh over $[0, a]$ has length $\sinh a$.

Solution. $\cosh' = \sinh$, $\sinh' = \cosh$ and $\cosh^2 - \sinh^2 = 1$, so $\sqrt{1 + \sinh^2 x} = \cosh x$ (which is positive), and $\int_0^a \cosh x\, dx = \sinh a$ by Example 27.11.5(2) and the fundamental theorem of calculus. □

Exercise 27.16.23. Let $\gamma(t) = e^{-t}(\cos t, \sin t)$ for $t \geq 0$. Show that $\gamma|_{[0,T]}$ has length $\sqrt{2}(1 - e^{-T})$. So the logarithmic spiral winds infinitely often around the origin but has finite total length $\sqrt{2}$.

Solution. $\gamma'(t) = e^{-t}(-\cos t - \sin t, \cos t - \sin t)$, and $|\gamma'(t)|^2 = e^{-2t}\big((\cos t + \sin t)^2 + (\cos t - \sin t)^2\big) = 2e^{-2t}$. Hence $L = \int_0^T \sqrt{2}e^{-t}\, dt = \sqrt{2}(1 - e^{-T})$. □

Exercise 27.16.24. Show that the Newtonian field $F(x) = -x/|x|^3$ on $\mathbb{R}^3 \setminus \{0\}$ is the gradient of $g(x) = 1/|x|$, and compute the work $\int_\gamma F \cdot d\gamma$ along any piecewise C^1 curve in $\mathbb{R}^3 \setminus \{0\}$ from a point at distance r_1 from the origin to a point at distance r_2.

Solution. $\partial_j |x|^{-1} = -\frac{1}{2}(x_1^2 + x_2^2 + x_3^2)^{-3/2} \cdot 2x_j = -x_j/|x|^3$. By Proposition 27.11.13(5) the work is $g(\gamma(b)) - g(\gamma(a)) = 1/r_2 - 1/r_1$, whatever the path; it is positive when the particle falls towards the origin, $r_2 < r_1$. □

Chapter 28

Measure and Integration

28.1 Introduction

The Lebesgue integral extends the Riemann integral to a class of functions that is closed under the limits needed in analysis: the monotone and dominated convergence theorems (Theorems 28.4.3 and 28.4.8) and the completeness of the spaces L^p (Theorem 28.5.3) are the basis of the functional analysis used to prove the Hodge theorem. This chapter constructs Lebesgue measure, proves the convergence theorems, Littlewood's three principles (approximation of sets by boxes, Lusin's theorem, Egorov's theorem), the Lebesgue differentiation theorem with its consequences (the density theorem and the fundamental theorem of calculus for Lebesgue integrals, with the Cantor function as a counterexample), independence and the two Borel–Cantelli lemmas, with applications to the digits of random numbers and Borel's normal number theorem (Theorem 28.7.9), Fubini's theorem with the layer cake formula and the Hardy–Littlewood maximal theorem, the change of variables formula with Cavalieri's principle, volumes of solids of revolution and the theorems of Pappus–Guldin, the Radon–Nikodym theorem, and the characterisation of indefinite integrals as the absolutely continuous functions. It then treats Radon measures as positive linear functionals (the Riesz–Markov theorem, Theorem 28.14.6, and its version for signed and vector-valued functionals, Theorem 28.14.9), weak convergence of measures and its compactness theorem, and the differentiation of measures with respect to Lebesgue measure, with Lebesgue's theorem on the differentiability of monotone functions. It ends with an introduction to geometric measure theory: Hausdorff measures and Hausdorff dimension (with the Cantor set as example), box-counting dimension and self-similar sets such as the Sierpiński gasket and the Koch curve, whose dimension is computed by Moran's equation (Theorem 28.18.10), Rademacher's theorem on the differentiability of Lipschitz maps, the area formula, which computes the k-dimensional measure of parametrised sets, the coarea formula with integration in polar coordinates, and densities and rectifiable sets (Sections 28.17–28.22). References: [Rud87] and [Fol99].

Prerequisites. Chapter 27 (Real Analysis).

On the way to the Hodge conjecture. The direct route needs measures, Lebesgue measure and the integral, L^p spaces, product measures and Fubini's theorem, and the change of variables formula (Sections 28.2 to 28.5, 28.10, 28.11). The remaining sections, from the modes of convergence to Radon measures, Hausdorff measures, self-similar sets, the area and coarea formulas and densities, develop measure theory and geometric measure theory for their own sake.

We use the extended half-line $[0, \infty]$ with $a + \infty = \infty$ and $0 \cdot \infty = 0$.

28.2 Measures

Why σ-algebras. We want to assign a size to subsets of $\mathbb{R}$ extending the length of intervals, additive on disjoint sets, and invariant under translation. Two features of the definition below need explanation. First, additivity is required for *countable* disjoint unions, not only finite ones: this is what makes limits work (the convergence theorems of Section 28.4), and it is natural, since for instance $[0,1) = \bigsqcup_n [1-2^{-n}, 1-2^{-n-1})$ should have length $\sum_n 2^{-n-1} = 1$. Second, the size is defined only on a family of "measurable" sets, not on all subsets: by the Vitali construction (Counterexample 28.3.7) there is no countably additive, translation invariant length defined on all subsets of $\mathbb{R}$. The family of measurable sets must be closed under the operations used in analysis, complements and countable unions; this is a σ-algebra.

Definition 28.2.1. A *σ-algebra* on a set X is a set $\mathcal{A}$ of subsets containing X and closed under complements and countable unions. The σ-algebra *generated* by a family of subsets is the intersection of all σ-algebras containing it; for a topological space, the *Borel* σ-algebra $\mathcal{B}(X)$ is generated by the open sets. A *measure* on $(X, \mathcal{A})$ is a map $\mu\colon \mathcal{A} \to [0,\infty]$ with $\mu(\emptyset) = 0$ and $\mu(\bigsqcup_k A_k) = \sum_k \mu(A_k)$ for countable disjoint families. It is *finite* if $\mu(X) < \infty$, *σ-finite* if X is a countable union of sets of finite measure, and *complete* if subsets of measure zero sets are measurable. A property holds *almost everywhere* (a.e.) if it holds outside a set of measure zero.

Example 28.2.2.

1. On any set X, $\{\emptyset, X\}$ and the power set $\mathcal{P}(X)$ are σ-algebras, the smallest and the largest. If $X = A_1 \sqcup \cdots \sqcup A_k$ is a finite partition, the unions of some of the A_i form a σ-algebra with 2^k elements; on a finite set every σ-algebra is of this form, generated by its minimal nonempty members.

2. The sets that are countable or have countable complement form a σ-algebra on any set: complements exchange the two kinds, and a countable union is countable unless one of the sets is cocountable, in which case the union is cocountable. On $\mathbb{R}$ it is strictly smaller than the Borel σ-algebra, since $[0,1]$ is neither countable nor cocountable.

3. The Borel σ-algebra of $\mathbb{R}$ contains the open sets, the closed sets, the countable unions of closed sets (such as $\mathbb{Q}$ or $[0,1)$) and the countable intersections of open sets (such as $\mathbb{R} \setminus \mathbb{Q}$), and much more; it is generated already by the intervals (a,b), or by the rays (a,∞).

Example 28.2.3.

1. *Counting measure* on $\mathcal{P}(X)$: $\mu(A)$ is the number of elements of A, or ∞. It is σ-finite if and only if X is countable.

2. *Dirac measure* at x: $\delta_x(A) = 1$ if $x \in A$ and 0 otherwise; more generally $\sum_i c_i \delta_{x_i}$ with $c_i \geq 0$, a *discrete* measure. A fair die is the probability measure $\frac{1}{6}\sum_{k=1}^{6} \delta_k$ on $\{1,\dots,6\}$, and the probability of an even result is $\mu(\{2,4,6\}) = \frac{1}{2}$.

3. If μ is a measure and E a measurable set, $\mu_E(A) = \mu(A \cap E)$ is a measure, the restriction of μ to E; and if $f \geq 0$ is measurable, $A \mapsto \int_A f\, d\mu$ is a measure (Section 28.4), the measure with *density* f.

4. Lebesgue measure on $\mathbb{R}^n$ (Section 28.3), which assigns to boxes their volume.

Countable additivity forces continuity properties that finite additivity does not give (Proposition 28.2.4 below). For instance, for counting measure on $\mathbb{N}$ the sets $A_n = \{n, n+1, \dots\}$ decrease to $\emptyset$ while $\mu(A_n) = \infty$ for all n: the hypothesis $\mu(A_1) < \infty$ in continuity from above cannot be dropped.

Proposition 28.2.4. *Let μ be a measure. If $A \subseteq B$, then $\mu(A) \leq \mu(B)$; $\mu(\bigcup_k A_k) \leq \sum_k \mu(A_k)$; if $A_1 \subseteq A_2 \subseteq \cdots$, then $\mu(\bigcup_k A_k) = \lim_k \mu(A_k)$; and if $A_1 \supseteq A_2 \supseteq \cdots$ with $\mu(A_1) < \infty$, then $\mu(\bigcap_k A_k) = \lim_k \mu(A_k)$.*

Proof. $\mu(B) = \mu(A) + \mu(B \setminus A)$. Replacing A_k by $A_k \setminus \bigcup_{j<k} A_j$ gives disjoint sets with the same union and smaller measures. For increasing sets, $\bigcup_k A_k = \bigsqcup_k (A_k \setminus A_{k-1})$, and the partial sums of the measures are $\mu(A_k)$. For decreasing sets apply this to $A_1 \setminus A_k$. □

Definition 28.2.5. A map $f : (X, \mathcal{A}) \to (Y, \mathcal{B})$ is *measurable* if $f^{-1}(B) \in \mathcal{A}$ for $B \in \mathcal{B}$. Functions to $[-\infty, \infty]$, $\mathbb{R}$ or $\mathbb{C}$ are measurable for the Borel σ-algebras. A *simple function* is a finite combination $\sum_i a_i \mathbf{1}_{A_i}$ of indicator functions of measurable sets.

Measurability of functions is the condition that makes integrals of f meaningful: one needs to measure the sets $\{a < f \leq b\}$, on which f is approximately constant. Continuous functions on a topological space are Borel measurable, since preimages of open sets are open; monotone functions on $\mathbb{R}$ are Borel measurable, since $\{f > a\}$ is an interval; and an indicator function $\mathbf{1}_A$ is measurable if and only if A is measurable, since $\{\mathbf{1}_A > a\}$ is $\emptyset$, A or X.

Proposition 28.2.6.

1. *$f : X \to [-\infty, \infty]$ is measurable if and only if $\{f > a\}$ is measurable for all $a \in \mathbb{R}$.*
2. *If $f_1, \ldots, f_k : X \to \mathbb{R}$ are measurable and $\Phi : \mathbb{R}^k \to \mathbb{R}$ is continuous, $\Phi(f_1, \ldots, f_k)$ is measurable; so sums and products of measurable functions are measurable, and $f : X \to \mathbb{C}$ is measurable if and only if its real and imaginary parts are.*
3. *Pointwise* sup, inf, lim sup *and* lim inf *of sequences of measurable functions are measurable.*
4. *Every measurable $f : X \to [0, \infty]$ is the pointwise limit of an increasing sequence of simple functions $0 \leq s_1 \leq s_2 \leq \cdots$.*

Proof. (1) The sets $(a, \infty]$ generate the Borel σ-algebra of $[-\infty, \infty]$, and the sets B with $f^{-1}(B)$ measurable form a σ-algebra. (2) Open subsets of $\mathbb{R}^k$ are countable unions of products of open intervals, and $(f_1, \ldots, f_k)^{-1}$ of such a product is a finite intersection of measurable sets; so $(f_1, \ldots, f_k)$ is measurable for Borel sets, and so is its composite with Φ. (3) $\{\sup_n f_n > a\} = \bigcup_n \{f_n > a\}$, $\inf_n f_n = -\sup_n(-f_n)$, and $\limsup f_n = \inf_n \sup_{k \geq n} f_k$. (4) Let $s_n = \min(n, 2^{-n} \lfloor 2^n f \rfloor)$. □

28.3 Outer measures and Lebesgue measure

Definition 28.3.1. An *outer measure* on X is a map $\mu^* : \mathcal{P}(X) \to [0, \infty]$ with $\mu^*(\emptyset) = 0$, monotone and countably subadditive. A set A is *μ^*-measurable* if $\mu^*(E) = \mu^*(E \cap A) + \mu^*(E \setminus A)$ for all $E \subseteq X$.

Theorem 28.3.2 (Carathéodory)**.** *The μ^*-measurable sets form a σ-algebra $\mathcal{M}$, and $\mu^*|_{\mathcal{M}}$ is a complete measure.*

Proof. By subadditivity, A is measurable if and only if $\mu^*(E \cap A) + \mu^*(E \setminus A) \leq \mu^*(E)$ for all E. The definition is symmetric in A and $X \setminus A$. For measurable A, B and any E,

$$\mu^*(E \cap (A \cup B)) + \mu^*(E \setminus (A \cup B)) \leq \mu^*(E \cap A) + \mu^*((E \setminus A) \cap B) + \mu^*((E \setminus A) \setminus B) = \mu^*(E \cap A) + \mu^*(E \setminus A) = \mu^*(E),$$

so $\mathcal{M}$ is closed under finite unions. Let $A_1, A_2, \ldots \in \mathcal{M}$ be disjoint, $B_n = A_1 \cup \cdots \cup A_n$ and $B = \bigcup_n A_n$. Measurability of A_n gives $\mu^*(E \cap B_n) = \mu^*(E \cap A_n) + \mu^*(E \cap B_{n-1})$, so $\mu^*(E \cap B_n) = \sum_{j \leq n} \mu^*(E \cap A_j)$, and $\mu^*(E) = \mu^*(E \cap B_n) + \mu^*(E \setminus B_n) \geq \sum_{j \leq n} \mu^*(E \cap A_j) + \mu^*(E \setminus B)$.

Letting $n \to \infty$ and using subadditivity, $\mu^*(E) \geq \sum_j \mu^*(E \cap A_j) + \mu^*(E \setminus B) \geq \mu^*(E \cap B) + \mu^*(E \setminus B)$. So $B \in \mathcal{M}$, and $E = B$ gives countable additivity. General countable unions reduce to disjoint ones. If $\mu^*(A) = 0$, then $\mu^*(E \cap A) + \mu^*(E \setminus A) \leq \mu^*(E)$, so A is measurable. □

Definition 28.3.3. A *box* in $\mathbb{R}^n$ is a product $Q = \prod_i [a_i, b_i]$ with volume $v(Q) = \prod_i (b_i - a_i)$. The *Lebesgue outer measure* of $A \subseteq \mathbb{R}^n$ is $\lambda^*(A) = \inf\{\sum_k v(Q_k) : A \subseteq \bigcup_k Q_k\}$, the infimum over countable covers by boxes. The λ^*-measurable sets are *Lebesgue measurable*, and $\lambda = \lambda^n$ is *Lebesgue measure*.

Theorem 28.3.4. *λ^* is an outer measure, and $\lambda^*(Q) = v(Q)$ for boxes. Every Borel set is Lebesgue measurable, so λ is a complete measure on a σ-algebra containing $\mathcal{B}(\mathbb{R}^n)$. It is translation invariant and* regular*: for measurable E, $\lambda(E) = \inf\{\lambda(U) : U \supseteq E \text{ open}\} = \sup\{\lambda(K) : K \subseteq E \text{ compact}\}$.*

Proof. Countable subadditivity: given covers of A_k with total volume $\leq \lambda^*(A_k) + \varepsilon 2^{-k}$, their union covers $\bigcup_k A_k$.

Volume of a box. Clearly $\lambda^*(Q) \leq v(Q)$. Let $Q \subseteq \bigcup_k Q_k$ and $\varepsilon > 0$. Enlarge each Q_k to a box Q_k' whose interior contains Q_k, with $v(Q_k') \leq v(Q_k) + \varepsilon 2^{-k}$. By compactness finitely many interiors cover Q, say those of $Q_1', \ldots, Q_N'$. The endpoints of Q and of the Q_k' in each coordinate define a grid dividing Q into boxes C with disjoint interiors, and $v(Q) = \sum_C v(C)$ (volume is multiplicative and length is additive). The centre of each C lies in some Q_k', and then $C \subseteq Q_k'$ because no grid line crosses the interior of C. The cells contained in Q_k' have disjoint interiors, so their volumes add up to at most $v(Q_k')$. Hence $v(Q) \leq \sum_k v(Q_k') \leq \sum_k v(Q_k) + \varepsilon$.

Borel sets. The half-spaces $H = \{x_i \leq c\}$ generate $\mathcal{B}(\mathbb{R}^n)$, since open sets are countable unions of boxes with rational vertices. Given E and a cover by boxes Q_k with $\sum v(Q_k) \leq \lambda^*(E) + \varepsilon$, the boxes $Q_k \cap H$ and $Q_k \cap \{x_i \geq c\}$ cover $E \cap H$ and $E \setminus H$ and have total volume $\sum_k v(Q_k)$. So $\lambda^*(E \cap H) + \lambda^*(E \setminus H) \leq \lambda^*(E) + \varepsilon$, and H is measurable by Theorem 28.3.2.

Invariance and regularity. Translation maps boxes to boxes of the same volume. Enlarging the covering boxes slightly into open boxes gives outer regularity. For inner regularity, first let E be bounded, contained in a closed box Q. Given ε, choose open $U \supseteq Q \setminus E$ with $\lambda(U) \leq \lambda(Q \setminus E) + \varepsilon$; then $K = Q \setminus U \subseteq E$ is compact with $\lambda(E \setminus K) \leq \lambda(U \setminus (Q \setminus E)) \leq \varepsilon$. For general E, apply this to $E \cap [-m, m]^n$ and use continuity from below. □

Definition 28.3.5. Let μ be a measure on the Borel sets of a topological space X (or on a σ-algebra containing them). It is *locally finite* if every point has a neighbourhood of finite measure; *outer regular* if $\mu(E) = \inf\{\mu(U) : U \supseteq E \text{ open}\}$, *inner regular* if $\mu(E) = \sup\{\mu(K) : K \subseteq E \text{ compact}\}$, for all measurable E, and *regular* if it is both. A locally finite regular measure on a locally compact Hausdorff space is a *Radon measure*.

Example 28.3.6. Lebesgue measure is locally finite and regular (Theorem 28.3.4), so it is a Radon measure, and so is a Dirac measure δ_x. Counting measure on $\mathbb{Z}$ is Radon, but counting measure on $\mathbb{R}$ is neither locally finite nor outer regular: $\{0\}$ has measure 1, while every open set containing 0 is infinite and has measure ∞. The 1-dimensional Hausdorff measure on $\mathbb{R}^2$ (Section 28.17) is not locally finite either, since every open set has infinite length.

Counterexample 28.3.7. There are subsets of $\mathbb{R}$ that are not Lebesgue measurable. Choose (by the axiom of choice) a set $V \subseteq [0, 1]$ containing exactly one element of each class of $\mathbb{R}/\mathbb{Q}$. The translates $V + q$, $q \in \mathbb{Q} \cap [-1, 1]$, are disjoint and their union lies between $[0, 1]$ and $[-1, 2]$. If V were measurable, translation invariance and countable additivity would give $1 \leq \sum_q \lambda(V) \leq 3$, which is impossible whether $\lambda(V) = 0$ or $\lambda(V) > 0$.

Proposition 28.3.8. *Let F be the free group on two generators a, b (Chapter 7), and for $x \in \{a, a^{-1}, b, b^{-1}\}$ let $W(x)$ be the set of reduced words beginning with x. Then*

$$F = \{e\} \sqcup W(a) \sqcup W(a^{-1}) \sqcup W(b) \sqcup W(b^{-1}), \qquad F = W(a) \sqcup aW(a^{-1}) = W(b) \sqcup bW(b^{-1}).$$

So F is paradoxical*: it is the disjoint union of four pieces, two of which can be translated to give F again, and so can the other two.*

Proof. The first decomposition is the classification of reduced words by their first letter. If $w \notin W(a)$, then $a^{-1}w$ is reduced and begins with a^{-1}, so $w = a(a^{-1}w) \in aW(a^{-1})$. If $u \in W(a^{-1})$, $u = a^{-1}u'$ with u' reduced and not beginning with a, so $au = u' \notin W(a)$. Hence $aW(a^{-1})$ is exactly the complement of $W(a)$; the same for b. □

Remark 28.3.9. *The Banach–Tarski paradox* [BT24]: the closed unit ball of $\mathbb{R}^3$ is the disjoint union of finitely many pieces which can be moved by rigid motions to form two disjoint copies of the ball. The proof transfers Proposition 28.3.8 to geometry: the rotation group SO(3) contains a free group on two generators (for instance the rotations by $\arccos\frac{1}{3}$ about two perpendicular axes); it acts freely on the sphere minus a countable set, and choosing, by the axiom of choice, one point in each orbit transports the paradoxical decomposition of F to the sphere and then, along radii, to the ball, the countable exceptional sets being absorbed by a further trick. The pieces cannot be Lebesgue measurable, since rigid motions preserve measure and $\lambda(B) \neq 2\lambda(B)$; so the theorem says that, as for the Vitali set (Counterexample 28.3.7), no rotation-invariant notion of volume, even finitely additive, extends to all subsets of $\mathbb{R}^3$. On the line, Vitali's argument uses countable additivity in an essential way.

Lemma 28.3.10 (Dynkin)**.** *Let $\mathcal{P}$ be a family of subsets of X closed under finite intersections, and $\mathcal{L} \supseteq \mathcal{P}$ a family containing X, closed under complements and countable disjoint unions. Then $\mathcal{L}$ contains the σ-algebra generated by $\mathcal{P}$. Consequently two measures that agree on $\mathcal{P}$ and are finite on an increasing sequence of sets of $\mathcal{P}$ exhausting X agree on $\sigma(\mathcal{P})$.*

Proof. Let $\mathcal{L}_0$ be the smallest such family containing $\mathcal{P}$. For $A \in \mathcal{P}$, the sets B with $A \cap B \in \mathcal{L}_0$ form such a family (for complements use $A \setminus B = X \setminus ((X \setminus A) \sqcup (A \cap B))$) containing $\mathcal{P}$, hence $\mathcal{L}_0$. Repeating with $A \in \mathcal{L}_0$ shows that $\mathcal{L}_0$ is closed under finite intersections, hence under all countable unions (disjointify), so it is a σ-algebra. For the consequence, if $\mu = \nu$ on $\mathcal{P}$ and $\mu(X_m) = \nu(X_m) < \infty$, the sets B with $\mu(B \cap X_m) = \nu(B \cap X_m)$ form such a family; let $m \to \infty$. □

28.4 The integral

Definition 28.4.1. For a simple function $s = \sum_i a_i \mathbf{1}_{A_i} \geq 0$ with disjoint A_i, $\int s\, d\mu = \sum_i a_i \mu(A_i)$ (independent of the representation, by passing to a common refinement). For measurable $f : X \to [0, \infty]$, $\int f\, d\mu = \sup\{\int s\, d\mu : 0 \leq s \leq f \text{ simple}\}$, and $\int_E f = \int f \mathbf{1}_E$. A measurable $f : X \to \mathbb{C}$ is *integrable* if $\int |f| < \infty$; then $\int f = \int (\operatorname{Re} f)^+ - \int (\operatorname{Re} f)^- + i(\int (\operatorname{Im} f)^+ - \int (\operatorname{Im} f)^-)$, where $g^\pm = \max(\pm g, 0)$.

The idea of the definition. The Riemann integral cuts the *domain* into intervals; the Lebesgue integral cuts the *range*: for $f \geq 0$ and levels $0 = y_0 < y_1 < \cdots$, the simple function $\sum_i y_i \mathbf{1}_{\{y_i \leq f < y_{i+1}\}}$ lies below f, its integral is $\sum_i y_i\, \mu(\{y_i \leq f < y_{i+1}\})$, and refining the levels approximates $\int f$ from below. This only needs the measures of the level sets, which is why it works on any measure space and for very irregular functions.

Example 28.4.2. 1. *Counting measure on* $\mathbb{N}$. For $f : \mathbb{N} \to [0, \infty]$, $\int f\, d\mu = \sum_n f(n)$. If some $f(n) = \infty$ both sides are ∞. Otherwise the functions $s_N = f\mathbf{1}_{\{0,\dots,N\}}$ are simple and satisfy $\int s_N = \sum_{n\le N} f(n)$ and increase to f, so the monotone convergence theorem below gives the claim; a function $f : \mathbb{N} \to \mathbb{C}$ is integrable exactly when $\sum_n |f(n)| < \infty$. So series are integrals, and theorems about integrals specialise to theorems about series.

2. *Dirac measure.* $\int f\, d\delta_x = f(x)$: a simple function $s \le f$ has $\int s\, d\delta_x = s(x) \le f(x)$, and the simple function $f(x)\mathbf{1}_{\{x\}}$ attains it.

3. *The indicator of the rationals.* $\int_{[0,1]} \mathbf{1}_{\mathbb{Q}}\, d\lambda = \lambda(\mathbb{Q} \cap [0, 1]) = 0$, as countable sets have Lebesgue measure 0. The Riemann integral of $\mathbf{1}_{\mathbb{Q}}$ does not exist: every upper sum is 1 and every lower sum is 0.

Theorem 28.4.3 (Monotone convergence)**.** *If* $0 \le f_1 \le f_2 \le \cdots$ *are measurable and* $f = \lim f_n$, *then* $\int f = \lim \int f_n$.

Proof. The integrals increase and are at most $\int f$. Let $0 \le s \le f$ be simple and $0 < c < 1$, and $E_n = \{f_n \ge cs\}$, which increase to X. Then $\int f_n \ge c \int_{E_n} s$, and $A \mapsto \int_A s$ is a measure, so $\int_{E_n} s \to \int s$ (Proposition 28.2.4). Hence $\lim \int f_n \ge c \int s$ for all such c and s. □

Corollary 28.4.4. *1. For measurable* $f, g \ge 0$ *and* $a \ge 0$, $\int (af + g) = a \int f + \int g$, *and* $\int \sum_n f_n = \sum_n \int f_n$.

2. *(Fatou) For measurable* $f_n \ge 0$, $\int \liminf f_n \le \liminf \int f_n$.

3. *The integral is linear on integrable functions and* $|\int f| \le \int |f|$.

4. *For measurable* $f \ge 0$, $\int f = 0$ *if and only if* $f = 0$ *a.e.; and* $\mu(\{f \ge t\}) \le \frac{1}{t} \int f$ *for* $t > 0$ *(Markov's inequality).*

Proof. (1) For simple functions additivity is clear; approximate by increasing simple functions (Proposition 28.2.6(4)) and use monotone convergence. (2) Apply monotone convergence to $g_n = \inf_{k\ge n} f_k$, which satisfy $\int g_n \le \inf_{k\ge n} \int f_k$. (3) Linearity follows from (1) by decomposing into positive and negative parts. For complex f, write $\int f = |\int f| e^{i\theta}$; then $|\int f| = \int \mathrm{Re}(e^{-i\theta} f) \le \int |f|$. (4) $t\mathbf{1}_{\{f\ge t\}} \le f$; and $\{f > 0\} = \bigcup_n \{f \ge 1/n\}$. □

Remark 28.4.5. *Names.* The inequality $\mu(\{f \ge t\}) \le \frac{1}{t} \int f$ is usually called *Markov's inequality*, and some books call it Chebyshev's. *Chebyshev's inequality* proper is the special case applied to $(f - m)^2$: for a probability measure, $f \in L^2$ with mean $m = \int f$ and variance $\sigma^2 = \int (f - m)^2$,

$$\mu(\{|f - m| \ge t\}) = \mu(\{(f - m)^2 \ge t^2\}) \le \frac{\sigma^2}{t^2}.$$

More generally $\mu(\{|f| \ge t\}) \le t^{-p} \int |f|^p$ for $p > 0$. The proof is one line, $t\mathbf{1}_{\{f\ge t\}} \le f$, and it is often all one needs: for instance it shows that convergence in L^p implies convergence in measure (Proposition 28.6.3).

Proposition 28.4.6 (Jensen's inequality)**.** *Let* μ *be a probability measure,* $I \subseteq \mathbb{R}$ *an open interval,* $\varphi : I \to \mathbb{R}$ *convex, and* f *an integrable function with values in* I. *Then* $\int f \in I$, *and*

$$\varphi\Big(\int f\, d\mu\Big) \le \int \varphi \circ f\, d\mu,$$

where the right side is defined in $(-\infty, \infty]$.

Proof. Convex functions. For $s < t < u$ in I, writing $t = \lambda s + (1-\lambda)u$, convexity $\varphi(t) \le \lambda\varphi(s) + (1-\lambda)\varphi(u)$ is equivalent to each of the inequalities between slopes

$$\frac{\varphi(t)-\varphi(s)}{t-s} \le \frac{\varphi(u)-\varphi(s)}{u-s} \le \frac{\varphi(u)-\varphi(t)}{u-t}.$$

So for $c \in I$ the slope $(\varphi(t)-\varphi(c))/(t-c)$ is nondecreasing in $t \neq c$; with $m = \sup_{t<c}(\varphi(t)-\varphi(c))/(t-c) \le \inf_{t>c}(\varphi(t)-\varphi(c))/(t-c)$, a finite number, $\varphi(t) \ge \varphi(c) + m(t-c)$ for all $t \in I$: the graph lies above a line through $(c, \varphi(c))$. The same monotonicity shows that φ has finite one-sided derivatives, so it is continuous, and $\varphi \circ f$ is measurable.

Jensen. Let $c = \int f$. If I is bounded above by b, then $c \le b$, and $c = b$ would force $\int(b-f) = 0$ with $b - f > 0$, which is impossible; similarly at the lower end, so $c \in I$. With m as above, $\varphi(f(x)) \ge \varphi(c) + m(f(x)-c)$; the right side is integrable, so $\int \varphi \circ f$ is defined in $(-\infty, \infty]$, and integrating, using $\mu(X) = 1$, gives $\int \varphi \circ f \ge \varphi(c) + m(c-c) = \varphi(c)$. □

Example 28.4.7.

1. With the convex function $\varphi(t) = |t|^p$ on $\mathbb{R}$, $p \ge 1$, applied to $|f|$: $(\int |f|)^p \le \int |f|^p$ for a probability measure.
2. With $\varphi = \exp$: $\exp(\int f) \le \int e^f$.
3. *Arithmetic and geometric means.* Let μ give mass $\frac{1}{n}$ to each of n points, where f takes the values $a_1, \dots, a_n > 0$, and $\varphi = -\log$. Then $-\log(\frac{1}{n}\sum a_i) \le -\frac{1}{n}\sum \log a_i$, that is, $(a_1 \cdots a_n)^{1/n} \le \frac{1}{n}(a_1 + \cdots + a_n)$.

The hypothesis $\mu(X) = 1$ matters: for Lebesgue measure on $[0,2]$ and $f = 1$, $\varphi(t) = t^2$ gives $\varphi(\int f) = 4 > 2 = \int \varphi(f)$.

Theorem 28.4.8 (Dominated convergence)**.** *Let f_n be measurable with $f_n \to f$ a.e. and $|f_n| \le g$ a.e. for an integrable g. Then f is integrable and $\int |f_n - f| \to 0$; in particular $\int f_n \to \int f$.*

Proof. Modifying on a null set, we may assume convergence and domination everywhere. Then $|f| \le g$, and Fatou's lemma applied to $2g - |f_n - f| \ge 0$ gives $\int 2g \le \int 2g - \limsup \int |f_n - f|$. □

Proposition 28.4.9. *For continuous $f : [a,b] \to \mathbb{C}$, the Lebesgue integral $\int_{[a,b]} f\, d\lambda$ equals the Riemann integral.*

Proof. For a partition P with mesh tending to 0, the step functions $\sum_i \min_{[t_{i-1},t_i]} \operatorname{Re} f \cdot \mathbf{1}_{[t_{i-1},t_i)}$ converge to $\operatorname{Re} f$ uniformly, and their Lebesgue integrals are the lower sums (Theorem 28.3.4). Apply dominated convergence, and treat the imaginary part in the same way. □

Proposition 28.4.10. *Every bounded Riemann integrable function $f : [a,b] \to \mathbb{R}$ (Definition 27.8.1) is Lebesgue measurable and Lebesgue integrable, with the same integral.*

Proof. Choose partitions $P_1, P_2, \dots$, each refining the previous one, with $U(f,P_k) - L(f,P_k) < 1/k$ (Proposition 27.8.2(1)). Let ϕ_k and ψ_k be the step functions equal, on the interior of each interval of P_k, to the infimum and supremum of f there, and to f at the finitely many partition points. Then $\phi_k \le f \le \psi_k$, ϕ_k increases and ψ_k decreases (refinement), and their Lebesgue integrals are $L(f,P_k)$ and $U(f,P_k)$, since points have measure zero. The limits $\phi = \lim \phi_k$ and $\psi = \lim \psi_k$ are measurable, $\phi \le f \le \psi$, and by monotone convergence $\int(\psi - \phi) = \lim(U(f,P_k) - L(f,P_k)) = 0$. So $\psi = \phi$ a.e. (Corollary 28.4.4(4)), hence $f = \phi$ a.e., and f is measurable because Lebesgue measure is complete. Finally $\int f\, d\lambda = \lim \int \phi_k\, d\lambda = \lim L(f,P_k)$, which is the Riemann integral. □

Counterexample 28.4.11. The converse fails. The Dirichlet function $\mathbf{1}_{\mathbb{Q}}$ on $[0,1]$ is Lebesgue integrable with integral 0, since $\mathbb{Q}$ is countable and hence of measure zero. It is not Riemann integrable: every nondegenerate interval contains rational and irrational points, so $L(\mathbf{1}_{\mathbb{Q}}, P) = 0$ and $U(\mathbf{1}_{\mathbb{Q}}, P) = 1$ for every partition P. It is the increasing pointwise limit of the Riemann integrable functions $\mathbf{1}_{\{q_1,\dots,q_n\}}$, each of integral 0, for an enumeration of $\mathbb{Q} \cap [0,1]$: the Riemann integral does not behave well under monotone limits, which is what the Lebesgue integral repairs (Theorem 28.4.3).

Proposition 28.4.12 (Improper integrals)**.** *Let $f : [a,\infty) \to \mathbb{R}$ be continuous, and call $\lim_{b\to\infty} \int_a^b f$, when it exists, the* improper (Riemann) integral $\int_a^\infty f$.

1. *If $f \geq 0$, then $\int_{[a,\infty)} f \, d\lambda = \lim_{b\to\infty} \int_a^b f$ in $[0,\infty]$.*
2. *$f \in L^1([a,\infty))$ if and only if $\int_a^\infty |f| < \infty$, and then the improper integral exists and equals the Lebesgue integral.*
3. *The improper integral can exist without f being Lebesgue integrable: $\int_\pi^\infty \frac{\sin x}{x}\, dx$ converges, but $\int_\pi^\infty \frac{|\sin x|}{x}\, dx = \infty$.*

The same holds for continuous functions on $(a,b]$ with a singularity at a; for instance $\int_0^1 x^{-p}\, dx$ is finite if and only if $p < 1$.

Proof. (1) $f\mathbf{1}_{[a,b]}$ increases to f as $b \to \infty$ (along any sequence $b_n \uparrow \infty$), and $\int_{[a,b]} f \, d\lambda = \int_a^b f$ (Proposition 28.4.9); apply monotone convergence. (2) The first statement is (1) for $|f|$. Then $|f\mathbf{1}_{[a,b]}| \leq |f|$, and dominated convergence gives $\int_a^b f \to \int f \, d\lambda$. (3) On $[k\pi,(k+1)\pi]$ the integral of $|\sin x|/x$ is at least $\frac{2}{(k+1)\pi}$, and $\sum_k \frac{1}{k+1} = \infty$. The integrals $c_k = \int_{k\pi}^{(k+1)\pi} \frac{\sin x}{x}\, dx$ alternate in sign, decrease in absolute value (substitute $x \mapsto x + \pi$) and tend to 0, so $\sum_k c_k$ converges (Lemma 27.5.7); and for b between $k\pi$ and $(k+1)\pi$, $\int_\pi^b$ differs from $\sum_{j<k} c_j$ by at most $|c_k| \to 0$. For x^{-p}, $\int_\varepsilon^1 x^{-p}\, dx = \frac{1-\varepsilon^{1-p}}{1-p}$ for $p \neq 1$ and $-\log\varepsilon$ for $p = 1$. □

So for nonnegative functions the improper integral is the Lebesgue integral, and in general Lebesgue integrability is absolute convergence of the improper integral; the convergent improper integrals of non-integrable functions are the analogue of conditionally convergent series.

Proposition 28.4.13 (Differentiation under the integral sign)**.** *Let (X,μ) be a measure space, $I \subseteq \mathbb{R}$ an open interval, and $f : X \times I \to \mathbb{R}$ such that $f(\cdot,t)$ is integrable for every t, $f(x,\cdot)$ is differentiable for every x, and $|\partial_t f(x,t)| \leq g(x)$ for an integrable g independent of t. Then $F(t) = \int_X f(x,t)\, d\mu(x)$ is differentiable, with $F'(t) = \int_X \partial_t f(x,t)\, d\mu(x)$.*

Proof. For $h_n \to 0$, $(f(x,t+h_n) - f(x,t))/h_n \to \partial_t f(x,t)$, and by the mean value theorem these quotients are bounded by $g(x)$. So $\partial_t f(\cdot,t)$ is measurable, as a limit of measurable functions, and dominated convergence gives $(F(t+h_n) - F(t))/h_n \to \int \partial_t f(x,t)\, d\mu$. □

Example 28.4.14. *Feynman's trick.* Introducing a parameter and differentiating under the integral sign computes integrals that have no elementary antiderivative.

1. $F(t) = \int_0^1 \frac{x^t-1}{\log x}\, dx$ for $t > -1$: here $\partial_t \frac{x^t-1}{\log x} = x^t$, dominated by x^s for $t \geq s > -1$, so $F'(t) = \int_0^1 x^t\, dx = \frac{1}{t+1}$, and $F(0) = 0$ gives $F(t) = \log(1+t)$.

2. $F(t) = \int_{\mathbb{R}} e^{-x^2}\cos(tx)\,dx$. Differentiating, with domination by $|x|e^{-x^2}$, and integrating by parts, $F'(t) = -\int_{\mathbb{R}} xe^{-x^2}\sin(tx)\,dx = -\frac{t}{2}F(t)$; so $F(t) = F(0)e^{-t^2/4} = \sqrt{\pi}\,e^{-t^2/4}$ by Example 28.11.3. This is the Fourier transform of the Gaussian.

3. *The Dirichlet integral* $\int_0^\infty \frac{\sin x}{x}\,dx = \frac{\pi}{2}$ (an improper integral, Proposition 28.4.12(3)). For $t > 0$ let $F(t) = \int_0^\infty e^{-tx}\frac{\sin x}{x}\,dx$, a Lebesgue integral. On $t \geq \delta > 0$ the derivative $-e^{-tx}\sin x$ is dominated by $e^{-\delta x}$, so $F'(t) = -\int_0^\infty e^{-tx}\sin x\,dx = -\operatorname{Im}\int_0^\infty e^{-(t-i)x}\,dx = -\operatorname{Im}\frac{1}{t-i} = -\frac{1}{1+t^2}$. Since $|\sin x/x| \leq 1$, $|F(t)| \leq 1/t \to 0$ as $t \to \infty$; hence $F(t) = \frac{\pi}{2} - \arctan t$, with arctan the inverse of tan: $(-\frac{\pi}{2}, \frac{\pi}{2}) \to \mathbb{R}$. Finally $F(t) \to \int_0^\infty \frac{\sin x}{x}$ as $t \to 0^+$: for a nonincreasing C^1 function $u \geq 0$, integrating by parts, $|\int_R^S u(x)\sin x\,dx| \leq 2u(R)$; with $u(x) = e^{-tx}/x$ this bounds the tails beyond R by $2/R$ for all $t \geq 0$, while $|\int_0^R (e^{-tx}-1)\frac{\sin x}{x}\,dx| \leq \int_0^R tx\,dx = \frac{tR^2}{2}$. Choosing first R large and then t small gives the limit.

28.5 Lebesgue spaces

Definition 28.5.1. For $1 \leq p < \infty$, $L^p(\mu)$ is the space of measurable $f\colon X \to \mathbb{C}$ with $\|f\|_p = (\int |f|^p)^{1/p} < \infty$, modulo equality a.e. $L^\infty(\mu)$ consists of the essentially bounded functions with $\|f\|_\infty = \inf\{c : |f| \leq c \text{ a.e.}\}$, modulo equality a.e. On $L^2(\mu)$ we have the inner product $\langle f, g\rangle = \int f\bar{g}$.

Proposition 28.5.2. *Let $1 \leq p, q \leq \infty$ with $1/p + 1/q = 1$. Then $\int |fg| \leq \|f\|_p\|g\|_q$ (Hölder) and $\|f+g\|_p \leq \|f\|_p + \|g\|_p$ (Minkowski). So $L^p(\mu)$ is a normed space.*

Proof. The cases $p = 1$ or ∞ are clear. For $1 < p < \infty$ and $a, b > 0$, concavity of log ($\log'' < 0$) gives $\log(\frac{a^p}{p} + \frac{b^q}{q}) \geq \log a + \log b$, that is, $ab \leq a^p/p + b^q/q$. If $\|f\|_p = \|g\|_q = 1$, integrating $|fg| \leq |f|^p/p + |g|^q/q$ gives $\int |fg| \leq 1$; the general case follows by scaling. For Minkowski, $|f+g|^p \leq |f||f+g|^{p-1} + |g||f+g|^{p-1}$ and Hölder with $(p-1)q = p$ give $\|f+g\|_p^p \leq (\|f\|_p + \|g\|_p)\|f+g\|_p^{p-1}$; also $|f+g|^p \leq 2^p(|f|^p + |g|^p)$ shows $\|f+g\|_p < \infty$. Functions with $\|f\|_p = 0$ vanish a.e. by Corollary 28.4.4(4). □

Theorem 28.5.3 (Riesz–Fischer). *$L^p(\mu)$ is a Banach space for $1 \leq p \leq \infty$, and every convergent sequence in L^p, $p < \infty$, has a subsequence converging a.e.*

Proof. Let $p < \infty$ and (f_n) Cauchy. Choose $n_1 < n_2 < \cdots$ with $\|f_{n_{k+1}} - f_{n_k}\|_p < 2^{-k}$, and let $g = \sum_k |f_{n_{k+1}} - f_{n_k}|$. By monotone convergence and Minkowski, $\|g\|_p \leq 1$, so $g < \infty$ a.e., and $f = f_{n_1} + \sum_k (f_{n_{k+1}} - f_{n_k})$ converges absolutely a.e. Since $|f - f_{n_k}| \leq \sum_{j\geq k} |f_{n_{j+1}} - f_{n_j}|$, Minkowski gives $\|f - f_{n_k}\|_p \leq 2^{1-k}$, and a Cauchy sequence with a convergent subsequence converges. For $p = \infty$, outside a null set $|f_n - f_m| \leq \|f_n - f_m\|_\infty$ for all n, m, so (f_n) converges uniformly there. □

Proposition 28.5.4. *For $1 \leq p < \infty$, the continuous functions with compact support are dense in $L^p(\mathbb{R}^n, \lambda)$.*

Proof. By Proposition 28.2.6(4) and dominated convergence, simple functions $\sum a_i \mathbf{1}_{E_i}$ with $\lambda(E_i) < \infty$ are dense. Given E with $\lambda(E) < \infty$ and $\varepsilon > 0$, choose compact $K \subseteq E \subseteq U$ open with $\lambda(U \setminus K) < \varepsilon$ (Theorem 28.3.4) and, by Lemma 18.9.5, a continuous $\phi\colon \mathbb{R}^n \to [0,1]$ with compact support in U and $\phi = 1$ on K. Then $\|\mathbf{1}_E - \phi\|_p^p \leq \lambda(U \setminus K) < \varepsilon$. □

Counterexample 28.5.5. The proposition fails for $p = \infty$. Let g be continuous. If $|g| \le c$ almost everywhere on an open set W, then $|g| \le c$ everywhere on W, because $\{x \in W : |g(x)| > c\}$ is open and null, and a nonempty open set has positive measure. Hence $\|g\|_\infty = \sup |g|$, a sequence in $C_c(\mathbb{R}^n)$ that is Cauchy in L^∞ is uniformly Cauchy, and the closure of $C_c(\mathbb{R}^n)$ in L^∞ consists of (classes of) continuous functions vanishing at infinity. For instance, let $H = \{x : x_1 \ge 0\}$ and suppose $\|g - \mathbf{1}_H\|_\infty = c < \frac{1}{2}$ with g continuous. Applying the first remark to $g - 1$ on the interior of H and to g on $\mathbb{R}^n \setminus H$, we get $|g - 1| \le c$ on $\operatorname{int} H$ and $|g| \le c$ on $\mathbb{R}^n \setminus H$; at the origin, which is a limit of points of both sets, continuity gives $g(0) \ge 1 - c > \frac{1}{2}$ and $g(0) \le c < \frac{1}{2}$, a contradiction. So $\mathbf{1}_H$ has distance at least $\frac{1}{2}$ from all continuous functions. In fact $L^\infty([0,1])$ is not separable at all: the functions $\mathbf{1}_{[0,t]}$, $0 < t \le 1$, are uncountably many and pairwise at distance 1.

28.6 Modes of convergence

Definition 28.6.1. Let f_n, f be measurable functions on a measure space (X, μ) with values in $\mathbb{C}$. Then $f_n \to f$ *almost everywhere* if $f_n(x) \to f(x)$ for x outside a null set; *in measure* if $\mu(\{|f_n - f| > \varepsilon\}) \to 0$ for every $\varepsilon > 0$; and *in* L^p if $\|f_n - f\|_p \to 0$.

Theorem 28.6.2 (Egorov)**.** *Let $\mu(X) < \infty$ and $f_n \to f$ almost everywhere. For every $\delta > 0$ there is a measurable E with $\mu(X \setminus E) < \delta$ such that $f_n \to f$ uniformly on E.*

Proof. For $k, n \ge 1$ let $E_{k,n} = \bigcup_{m \ge n} \{|f_m - f| \ge 1/k\}$. For fixed k these sets decrease in n, and their intersection consists of points where $|f_m - f| \ge 1/k$ for infinitely many m, a null set. As $\mu(X) < \infty$, $\mu(E_{k,n}) \to 0$ as $n \to \infty$ (Proposition 28.2.4). Choose n_k with $\mu(E_{k,n_k}) < \delta 2^{-k}$ and let $E = X \setminus \bigcup_k E_{k,n_k}$. Then $\mu(X \setminus E) < \delta$, and on E, $|f_m - f| < 1/k$ for all $m \ge n_k$, for every k. □

Proposition 28.6.3.

1. *If $f_n \to f$ in L^p for some $1 \le p < \infty$, then $f_n \to f$ in measure.*
2. *If $f_n \to f$ in measure, a subsequence converges to f almost everywhere.*
3. *If $\mu(X) < \infty$ and $f_n \to f$ almost everywhere, then $f_n \to f$ in measure.*

Proof. (1) By Markov's inequality (Corollary 28.4.4(4)) applied to $|f_n - f|^p$, $\mu(\{|f_n - f| > \varepsilon\}) \le \varepsilon^{-p} \|f_n - f\|_p^p$. (2) Choose $n_1 < n_2 < \cdots$ with $\mu(A_k) < 2^{-k}$, where $A_k = \{|f_{n_k} - f| > 2^{-k}\}$. The set A of points lying in infinitely many A_k is contained in $\bigcup_{k \ge K} A_k$ for every K, so $\mu(A) \le \sum_{k \ge K} 2^{-k} = 2^{1-K}$ for all K, and $\mu(A) = 0$. For $x \notin A$, $|f_{n_k}(x) - f(x)| \le 2^{-k}$ for large k. (3) Given $\varepsilon, \delta > 0$, Egorov's theorem gives E with $\mu(X \setminus E) < \delta$ and $|f_n - f| < \varepsilon$ on E for large n, so $\mu(\{|f_n - f| > \varepsilon\}) < \delta$ for large n. □

Counterexample 28.6.4. No other implications hold in general. Take $X = [0,1]$ or $\mathbb{R}$ with Lebesgue measure.

1. $f_n = n\mathbf{1}_{(0,1/n)}$ on $[0,1]$ converges to 0 everywhere, but $\int f_n = 1$: almost everywhere convergence and convergence in measure do not imply L^1 convergence, even on a finite measure space.
2. $f_n = \mathbf{1}_{[n,n+1]}$ on $\mathbb{R}$ converges to 0 everywhere but not in measure, as $\lambda(\{f_n > \frac{1}{2}\}) = 1$: part (3) of Proposition 28.6.3 and Egorov's theorem need $\mu(X) < \infty$.
3. (The typewriter sequence.) For $n = 2^k + j$ with $0 \le j < 2^k$ let $f_n = \mathbf{1}_{[j2^{-k},(j+1)2^{-k}]}$ on $[0,1]$. Then $\|f_n\|_1 = 2^{-k} \to 0$, so $f_n \to 0$ in L^1 and in measure; but every $x \in [0,1]$ lies in one of the intervals for each k and outside most of them, so $f_n(x) = 1$ and $f_n(x) = 0$ both happen infinitely often, and $(f_n(x))$ converges for no x. The subsequence in part (2) of Proposition 28.6.3 is necessary.

28.7 Independence and the Borel–Cantelli lemmas

Measure theory is also the language of probability. A *probability space* is a measure space $(\Omega, \mathcal{F}, P)$ with $P(\Omega) = 1$; its measurable sets are called *events*, measurable functions are *random variables*, and "almost everywhere" becomes *almost surely*. A typical question asks whether infinitely many of a sequence of events happen. For events $A_1, A_2, \dots$ the event "A_k happens for infinitely many k" is

$$\limsup_k A_k = \bigcap_{n \ge 1} \bigcup_{k \ge n} A_k = \{\omega : \omega \in A_k \text{ for infinitely many } k\},$$

and its complement is $\liminf_k A_k^c = \bigcup_n \bigcap_{k \ge n} A_k^c$, "from some index on, no A_k happens". The two Borel–Cantelli lemmas decide, in many cases, whether $\limsup_k A_k$ has probability 0 or 1. The first needs nothing; the second needs independence, which we now define.

Definition 28.7.1. Events $A_1, A_2, \dots$ (finitely or countably many) in a probability space are *independent* if

$$P(A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m}) = P(A_{k_1})P(A_{k_2}) \cdots P(A_{k_m})$$

for all m and all distinct indices $k_1, \dots, k_m$.

The condition must be imposed on all subfamilies, not only on pairs.

Example 28.7.2. Toss two fair coins: $\Omega = \{HH, HT, TH, TT\}$, each point with probability $\frac{1}{4}$. Let A = "the first coin shows heads", B = "the second coin shows heads", C = "the two coins agree". Each event has probability $\frac{1}{2}$, and each intersection of two of them has probability $\frac{1}{4}$; so they are pairwise independent. But $A \cap B \cap C = \{HH\}$ has probability $\frac{1}{4} \neq \frac{1}{8}$: if two of the events happen, so does the third.

Lemma 28.7.3. *If $A_1, A_2, \dots$ are independent, so are the events obtained by replacing any of the A_k by their complements.*

Proof. It suffices to replace one event, say A_1, by A_1^c; replacing several is done one at a time. Let $k_2, \dots, k_m$ be distinct indices different from 1 and $B = A_{k_2} \cap \cdots \cap A_{k_m}$ (with $B = \Omega$ if $m = 1$). Then $P(A_1^c \cap B) = P(B) - P(A_1 \cap B) = P(B) - P(A_1)P(B) = P(A_1^c)P(B)$, and $P(B)$ is the product of the $P(A_{k_j})$. Intersections not involving A_1^c are unchanged. □

The basic example of independence lives on $[0, 1)$ with Lebesgue measure: the binary digits of a number chosen at random behave like independent tosses of a fair coin. For $x \in [0, 1)$ and $k \ge 1$ let

$$d_k(x) = \lfloor 2^k x \rfloor - 2\lfloor 2^{k-1} x \rfloor \in \{0, 1\},$$

the k-th digit of the binary expansion $x = \sum_k d_k(x) 2^{-k}$ that does not end with infinitely many 1s. For $K \ge 1$ the integer $\lfloor 2^K x \rfloor$ has binary digits $d_1(x), \dots, d_K(x)$, so $d_1(x) = \delta_1, \dots, d_K(x) = \delta_K$ holds exactly on the interval $[N2^{-K}, (N+1)2^{-K})$ with $N = \sum_{k \le K} \delta_k 2^{K-k}$, of length 2^{-K}. Call a set $E \subseteq [0, 1)$ *determined by* a finite set S of positions if whether $x \in E$ depends only on the digits $d_k(x)$, $k \in S$.

Lemma 28.7.4. 1. *For a finite set S of positions and prescribed digits $\delta_k \in \{0, 1\}$, $k \in S$, the set $\{x : d_k(x) = \delta_k \text{ for } k \in S\}$ has measure $2^{-|S|}$.*

2. *If $E_1, \dots, E_m$ are determined by pairwise disjoint finite sets of positions $S_1, \dots, S_m$, then $\lambda(E_1 \cap \cdots \cap E_m) = \lambda(E_1) \cdots \lambda(E_m)$. Consequently, events $E_1, E_2, \dots$ determined by pairwise disjoint finite sets of positions are independent; in particular the events $\{d_k = 1\}$, $k \ge 1$, are independent of probability $\frac{1}{2}$.*

3. *If $g_i = G_i\big((d_k)_{k\in S_i}\big)$ for functions G_i of finitely many digits and pairwise disjoint $S_1, \dots, S_m$, then $\int_0^1 g_1 \cdots g_m \, d\lambda = \prod_i \int_0^1 g_i \, d\lambda$.*

Proof. (1) Let $K = \max S$ (the case $S = \emptyset$ is trivial). The set is the disjoint union, over the $2^{K-|S|}$ choices of the digits at the positions in $\{1, \dots, K\} \setminus S$, of intervals of length 2^{-K}, so its measure is $2^{K-|S|}2^{-K}$.

(2) A set determined by S_i is a disjoint union of n_i sets as in (1), one for each admissible pattern of digits on S_i, so $\lambda(E_i) = n_i 2^{-|S_i|}$. With $S = S_1 \cup \cdots \cup S_m$, the intersection $E_1 \cap \cdots \cap E_m$ is the disjoint union of the sets of (1) for the patterns on S whose restriction to each S_i is admissible for E_i; there are $n_1 \cdots n_m$ of them, so its measure is $n_1 \cdots n_m 2^{-|S|} = \prod_i n_i 2^{-|S_i|}$. A subfamily of the E_k is again determined by disjoint sets of positions, which gives independence.

(3) Each g_i is a finite linear combination of indicator functions of sets determined by S_i; expand the product and apply (2) to each term. □

Theorem 28.7.5 (Borel–Cantelli lemmas)**.** *Let $A_1, A_2, \dots$ be events in a probability space.*

1. *If $\sum_k P(A_k) < \infty$, then $P(\limsup_k A_k) = 0$: almost surely only finitely many A_k happen.*
2. *If the A_k are independent and $\sum_k P(A_k) = \infty$, then $P(\limsup_k A_k) = 1$: almost surely infinitely many A_k happen.*

Proof. (1) For every n, $\limsup_k A_k \subseteq \bigcup_{k\ge n} A_k$, so $P(\limsup_k A_k) \le \sum_{k\ge n} P(A_k)$, the tail of a convergent series, which tends to 0 as $n \to \infty$.

(2) We show that the complement $\bigcup_n \bigcap_{k\ge n} A_k^c$ is null; it suffices to show $P(\bigcap_{k\ge n} A_k^c) = 0$ for each n. For $N \ge n$, the events A_k^c are independent (Lemma 28.7.3), and $1 - t \le e^{-t}$ for real t (the exponential lies above its tangent line at 0), so

$$P\Big(\bigcap_{k=n}^{N} A_k^c\Big) = \prod_{k=n}^{N} \big(1 - P(A_k)\big) \le \exp\Big(-\sum_{k=n}^{N} P(A_k)\Big) \longrightarrow 0 \qquad (N \to \infty).$$

These sets decrease in N to $\bigcap_{k\ge n} A_k^c$, so by continuity of measures (Proposition 28.2.4) its probability is 0. □

For independent events $\limsup_k A_k$ therefore has probability 0 or 1, never anything in between: a first instance of a *zero-one law*. The first lemma was already used, without the name, in the proof of Proposition 28.6.3(2).

Counterexample 28.7.6. Independence cannot be dropped in (2). On $[0,1)$ let $A_k = [0, 1/k)$. Then $\sum_k \lambda(A_k) = \sum_k 1/k = \infty$, but the sets decrease, so $\limsup_k A_k = \bigcap_k A_k = \{0\}$, a null set. The events are far from independent: $\lambda(A_j \cap A_k) = 1/\max(j,k)$, not $1/(jk)$. Even more simply, $A_k = A$ for all k with $\lambda(A) = \frac{1}{2}$ gives $\limsup_k A_k = A$, of probability $\frac{1}{2}$.

Example 28.7.7. *Every pattern appears infinitely often.* Fix a block $\beta = (\beta_1, \dots, \beta_m)$ of binary digits. For $j \ge 0$ let B_j be the event that the digits at positions $jm+1, \dots, jm+m$ form the block β. These events are determined by the disjoint sets of positions $\{jm+1, \dots, jm+m\}$, so they are independent, each of probability 2^{-m} (Lemma 28.7.4). Since $\sum_j 2^{-m} = \infty$, almost every $x \in [0,1)$ lies in infinitely many B_j. There are countably many blocks, so for almost every x every finite block of digits occurs infinitely often in the binary expansion of x. (Encoding letters by blocks of digits, this is the "infinite monkey theorem": a random infinite text contains every book infinitely often.)

The probability of a long block is small, and this limits how long the runs of 1s in a random expansion can be. Let $R_n(x)$ be the length of the run of 1s starting at position n: the largest $r \ge 0$ with $d_n(x) = \cdots = d_{n+r-1}(x) = 1$, which is finite because the expansion does not end with infinitely many 1s.

Proposition 28.7.8 (Long runs). *For almost every $x \in [0,1)$, $\limsup_{n\to\infty} \dfrac{R_n(x)}{\log_2 n} = 1$.*

Proof. Upper bound. For $r > 0$, $R_n \geq r$ means that the $\lceil r \rceil$ digits from position n on are 1, so $\lambda(R_n \geq r) = 2^{-\lceil r \rceil} \leq 2^{-r}$ by Lemma 28.7.4(1). For $\varepsilon > 0$ and $r = (1+\varepsilon)\log_2 n$ this is at most $n^{-1-\varepsilon}$, which is summable. By Theorem 28.7.5(1), for almost every x we have $R_n(x) < (1+\varepsilon)\log_2 n$ for all large n, so the lim sup is at most $1+\varepsilon$. Let $\varepsilon = 1/m$, $m = 1, 2, \ldots$, and discard countably many null sets.

Lower bound. We need independent events, so we use disjoint windows. For $j \geq 2$ let $L_j = \lfloor \log_2 j \rfloor \geq 1$, $s_2 = 1$ and $s_{j+1} = s_j + L_j$, so that the windows $W_j = \{s_j, \ldots, s_j + L_j - 1\}$ are disjoint. Let E_j be the event that all digits in W_j are 1; then $E_j \subseteq \{R_{s_j} \geq L_j\}$, and $\lambda(E_j) = 2^{-L_j} \geq 1/j$. The E_j are independent (Lemma 28.7.4(2)) and $\sum_j 1/j = \infty$, so by Theorem 28.7.5(2) almost every x lies in infinitely many E_j. Now $s_j = 1 + \sum_{2 \leq i < j} L_i \leq j \log_2 j$, so $\log_2 s_j \leq \log_2 j + \log_2 \log_2 j$, while $L_j \geq \log_2 j - 1$. Hence for such x,

$$\frac{R_{s_j}(x)}{\log_2 s_j} \geq \frac{\log_2 j - 1}{\log_2 j + \log_2 \log_2 j}$$

for infinitely many j, and the right side tends to 1. So the lim sup is at least 1. □

So among the first n tosses of a fair coin one should expect a run of heads of length about $\log_2 n$, and no essentially longer one: about 10 in a thousand tosses, 20 in a million. This is a form of the *Erdős–Rényi law of long runs*; people asked to write down "random" sequences typically avoid such long runs, which is a simple way to detect fake randomness.

The most famous application of the first lemma is Borel's theorem that almost every number is *normal*: its digits appear with the frequencies one expects. We prove the simplest case.

Theorem 28.7.9 (Borel's normal number theorem). *For almost every $x \in [0,1)$,*

$$\lim_{n\to\infty} \frac{d_1(x) + d_2(x) + \cdots + d_n(x)}{n} = \frac{1}{2}.$$

Proof. Let $\rho_k = 2d_k - 1 \in \{-1, 1\}$ and $S_n = \rho_1 + \cdots + \rho_n$; the claim is $S_n/n \to 0$ almost everywhere.

Step 1: the fourth moment. Expanding, $\int_0^1 S_n^4 = \sum_{i,j,k,l \leq n} \int_0^1 \rho_i \rho_j \rho_k \rho_l$. Since $\rho^2 = 1$, a product $\rho_i\rho_j\rho_k\rho_l$ in which some index occurs an odd number of times reduces to a product ρ_a or $\rho_a\rho_b$ ($a \neq b$), whose integral is $\int \rho_a \cdot \int \rho_b = 0$ by Lemma 28.7.4(3), because $\int_0^1 \rho_a = \frac{1}{2} - \frac{1}{2} = 0$. The remaining terms equal 1: either all four indices are equal (n terms), or they take two different values, each twice ($3n(n-1)$ terms: choose which of the three pairings of the four places carry equal indices, then the two values in order). So $\int_0^1 S_n^4 = n + 3n(n-1) \leq 3n^2$.

Step 2: Borel–Cantelli. Let $\varepsilon > 0$. By Markov's inequality (Corollary 28.4.4(4)) applied to S_n^4,

$$\lambda\big(|S_n| \geq \varepsilon n\big) \leq \frac{1}{\varepsilon^4 n^4} \int_0^1 S_n^4 \leq \frac{3}{\varepsilon^4 n^2},$$

which is summable in n. By Theorem 28.7.5(1), for almost every x we have $|S_n(x)| < \varepsilon n$ for all large n. Taking $\varepsilon = 1/m$ for all m and discarding countably many null sets, $S_n/n \to 0$ almost everywhere. Since $d_k = (1+\rho_k)/2$, the average of the first n digits is $\frac{1}{2} + S_n/(2n) \to \frac{1}{2}$. □

Remark 28.7.10. The same argument, applied to the blocks of Example 28.7.7 and to expansions in any base $b \geq 2$, shows that almost every real number is *normal in every base*: in base b, each block of m digits occurs with limiting frequency b^{-m} [Bor09]. The theorem is the strong

law of large numbers for fair coin tosses. It is a striking example of an existence proof by measure: almost all numbers are normal, yet it is not known whether $\sqrt{2}$, e or π is normal in any base. Explicit normal numbers can be constructed, such as Champernowne's number $0.123456789101112\ldots$, obtained by writing the positive integers one after another, which is normal in base 10 [Cha33].

Example 28.7.11. *Almost no number is very well approximable.* By Dirichlet's approximation theorem (Exercise 28.23.24), every irrational x has infinitely many approximations p/q with $|x - p/q| < 1/q^2$. The exponent 2 cannot be improved for almost all x. Fix $\varepsilon > 0$ and for $q \geq 1$ let A_q be the set of $x \in [0,1]$ for which some integer p satisfies $|x - p/q| < q^{-2-\varepsilon}$. Only $p = -1, 0, \ldots, q+1$ can occur, so A_q is covered by $q+3$ intervals of length $2q^{-2-\varepsilon}$, and $\lambda(A_q) \leq 2(q+3)q^{-2-\varepsilon} \leq 8q^{-1-\varepsilon}$, which is summable. By Theorem 28.7.5(1), almost every x lies in only finitely many A_q, and hence has only finitely many approximations with $|x - p/q| < q^{-2-\varepsilon}$. In particular the *Liouville numbers*, the irrational x that for every n have an approximation p/q with $q \geq 2$ and $|x - p/q| < q^{-n}$, form a null set. An example is $\sum_{k\geq 1} 10^{-k!}$: cutting the series after the term $k = m$ gives p/q with $q = 10^{m!}$ and error less than $2 \cdot 10^{-(m+1)!} = 2q^{-(m+1)}$.

28.8 Littlewood's principles and Lusin's theorem

Littlewood summarised the theory of Lebesgue measure on $\mathbb{R}^n$ in three principles: every measurable set of finite measure is nearly a finite union of boxes; every measurable function is nearly continuous; every convergent sequence of measurable functions is nearly uniformly convergent. The third is Egorov's theorem (Theorem 28.6.2); this section makes the first two precise. Throughout, λ is Lebesgue measure on $\mathbb{R}^n$ and $E \mathbin{\triangle} A = (E \setminus A) \cup (A \setminus E)$ is the symmetric difference.

Lemma 28.8.1. *Every open set $W \subseteq \mathbb{R}^n$ is a countable union of closed* dyadic cubes $\prod_i [k_i 2^{-j}, (k_i+1)2^{-j}]$ *($j \in \mathbb{N}$, $k_i \in \mathbb{Z}$) with pairwise disjoint interiors, and $\lambda(W)$ is the sum of their volumes.*

Proof. Two dyadic cubes of side at most 1 are either nested or have disjoint interiors, and a dyadic cube of side at most 1 is contained in only finitely many dyadic cubes of side at most 1. Every $x \in W$ lies in a dyadic cube of side at most 1 contained in W, since W contains a ball around x. Let (Q_k) be the dyadic cubes of side at most 1 contained in W that are maximal for inclusion among these; every dyadic cube of side at most 1 in W lies in one of them, so they cover W, and distinct maximal cubes have disjoint interiors. There are countably many dyadic cubes. The boundary of a cube is a finite union of boxes of volume 0, a null set (Theorem 28.3.4), so the interiors, which are disjoint, have the same measures as the cubes, and $\lambda(W) = \sum_k \lambda(Q_k)$ by countable additivity. □

Proposition 28.8.2 (First principle)**.** *Let $E \subseteq \mathbb{R}^n$ be Lebesgue measurable with $\lambda(E) < \infty$, and $\varepsilon > 0$. There is a finite union A of boxes with $\lambda(E \mathbin{\triangle} A) < \varepsilon$.*

Proof. By Theorem 28.3.4 there is an open $W \supseteq E$ with $\lambda(W \setminus E) < \varepsilon/2$. Write $W = \bigcup_k Q_k$ as in Lemma 28.8.1. Since $\sum_k \lambda(Q_k) = \lambda(W) < \infty$, there is N with $\sum_{k>N} \lambda(Q_k) < \varepsilon/2$. Let $A = Q_1 \cup \cdots \cup Q_N$. Then $\lambda(A \setminus E) \leq \lambda(W \setminus E) < \varepsilon/2$ and $\lambda(E \setminus A) \leq \lambda(W \setminus A) \leq \sum_{k>N} \lambda(Q_k) < \varepsilon/2$. □

Theorem 28.8.3 (Lusin)**.** *Let $E \subseteq \mathbb{R}^n$ be Lebesgue measurable with $\lambda(E) < \infty$, let $f : E \to \mathbb{C}$ be measurable, and $\varepsilon > 0$. There is a compact set $K \subseteq E$ with $\lambda(E \setminus K) < \varepsilon$ such that the restriction $f|_K$ is continuous. Moreover there is $g \in C_c(\mathbb{R}^n)$ with $g = f$ on K, and if $|f| \leq c$ on E we can take $|g| \leq c$.*

Proof. Step 1: indicator functions. Let $f = \mathbf{1}_A$ with $A \subseteq E$ measurable. By inner regularity (Theorem 28.3.4) there are compact sets $K_1 \subseteq A$ and $K_2 \subseteq E \setminus A$ with $\lambda(A \setminus K_1) < \varepsilon/2$ and $\lambda((E \setminus A) \setminus K_2) < \varepsilon/2$. Then $K = K_1 \cup K_2$ is compact with $\lambda(E \setminus K) < \varepsilon$. As K_1 and K_2 are disjoint and closed, each is open in K, and $f|_K$ is constant on each, hence continuous.

Step 2: simple functions. If $f = \sum_{i=1}^{m} a_i \mathbf{1}_{A_i}$, apply Step 1 to each A_i with ε/m and intersect the compact sets.

Step 3: real functions. By Proposition 28.2.6(4), applied to f^+ and f^-, there are simple functions s_k with $s_k \to f$ pointwise on E. By Step 2 there are compact $K_k \subseteq E$ with $\lambda(E \setminus K_k) < \varepsilon 2^{-k-2}$ and $s_k|_{K_k}$ continuous. By Egorov's theorem (Theorem 28.6.2, on the finite measure space E) there is a measurable $F \subseteq E$ with $\lambda(E \setminus F) < \varepsilon/4$ on which $s_k \to f$ uniformly, and by inner regularity a compact $K_0 \subseteq F$ with $\lambda(F \setminus K_0) < \varepsilon/4$. The compact set $K = K_0 \cap \bigcap_k K_k$ satisfies $\lambda(E \setminus K) < \varepsilon/4 + \varepsilon/4 + \sum_k \varepsilon 2^{-k-2} \le \varepsilon$, and on it the continuous functions $s_k|_K$ converge uniformly to $f|_K$, which is therefore continuous (Proposition 18.3.10). For complex f, treat the real and imaginary parts with $\varepsilon/2$ each and intersect.

Extension. The space $\mathbb{R}^n$ is metric, hence normal (Proposition 18.8.3), and K is closed, so by the Tietze extension theorem (Theorem 18.8.5) the real and imaginary parts of $f|_K$ extend to continuous functions on $\mathbb{R}^n$; let h be the resulting extension of $f|_K$. If $|f| \le c$, replace h by $r \circ h$, where $r(z) = z$ for $|z| \le c$ and $r(z) = cz/|z|$ otherwise is a continuous retraction of $\mathbb{C}$ onto the closed disc of radius c. Finally choose $\phi \in C_c(\mathbb{R}^n)$ with values in $[0,1]$ and $\phi = 1$ on K (Lemma 18.9.5), and let $g = \phi h$. □

Example 28.8.4. Lusin's theorem says that the *restriction* of f to K is continuous, not that f is continuous at the points of K. The Dirichlet function $\mathbf{1}_{\mathbb{Q}}$ on $[0,1]$ is discontinuous at every point. Enumerate $\mathbb{Q} \cap [0,1] = \{q_1, q_2, \ldots\}$ and let U be the union of the intervals $(q_k - \varepsilon 2^{-k-2}, q_k + \varepsilon 2^{-k-2})$. Then $\lambda(U) \le \varepsilon/2$, the set $K = [0,1] \setminus U$ is compact with $\lambda([0,1] \setminus K) < \varepsilon$, and $\mathbf{1}_{\mathbb{Q}}$ vanishes on K, so its restriction to K is continuous.

Corollary 28.8.5. *Every measurable function $f : \mathbb{R}^n \to \mathbb{C}$ is the almost everywhere limit of a sequence of continuous functions.*

Proof. For $k \ge 1$ apply Theorem 28.8.3 to the restriction of f to the ball $B(0,k)$ with $\varepsilon = 2^{-k}$, to get $g_k \in C_c(\mathbb{R}^n)$ equal to f on $B(0,k)$ outside a set N_k of measure less than 2^{-k}. By monotone convergence, $\int \sum_k \mathbf{1}_{N_k} = \sum_k \lambda(N_k) < \infty$, so $\sum_k \mathbf{1}_{N_k} < \infty$ almost everywhere: almost every x lies in only finitely many N_k. For such x and all large $k > \|x\|$, $g_k(x) = f(x)$. □

28.9 Differentiation of integrals

For a continuous function f on $\mathbb{R}$, the fundamental theorem of calculus says that $\frac{1}{2r}\int_{x-r}^{x+r} f \to f(x)$. We show that the averages of an integrable function over small balls converge to the function almost everywhere. Let $B(x,r)$ be the open Euclidean ball. The map $y \mapsto x + ry$ multiplies the volume of boxes by r^n, hence Lebesgue measure by r^n, so $\lambda(B(x,r)) = r^n \lambda(B(0,1))$. A measurable function is *locally integrable*, $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$, if $\int_K |f| < \infty$ for every compact K.

Lemma 28.9.1 (Vitali covering lemma)**.** *Every finite family of open balls $B_1, \ldots, B_m$ in $\mathbb{R}^n$ has a pairwise disjoint subfamily $B_{i_1}, \ldots, B_{i_k}$ with $\bigcup_i B_i \subseteq \bigcup_j 3B_{i_j}$, where $3B(x,r) = B(x,3r)$. Consequently $\lambda(\bigcup_i B_i) \le 3^n \sum_j \lambda(B_{i_j})$.*

Proof. Choose a ball of largest radius, discard all the balls that meet it, choose a ball of largest radius among the remaining ones, and so on. The chosen balls are pairwise disjoint. A discarded ball $B = B(c,r)$ meets a chosen ball $B' = B(c',r')$ with $r' \ge r$, namely the one chosen at the step where B was discarded. If $z \in B \cap B'$ and $y \in B$, then

$\|y - c'\| \le \|y - c\| + \|c - z\| + \|z - c'\| < r + r + r' \le 3r'$, so $B \subseteq 3B'$. The inequality follows from $\lambda(3B') = 3^n\lambda(B')$ and subadditivity. □

Definition 28.9.2. For $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$, $x \in \mathbb{R}^n$ and $r > 0$, the *average* of f over $B(x,r)$ is $A_r f(x) = \frac{1}{\lambda(B(x,r))}\int_{B(x,r)} f\,d\lambda$, and the *Hardy–Littlewood maximal function* is $Mf(x) = \sup_{r>0} A_r|f|(x) \in [0,\infty]$.

Theorem 28.9.3 (Hardy–Littlewood maximal inequality)**.** *Let $f \in L^1(\mathbb{R}^n)$ and $t > 0$. The set $\{Mf > t\}$ is open, and $\lambda(\{Mf > t\}) \le \frac{3^n}{t}\|f\|_1$.*

Proof. If $A_r|f|(x) > t$, choose $s > r$ with $(r/s)^n A_r|f|(x) > t$. For $\|x' - x\| < s - r$ we have $B(x',s) \supseteq B(x,r)$, so $A_s|f|(x') \ge (r/s)^n A_r|f|(x) > t$; hence $\{Mf > t\}$ is open. Let $K \subseteq \{Mf > t\}$ be compact. Every $x \in K$ is the centre of a ball B_x with $\int_{B_x}|f| > t\lambda(B_x)$, and finitely many of these balls cover K. By Lemma 28.9.1 they contain disjoint balls $B_1, \dots, B_k$ with

$$\lambda(K) \le 3^n \sum_j \lambda(B_j) < \frac{3^n}{t}\sum_j \int_{B_j}|f| \le \frac{3^n}{t}\|f\|_1.$$

By inner regularity (Theorem 28.3.4), the same bound holds for $\{Mf > t\}$. □

Theorem 28.9.4 (Lebesgue differentiation theorem)**.** *Let $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$. For almost every $x \in \mathbb{R}^n$,*

$$\lim_{r\to 0}\frac{1}{\lambda(B(x,r))}\int_{B(x,r)}|f(y) - f(x)|\,d\lambda(y) = 0,$$

and in particular $A_r f(x) \to f(x)$ as $r \to 0$.

Proof. For $x \in B(0,R)$ and $r < 1$ the quantity only involves f on $B(0,R+1)$, so, replacing f by $f\mathbf{1}_{B(0,R+1)}$ and letting R run through $\mathbb{N}$, we may assume $f \in L^1(\mathbb{R}^n)$. Let $\Omega_f(x) = \limsup_{r\to 0} A_r|f - f(x)|(x)$. Fix $t > 0$ and $\varepsilon > 0$, and choose $g \in C_c(\mathbb{R}^n)$ with $\|f - g\|_1 < \varepsilon$ (Proposition 28.5.4). For the continuous g, $A_r|g - g(x)|(x) \le \sup_{B(x,r)}|g - g(x)| \to 0$, so $\Omega_g = 0$. With $h = f - g$ we have $|f(y) - f(x)| \le |h(y)| + |h(x)| + |g(y) - g(x)|$, hence $\Omega_f(x) \le Mh(x) + |h(x)|$, and

$$\{\Omega_f > 2t\} \subseteq \{Mh > t\} \cup \{|h| > t\}.$$

By Theorem 28.9.3 and Markov's inequality (Corollary 28.4.4(4)), the right side has measure at most $3^n\varepsilon/t + \varepsilon/t$. As ε is arbitrary, $\{\Omega_f > 2t\}$ has outer measure 0, so it is a null set (Lebesgue measure is complete), and so is the union of these sets for $t = 1/k$, $k \ge 1$. Finally $|A_r f(x) - f(x)| \le A_r|f - f(x)|(x)$. □

The points where the conclusion holds are the *Lebesgue points* of f; changing f on a null set does not change the averages, so almost every point is a Lebesgue point of every representative.

Corollary 28.9.5 (Lebesgue density theorem)**.** *Let $A \subseteq \mathbb{R}^n$ be Lebesgue measurable. Then $\lambda(A \cap B(x,r))/\lambda(B(x,r)) \to 1$ as $r \to 0$ for almost every $x \in A$, and $\to 0$ for almost every $x \notin A$.*

Proof. Apply Theorem 28.9.4 to the bounded, hence locally integrable, function $\mathbf{1}_A$, whose average over $B(x,r)$ is the ratio in question. □

Corollary 28.9.6 (Fundamental theorem of calculus for Lebesgue integrals)**.** *Let $f \in L^1([a,b])$ and $F(x) = \int_{[a,x]} f\,d\lambda$. Then F is continuous, and at almost every $x \in (a,b)$ it is differentiable with $F'(x) = f(x)$.*

Proof. Extend f by 0 to $\mathbb{R}$. For $y \to x$, $|F(y) - F(x)| \le \int \mathbf{1}_{[x,y]}|f| \to 0$ by dominated convergence, where $[x, y]$ means the interval between x and y. For $h \neq 0$ let I_h be the closed interval between x and $x + h$, of length $|h|$. Then $F(x + h) - F(x) = \pm \int_{I_h} f$, with the sign of h, so in both cases $\frac{F(x+h)-F(x)}{h} - f(x) = \frac{1}{|h|} \int_{I_h} (f - f(x))$. As $I_h \subseteq \overline{B}(x, |h|)$, an interval of length $2|h|$ whose endpoints are null,

$$\left|\frac{F(x + h) - F(x)}{h} - f(x)\right| \le \frac{1}{|h|} \int_{B(x,|h|)} |f - f(x)| = 2A_{|h|}|f - f(x)|(x),$$

which tends to 0 at every Lebesgue point of f. □

Counterexample 28.9.7. *The Cantor function.* A continuous nondecreasing function can have derivative 0 almost everywhere without being constant, so the formula $F(b) - F(a) = \int_a^b F'$ fails for such functions. Let $C \subseteq [0, 1]$ be the Cantor set, the set of numbers $\sum_{k\ge1} a_k 3^{-k}$ with all $a_k \in \{0, 2\}$; these expansions are unique, and C is compact of measure zero, being covered, for each k, by 2^k intervals of length 3^{-k} (Exercise 28.23.1). Define $c : C \to [0, 1]$ by $c(\sum_k a_k 3^{-k}) = \sum_k (a_k/2)2^{-k}$.

1. c is nondecreasing and surjective. If $x < y$ in C, their digits first differ at some k with $a_k = 0$ and $b_k = 2$ (a difference $2 \cdot 3^{-k}$ in position k cannot be compensated by the later digits, which contribute at most $\sum_{j>k} 2 \cdot 3^{-j} = 3^{-k}$); then $c(y) - c(x) \ge 2^{-k} - \sum_{j>k} 2^{-j} = 0$. Every $t \in [0, 1]$ has a binary expansion $\sum_k b_k 2^{-k}$, and $t = c(\sum_k 2b_k 3^{-k})$.

2. Let $F(x) = \sup\{c(y) : y \in C, y \le x\}$ for $x \in [0, 1]$. Then F is nondecreasing, $F = c$ on C, and $F([0, 1]) = [0, 1]$. A nondecreasing function whose image is an interval has no jumps, so F is continuous.

3. The complement $[0, 1] \setminus C$ is a countable union of open intervals (α, β) with $\alpha \in C$, removed in the construction; on each of them $F = c(\alpha)$ is constant, as C has no point in (α, β). So $F' = 0$ on $[0, 1] \setminus C$, that is, almost everywhere, while $F(1) - F(0) = 1$.

So F is not the integral of its derivative. The functions that are integrals of their derivatives are exactly the *absolutely continuous* ones [Rud87, Chapter 7]. Note also that the continuous map F sends the null set C onto $[0, 1]$.

Counterexample 28.9.8. *A Lebesgue measurable set that is not a Borel set.* First, every $A \subseteq \mathbb{R}$ with $\lambda^*(A) > 0$ contains a non-measurable subset. Let V be as in Counterexample 28.3.7. If S is a measurable subset of a translate $V + q$, $q \in \mathbb{Q}$, then the sets $S - q + q'$, $q' \in \mathbb{Q} \cap [-1, 1]$, are pairwise disjoint (they lie in the disjoint translates $V + q'$), contained in $[-1, 2]$, and all of measure $\lambda(S)$; so $\lambda(S) = 0$. The sets $A \cap (V + q)$, $q \in \mathbb{Q}$, cover A, since every real number differs from an element of V by a rational; if they were all measurable, A would be a countable union of null sets.

Now let F be the Cantor function and $h(x) = x + F(x)$ on $[0, 1]$. It is continuous and strictly increasing from $[0, 1]$ onto $[0, 2]$, hence a homeomorphism. It maps each interval (α, β) of $[0, 1] \setminus C$ onto an interval of the same length, since F is constant there; these images are disjoint, so $\lambda(h([0, 1] \setminus C)) = 1$ and $\lambda(h(C)) = 1$. Choose a non-measurable $N \subseteq h(C)$. Then $h^{-1}(N) \subseteq C$ is a subset of a null set, hence Lebesgue measurable. It is not a Borel set: otherwise N, its preimage under the continuous map h^{-1}, would be Borel, hence measurable. In particular, a composite of a Lebesgue measurable function with a continuous one need not be Lebesgue measurable: $\mathbf{1}_{h^{-1}(N)} \circ h^{-1} = \mathbf{1}_N$.

28.10 Product measures and Fubini's theorem

Definition 28.10.1. For measurable spaces $(X, \mathcal{A})$ and $(Y, \mathcal{B})$, the *product σ-algebra* $\mathcal{A} \otimes \mathcal{B}$ on $X \times Y$ is generated by the *rectangles* $A \times B$. For $E \subseteq X \times Y$, the sections are $E_x = \{y : (x, y) \in E\}$ and $E^y = \{x : (x, y) \in E\}$.

Theorem 28.10.2. *Let μ and ν be σ-finite measures on X and Y. For $E \in \mathcal{A} \otimes \mathcal{B}$, the sections are measurable, the functions $x \mapsto \nu(E_x)$ and $y \mapsto \mu(E^y)$ are measurable, and*

$$(\mu \times \nu)(E) = \int \nu(E_x)\, d\mu(x) = \int \mu(E^y)\, d\nu(y)$$

defines the unique measure on $\mathcal{A} \otimes \mathcal{B}$ with $(\mu \times \nu)(A \times B) = \mu(A)\nu(B)$.

Proof. Assume first that μ and ν are finite. The sets E for which all claims hold (including equality of the two integrals) contain the rectangles, which are closed under finite intersections, and they are closed under complements and countable disjoint unions (by additivity and monotone convergence). Measurability of sections holds for all $E \in \mathcal{A} \otimes \mathcal{B}$ since the sets with measurable sections form a σ-algebra. By Lemma 28.3.10 the claims hold on $\mathcal{A} \otimes \mathcal{B}$, and countable additivity follows from monotone convergence. For σ-finite measures write $X \times Y$ as an increasing union of $X_m \times Y_m$ with finite measures and pass to the limit. Uniqueness follows from Lemma 28.3.10. □

Theorem 28.10.3 (Tonelli and Fubini)**.** *Let μ, ν be σ-finite.*

1. *If $f : X \times Y \to [0, \infty]$ is measurable, then $x \mapsto \int f(x, y)\, d\nu(y)$ is measurable and $\int_{X \times Y} f\, d(\mu \times \nu) = \int \left(\int f(x, y)\, d\nu(y) \right) d\mu(x) = \int \left(\int f(x, y)\, d\mu(x) \right) d\nu(y)$.*
2. *If $f \in L^1(\mu \times \nu)$, then $f(x, -) \in L^1(\nu)$ for a.e. x, the function $x \mapsto \int f(x, y)\, d\nu(y)$ (defined a.e.) is integrable, and the same equalities hold.*

Proof. (1) For indicator functions this is Theorem 28.10.2; it extends to simple functions by linearity and to all $f \geq 0$ by monotone convergence. (2) Apply (1) to $|f|$ to see that $\int |f(x, y)|\, d\nu(y) < \infty$ for a.e. x, and then to the positive and negative parts of the real and imaginary parts. □

Counterexample 28.10.4. Integrability is needed in (2). On $\mathbb{N} \times \mathbb{N}$ with counting measures let $f(n, n) = 1$, $f(n, n + 1) = -1$ and $f = 0$ otherwise. Then $\sum_m \sum_n f(n, m) = 1$, since only column $m = 0$ has nonzero sum, whereas $\sum_n \sum_m f(n, m) = 0$.

Remark 28.10.5. λ^{m+n} and $\lambda^m \times \lambda^n$ agree on boxes, hence on Borel sets by Lemma 28.3.10, and λ^{m+n} is the completion of $\lambda^m \times \lambda^n$. So Fubini's theorem applies to Lebesgue measure on $\mathbb{R}^{m+n} = \mathbb{R}^m \times \mathbb{R}^n$ for Borel functions, and for Lebesgue measurable functions with "for almost every x" qualifications.

Proposition 28.10.6 (Layer cake formula)**.** *Let μ be a σ-finite measure on X and $f : X \to [0, \infty]$ measurable. Then*

$$\int_X f\, d\mu = \int_0^\infty \mu(\{f > t\})\, dt.$$

More generally, if $\psi : [0, \infty) \to [0, \infty)$ is Borel measurable and $\phi(s) = \int_0^s \psi(t)\, dt$ (with $\phi(\infty) = \int_0^\infty \psi$), then $\int_X \phi \circ f\, d\mu = \int_0^\infty \psi(t)\, \mu(\{f > t\})\, dt$; in particular $\int_X f^p\, d\mu = p \int_0^\infty t^{p-1} \mu(\{f > t\})\, dt$ for $p > 0$.

Proof. The set $E = \{(x,t) \in X \times [0,\infty) : t < f(x)\}$ is measurable for the product σ-algebra, because $t < f(x)$ holds exactly when $t < q < f(x)$ for some rational q, so $E = \bigcup_{q\in\mathbb{Q}_{>0}} \{f > q\} \times [0,q)$. Apply Tonelli's theorem (Theorem 28.10.3(1)) to the non-negative measurable function $(x,t) \mapsto \psi(t)\mathbf{1}_E(x,t)$ on $X \times [0,\infty)$ with $\mu\times\lambda$. Integrating first in t gives $\int_0^{f(x)} \psi(t)\,dt = \phi(f(x))$, integrating first in x gives $\psi(t)\mu(\{f > t\})$. The first formula is the case $\psi = 1$, and the last one the case $\psi(t) = pt^{p-1}$. □

The name describes the picture: the region under the graph of f is cut into horizontal layers $\{f > t\}$ of thickness dt. As an application we show that the maximal function of an L^p function is in L^p for $p > 1$, although it is never in L^1 (Exercise 28.23.4).

Corollary 28.10.7 (Hardy–Littlewood maximal theorem)**.** *For $1 < p \le \infty$ and $f \in L^p(\mathbb{R}^n)$, $\|Mf\|_p \le C_{n,p}\|f\|_p$, with $C_{n,\infty} = 1$ and $C_{n,p}^p = 2^p 3^n p/(p-1)$.*

Proof. For $p = \infty$, every average of $|f|$ is at most $\|f\|_\infty$. Let $p < \infty$ and $t > 0$, and split $f = f_1 + f_2$ with $f_1 = f\mathbf{1}_{\{|f|>t/2\}}$. Then $f_1 \in L^1$, since $|f_1| \le (2/t)^{p-1}|f|^p$, and $Mf \le Mf_1 + Mf_2 \le Mf_1 + t/2$, so $\{Mf > t\} \subseteq \{Mf_1 > t/2\}$, and by Theorem 28.9.3, $\lambda(\{Mf > t\}) \le \frac{2\cdot 3^n}{t}\int_{\{|f|>t/2\}} |f|$. By Proposition 28.10.6 and Tonelli's theorem,

$$\int (Mf)^p = p\int_0^\infty t^{p-1}\lambda(\{Mf > t\})\,dt \le 2\cdot 3^n p \int |f(x)| \int_0^{2|f(x)|} t^{p-2}\,dt\,d\lambda(x) = \frac{2\cdot 3^n p}{p-1}\int |f|(2|f|)^{p-1},$$

which is $\frac{2^p 3^n p}{p-1}\|f\|_p^p$. □

28.11 Change of variables

Lemma 28.11.1. *For $T \in \mathrm{GL}_n(\mathbb{R})$ and Borel $E \subseteq \mathbb{R}^n$, $\lambda(T(E)) = |\det T|\,\lambda(E)$.*

Proof. Both sides are multiplicative in T, and every invertible matrix is a product of *elementary* matrices (by Gaussian elimination): permutations of coordinates, scalings of one coordinate by $c \ne 0$, and shears $x_i \mapsto x_i + cx_j$ $(i \ne j)$. Permutations and scalings map boxes to boxes, multiplying volumes by $|\det T|$, so they multiply outer measure by $|\det T|$. A shear preserves each line parallel to the i-th axis and acts on it by a translation; by Theorem 28.10.3 and Remark 28.10.5, integrating the one-dimensional measures of these sections shows $\lambda(T(E)) = \lambda(E)$, and $\det T = 1$. □

Theorem 28.11.2 (Change of variables)**.** *Let $U, V \subseteq \mathbb{R}^n$ be open and $\phi\colon U \to V$ a C^1-diffeomorphism. For every measurable $f : V \to [0,\infty]$, and every $f \in L^1(V)$,*

$$\int_V f\,d\lambda = \int_U f(\phi(x))\,|\det D\phi(x)|\,d\lambda(x).$$

Proof. We use the norm $\|x\|_\infty$ and the corresponding operator norm; the mean value inequality (Proposition 27.10.3(4)) holds for it with the same proof. Cubes are balls $Q = \{x : \|x-a\|_\infty \le h\}$.

Step 1. Let $Q \subseteq U$ be a cube with centre a and $T \in \mathrm{GL}_n(\mathbb{R})$, and let $M = \sup_{y\in Q} \|T^{-1}D\phi(y)\|$. By the mean value inequality applied to $T^{-1}\phi$, $\phi(Q) \subseteq \phi(a) + T(\{\|z\|_\infty \le Mh\})$, so $\lambda(\phi(Q)) \le |\det T|M^n\lambda(Q)$ by Lemma 28.11.1.

Step 2: $\lambda(\phi(Q)) \le \int_Q |\det D\phi|$ for cubes $Q \subseteq U$. Let $\varepsilon > 0$. Since $D\phi$ is uniformly continuous on Q and $\|D\phi^{-1}\|$ is bounded there, we can divide Q into subcubes Q_j with centres x_j such that $\|D\phi(x_j)^{-1}D\phi(y)\| \le 1 + \varepsilon$ for $y \in Q_j$, and $|\det D\phi|$ varies by less than ε on each Q_j. Step 1 with $T = D\phi(x_j)$ gives $\lambda(\phi(Q)) \le \sum_j \lambda(\phi(Q_j)) \le (1+\varepsilon)^n \sum_j |\det D\phi(x_j)|\lambda(Q_j) \le (1+\varepsilon)^n(\int_Q |\det D\phi| + \varepsilon\lambda(Q))$.

Step 3: $\lambda(\phi(E)) \le \int_E |\det D\phi|$ *for measurable* $E \subseteq U$. An open $W \subseteq U$ is a countable union of cubes with disjoint interiors (dyadic cubes), whose boundaries are null, so the inequality holds for W. Let $E \subseteq K$ with $K \subseteq U$ compact, and $C = \sup$ of $|\det D\phi|$ on a compact neighbourhood $N \subseteq U$ of K. By regularity choose open W with $E \subseteq W \subseteq N$ and $\lambda(W \setminus E) < \delta$; then $\lambda(\phi(E)) \le \lambda(\phi(W)) \le \int_E |\det D\phi| + C\delta$. This shows that ϕ maps null sets to null sets, hence Lebesgue measurable sets to Lebesgue measurable sets (a measurable set is a Borel set up to a null set), and gives the inequality for E in a compact subset; exhaust U by compact sets for general E.

Step 4. By Step 3, $\int_V \mathbf{1}_{\phi(E)} \le \int_U \mathbf{1}_{\phi(E)} \circ \phi\, |\det D\phi|$; by linearity and monotone convergence, $\int_V f \le \int_U (f \circ \phi)|\det D\phi|$ for all measurable $f \ge 0$. Applying this to ϕ^{-1} and the function $(f \circ \phi)|\det D\phi|$ on U, and using $D\phi(\phi^{-1}(y))D(\phi^{-1})(y) = 1$, gives the reverse inequality. The L^1 case follows by linearity. □

Example 28.11.3. With polar coordinates $(r, \theta) \mapsto (r\cos\theta, r\sin\theta)$, a diffeomorphism $(0,\infty)\times(0,2\pi) \to \mathbb{R}^2$ minus a closed half-line (a null set), with Jacobian determinant r, Tonelli's theorem gives $(\int_{\mathbb{R}} e^{-x^2}dx)^2 = \int_{\mathbb{R}^2} e^{-\|x\|^2} = \int_0^{2\pi}\int_0^\infty e^{-r^2} r\, dr\, d\theta = \pi$. So $\int_{\mathbb{R}} e^{-x^2}\, dx = \sqrt{\pi}$.

Fubini's theorem reduces integration by parts in several variables to one variable. When one of the functions has compact support there is no boundary term.

Proposition 28.11.4 (Integration by parts in $\mathbb{R}^n$)**.** *Let* $f, g\colon \mathbb{R}^n \to \mathbb{C}$ *be continuously differentiable, and suppose that one of them has compact support. Then for each* i

$$\int_{\mathbb{R}^n} (\partial_i f)\, g\, d\lambda = -\int_{\mathbb{R}^n} f\, \partial_i g\, d\lambda.$$

Consequently, for a continuously differentiable vector field F *and a continuously differentiable function* g*, one of them compactly supported,* $\int \operatorname{div} F\, g\, d\lambda = -\int \langle F, \nabla g\rangle\, d\lambda$*, where* $\operatorname{div} F = \sum_i \partial_i F^i$ *and* $\nabla g = (\partial_1 g, \dots, \partial_n g)$*; and for* f *of class* C^2*,* $\int (\sum_i \partial_i^2 f)\, g\, d\lambda = -\int \langle \nabla f, \nabla g\rangle\, d\lambda$.

Proof. The product $h = fg$ is continuously differentiable with compact support, contained in a cube $[-R,R]^n$, and $\partial_i h = (\partial_i f)g + f\,\partial_i g$ by the product rule; all these functions are continuous with compact support, hence integrable. By Fubini's theorem (Theorem 28.10.3) we may integrate first in the variable x_i, the others being fixed. For fixed values of the other variables, $t \mapsto h(\dots, t, \dots)$ is continuously differentiable and vanishes for $|t| \ge R$, so by the fundamental theorem of calculus (Theorem 27.8.3) $\int_{-R}^{R} \partial_i h\, dx_i = h(\dots, R, \dots) - h(\dots, -R, \dots) = 0$. Hence $\int \partial_i h\, d\lambda = 0$, which is the formula. For the vector field, apply it to F^i and g and sum over i; for the last formula take $F = \nabla f$. □

The formula says that the operator ∂_i is *anti-self-adjoint* for the L^2 inner product on compactly supported functions: $\langle \partial_i f, \bar g\rangle = -\langle f, \partial_i \bar g\rangle$. It is the reason why the derivative of a distribution is defined by $(\partial_i T)(\varphi) = -T(\partial_i \varphi)$ (Chapter 32), and, applied twice, it shows that $-\sum_i \partial_i^2$ is a non-negative operator: $\int (-\sum_i \partial_i^2 f)\bar f\, d\lambda = \int |\nabla f|^2\, d\lambda \ge 0$ for compactly supported f of class C^2.

28.11.1 Volumes: Cavalieri's principle and solids of revolution

Fubini's theorem and the change of variables formula contain the classical recipes for computing volumes. We write λ^n for Lebesgue measure on $\mathbb{R}^n$ and call $\lambda^3(E)$ the *volume* and $\lambda^2(E)$ the *area* of a set. The first recipe slices a solid by parallel planes.

Proposition 28.11.5 (Cavalieri's principle)**.** *Let $E \subseteq \mathbb{R}^n = \mathbb{R}^{n-1} \times \mathbb{R}$ be a Borel set, and for $t \in \mathbb{R}$ let $E_t = \{y \in \mathbb{R}^{n-1} : (y,t) \in E\}$ be its slice at height t. Then $t \mapsto \lambda^{n-1}(E_t)$ is measurable and*

$$\lambda^n(E) = \int_{\mathbb{R}} \lambda^{n-1}(E_t)\, dt.$$

In particular, two Borel sets whose slices at every height have the same $(n-1)$-dimensional measure have the same volume.

Proof. Apply Tonelli's theorem (Theorem 28.10.3(1)) to the indicator function $\mathbf{1}_E$ on $\mathbb{R}^{n-1} \times \mathbb{R}$, with $\lambda^n = \lambda^{n-1} \times \lambda^1$ on Borel sets (Remark 28.10.5), integrating first over y: $\int \mathbf{1}_E(y,t)\, d\lambda^{n-1}(y) = \lambda^{n-1}(E_t)$. □

The principle is named after Bonaventura Cavalieri (1635), who stated it for plane figures and solids, but Archimedes had already used it, and Zu Chongzhi and his son Zu Geng used it in China in the fifth century to find the volume of the ball.

Example 28.11.6.

1. *Cones.* Let $B \subseteq \mathbb{R}^2$ be a Borel set of finite area A and $h > 0$, and let C be the cone over B with apex $(0,0,h)$, the union of the segments from the points of $B \times \{0\}$ to the apex. Its slice at height $t \in [0,h)$ is the scaled copy $(1-t/h)B$, of area $(1-t/h)^2 A$ by Lemma 28.11.1. So $\lambda^3(C) = A\int_0^h (1-t/h)^2\, dt = \frac{1}{3}Ah$, whatever the shape of the base: a third of the prism with the same base and height.

2. *Archimedes' ball.* The slice of the half-ball $\{|x| \le R, x_3 \ge 0\}$ at height $t \in [0,R]$ is a disc of area $\pi(R^2 - t^2)$. The slice of the cylinder $\{x_1^2 + x_2^2 \le R^2, 0 \le x_3 \le R\}$ minus the cone $\{\sqrt{x_1^2 + x_2^2} < x_3\}$ is an annulus of area $\pi R^2 - \pi t^2$. The slices have equal areas, so the half-ball has the volume of the cylinder minus the cone, $\pi R^3 - \frac{1}{3}\pi R^3 = \frac{2}{3}\pi R^3$, and the ball has volume $\frac{4}{3}\pi R^3$. This is Archimedes' argument, which he regarded as his finest: the ball is two thirds of the circumscribed cylinder.

A *solid of revolution* is obtained by rotating a plane region around an axis. We take the z-axis in $\mathbb{R}^3$ as axis, and describe the region in the half-plane $H = \{(r,z) : r > 0\}$ of distances from the axis and heights. For a Borel set $R \subseteq H$ let

$$\mathrm{Rev}(R) = \left\{(x,y,z) \in \mathbb{R}^3 : \left(\sqrt{x^2+y^2}, z\right) \in R\right\}$$

be the solid swept out by R, a Borel set since it is the preimage of R under a continuous map on $\mathbb{R}^3$ minus the axis.

Proposition 28.11.7 (Volumes of solids of revolution)**.** *For every Borel set $R \subseteq H$,*

$$\lambda^3(\mathrm{Rev}(R)) = 2\pi \int_R r\, d\lambda^2(r,z).$$

In particular:

1. *(*Discs*) if $R = \{(r,z) : a \le z \le b,\ 0 < r \le f(z)\}$ for a continuous $f \ge 0$ on $[a,b]$, then $\lambda^3(\mathrm{Rev}(R)) = \pi \int_a^b f(z)^2\, dz$;*

2. *(*Shells*) if $R = \{(r,z) : a \le r \le b,\ 0 \le z \le g(r)\}$ for $0 < a < b$ and a continuous $g \ge 0$ on $[a,b]$, then $\lambda^3(\mathrm{Rev}(R)) = 2\pi \int_a^b r g(r)\, dr$.*

Proof. Use *cylindrical coordinates* $\phi(r,\theta,z) = (r\cos\theta, r\sin\theta, z)$, a C^1-diffeomorphism from $U = (0,\infty)\times(0,2\pi)\times\mathbb{R}$ onto $\mathbb{R}^3$ minus the closed half-plane $\{y = 0, x \geq 0\}$, which is a null set. Its Jacobian determinant is

$$\det\begin{pmatrix}\cos\theta & -r\sin\theta & 0\\ \sin\theta & r\cos\theta & 0\\ 0 & 0 & 1\end{pmatrix} = r.$$

Since $\mathbf{1}_{\mathrm{Rev}(R)}(\phi(r,\theta,z)) = \mathbf{1}_R(r,z)$, the change of variables formula (Theorem 28.11.2) and Tonelli's theorem give $\lambda^3(\mathrm{Rev}(R)) = \int_U \mathbf{1}_R(r,z)\, r\, d\lambda^3 = \int_0^{2\pi} d\theta \int_R r\, d\lambda^2 = 2\pi\int_R r\, d\lambda^2$. For (1), integrate first over r: $\int_0^{f(z)} r\, dr = \frac{1}{2}f(z)^2$. For (2), integrate first over z: $\int_0^{g(r)} dz = g(r)$. □

The two special cases are the "disc method" and the "shell method" of calculus courses: (1) cuts the solid by planes perpendicular to the axis, which meet it in discs of area $\pi f(z)^2$, and is also a case of Cavalieri's principle; (2) cuts it into thin cylindrical shells of radius r, height $g(r)$ and thickness dr, of volume $2\pi r g(r)\, dr$. For the ball, (1) with $f(z) = \sqrt{R^2 - z^2}$ gives $\pi\int_{-R}^{R}(R^2 - z^2)\, dz = \frac{4}{3}\pi R^3$ once more.

The integral $\int_R r\, d\lambda^2$ has a mechanical meaning. The *centroid* of a Borel set $R \subseteq \mathbb{R}^2$ of finite positive area is the point $(\bar r, \bar z)$ with $\bar r = \lambda^2(R)^{-1}\int_R r\, d\lambda^2$ and $\bar z = \lambda^2(R)^{-1}\int_R z\, d\lambda^2$, its centre of mass for a uniform density. So the proposition can be read as follows.

Corollary 28.11.8 (Pappus–Guldin theorem for volumes)**.** *If $R \subseteq H$ has finite positive area and centroid at distance $\bar r$ from the axis, then*

$$\lambda^3(\mathrm{Rev}(R)) = 2\pi\bar r\cdot\lambda^2(R)\,:$$

the volume of a solid of revolution is the area of the region times the length of the circle described by its centroid.

Proof. $2\pi\int_R r\, d\lambda^2 = 2\pi\bar r\lambda^2(R)$ by the definition of $\bar r$. □

The theorem was stated by Pappus of Alexandria around 320 and rediscovered by Paul Guldin in 1640; in Italian it is the *teorema di Pappo–Guldino*. It turns volume computations into centroid computations, and conversely.

Example 28.11.9.

1. *The torus.* Rotating the disc of radius a centred at $(c,0)$, with $0 < a < c$, gives a solid torus. The centroid is the centre, by symmetry, so the volume is $2\pi c\cdot\pi a^2 = 2\pi^2 c a^2$: the volume of a cylinder of radius a whose length is the central circle of the torus. Computing it with discs requires the integral $\int_{-a}^{a}\pi\big((c+\sqrt{a^2-z^2})^2 - (c-\sqrt{a^2-z^2})^2\big)dz = 4\pi c\int_{-a}^{a}\sqrt{a^2-z^2}\, dz$, which is the same thing, $4\pi c\cdot\frac{1}{2}\pi a^2$.

2. *The centroid of a half-disc.* Conversely, rotating the half-disc $\{r^2 + z^2 \leq a^2, r > 0\}$ around the z-axis gives the ball of radius a, so $\frac{4}{3}\pi a^3 = 2\pi\bar r\cdot\frac{1}{2}\pi a^2$, and the centroid of a half-disc lies at distance $\bar r = \frac{4a}{3\pi}$ from its diameter.

28.12 The Radon–Nikodym and Riesz representation theorems

Lemma 28.12.1. *Let H be a complex inner product space that is complete (a* Hilbert space*), for instance $L^2(\mu)$. Every continuous linear functional $\Lambda\colon H \to \mathbb{C}$ is of the form $\Lambda(f) = \langle f, g\rangle$ for a unique $g \in H$.*

Proof. If $\Lambda = 0$ take $g = 0$. Otherwise $N = \ker \Lambda$ is a closed proper subspace. Choose $u \notin N$ and let $d = \inf_{v \in N} \|u - v\| > 0$. For $v_k \in N$ with $\|u - v_k\| \to d$, the parallelogram law $\|v_k - v_l\|^2 = 2\|u - v_k\|^2 + 2\|u - v_l\|^2 - 4\|u - \frac{v_k + v_l}{2}\|^2$ shows that (v_k) is Cauchy; its limit v satisfies $\|u - v\| = d$. For $w \in N$ and $t \in \mathbb{C}$, $\|u - v - tw\|^2 \geq d^2$ forces $\langle u - v, w\rangle = 0$. So $z = u - v \neq 0$ is orthogonal to N. For $f \in H$, $\Lambda(f)z - \Lambda(z)f \in N$, so $\Lambda(f)\|z\|^2 = \Lambda(z)\langle f, z\rangle$, and $g = \overline{\Lambda(z)}z/\|z\|^2$ works. Uniqueness: if $\langle f, g - g'\rangle = 0$ for all f, take $f = g - g'$. □

Theorem 28.12.2 (Radon–Nikodym)**.** *Let μ and ν be σ-finite measures on $(X, \mathcal{A})$ with $\nu \ll \mu$, meaning $\mu(E) = 0 \Rightarrow \nu(E) = 0$. There is a measurable $h \geq 0$, unique a.e., with $\nu(E) = \int_E h \, d\mu$ for all E.*

Proof. Assume μ and ν finite; the σ-finite case follows by decomposing X. Let $\rho = \mu + \nu$. On $L^2(\rho)$, $f \mapsto \int f \, d\nu$ is continuous, since $|\int f \, d\nu| \leq \int |f| \, d\rho \leq \rho(X)^{1/2}\|f\|_2$. By Lemma 28.12.1 there is g with $\int f \, d\nu = \int f g \, d\rho$ for all $f \in L^2(\rho)$, and g may be taken real. Taking $f = \mathbf{1}_E$ gives $\nu(E) = \int_E g \, d\rho$, so $g \geq 0$ ρ-a.e.; and $\int_E (1 - g) \, d\nu = \int_E g \, d\mu$ (for bounded f, $\int f(1 - g) \, d\nu = \int f g \, d\mu$). For $E = \{g \geq 1\}$ the left side is ≤ 0 and the right side is $\geq \mu(E)$, so $\mu(E) = 0$ and $\nu(E) = 0$. Applying the identity to $f = \mathbf{1}_E(1 + g + \cdots + g^k)$ gives $\int_E (1 - g^{k+1}) \, d\nu = \int_E (g + \cdots + g^{k+1}) \, d\mu$. As $k \to \infty$, monotone convergence gives $\nu(E) = \int_E h \, d\mu$ with $h = g/(1 - g)$. If h' also works, $\int_E (h - h') \, d\mu = 0$ for $E = \{h > h'\}$ and $\{h < h'\}$ (intersected with sets of finite measure), so $h = h'$ a.e. □

Two measures μ, ν on $(X, \mathcal{A})$ are *mutually singular*, $\nu \perp \mu$, if there is $S \in \mathcal{A}$ with $\mu(S) = 0$ and $\nu(X \setminus S) = 0$: they live on disjoint sets.

Theorem 28.12.3 (Lebesgue decomposition)**.** *Let μ, ν be σ-finite measures on $(X, \mathcal{A})$. There are unique measures $\nu_a \ll \mu$ and $\nu_s \perp \mu$ with $\nu = \nu_a + \nu_s$; and $\nu_a = h\,\mu$ for a measurable $h \geq 0$.*

Proof. As in Theorem 28.12.2 we may assume μ, ν finite. Let $\rho = \mu + \nu$. Since $\nu \ll \rho$, Theorem 28.12.2 gives $g \geq 0$ with $\nu(E) = \int_E g \, d\rho$; from $\nu(E) \leq \rho(E)$ for all E, $g \leq 1$ ρ-almost everywhere, and we may take $0 \leq g \leq 1$. Writing $\int_E g \, d\rho = \int_E g \, d\mu + \int_E g \, d\nu$ gives

$$\int_E (1 - g) \, d\nu = \int_E g \, d\mu \qquad (E \in \mathcal{A}).$$

Let $S = \{g = 1\}$. For $E = S$ the left side vanishes, so $\int_S g \, d\mu = \mu(S) = 0$. Put $\nu_s(E) = \nu(E \cap S)$ and $\nu_a(E) = \nu(E \setminus S)$; then $\nu_s \perp \mu$. If $\mu(E) = 0$, the identity gives $\int_E (1 - g) \, d\nu = 0$, so $1 - g = 0$ ν-almost everywhere on E, that is, $\nu(E \setminus S) = 0$: $\nu_a \ll \mu$, and $\nu_a = h\,\mu$ by Theorem 28.12.2. For uniqueness, let $\nu = \nu_a' + \nu_s'$ be another decomposition, with ν_s' living on a μ-null set S'. On subsets of $X \setminus (S \cup S')$ both singular parts vanish, so $\nu_a = \nu = \nu_a'$; on subsets of the μ-null set $S \cup S'$ both absolutely continuous parts vanish. Hence $\nu_a = \nu_a'$, and $\nu_s = \nu - \nu_a = \nu_s'$ (ν being finite). □

Example 28.12.4. With respect to Lebesgue measure λ on $\mathbb{R}$: $\nu = \delta_0 + \mathbf{1}_{[0,1]}\lambda$ has $\nu_a = \mathbf{1}_{[0,1]}\lambda$ and $\nu_s = \delta_0$, living on $\{0\}$. The measure μ_F of the Cantor function (Lemma 28.13.3) is singular, living on the Cantor set, but has no atoms. In general the singular part splits further into a *discrete* part, a countable sum of point masses, and a *singular continuous* part without atoms, like μ_F: the atoms of a σ-finite measure form a countable set, and the discrete part is the restriction to it.

28.13 Absolutely continuous functions

By Corollary 28.9.6, an indefinite integral $F(x) = F(a) + \int_a^x f$ of an integrable function satisfies $F' = f$ almost everywhere. Conversely, when is a function the integral of its derivative? Continuity and differentiability almost everywhere are not enough, by the Cantor function (Counterexample 28.9.7). The right condition is absolute continuity.

Definition 28.13.1. A function $F\colon [a,b] \to \mathbb{C}$ is *absolutely continuous* if for every $\varepsilon > 0$ there is $\delta > 0$ such that $\sum_k |F(b_k) - F(a_k)| < \varepsilon$ for every finite family of pairwise disjoint intervals $(a_k, b_k) \subseteq [a,b]$ with $\sum_k (b_k - a_k) < \delta$. For real F, the *total variation* of F on $[a,x]$ is $V_F(x) = \sup \sum_i |F(t_i) - F(t_{i-1})|$, the supremum over the partitions $a = t_0 < \cdots < t_m = x$.

Lemma 28.13.2. *1. For $f \in L^1([a,b])$, $F(x) = \int_{[a,x]} f\,d\lambda$ is absolutely continuous; more precisely, for every $\varepsilon > 0$ there is $\delta > 0$ with $\int_E |f| < \varepsilon$ whenever $\lambda(E) < \delta$.*

2. If F is real and absolutely continuous, then V_F is finite, nondecreasing and absolutely continuous, and so is $V_F - F$. So $F = V_F - (V_F - F)$ is a difference of nondecreasing absolutely continuous functions.

Proof. (1) By monotone convergence $\int_{\{|f|>N\}} |f| \to 0$ as $N \to \infty$; choose N with $\int_{\{|f|>N\}} |f| < \varepsilon/2$ and $\delta = \varepsilon/(2N)$. Then $\int_E |f| \le \int_{\{|f|>N\}} |f| + N\lambda(E) < \varepsilon$. For disjoint intervals of total length $< \delta$, $\sum_k |F(b_k) - F(a_k)| \le \int_{\bigcup_k (a_k,b_k)} |f| < \varepsilon$.

(2) Take δ for $\varepsilon = 1$ and cut $[a,b]$ into N intervals of length $< \delta$; refining a partition by these cut points does not decrease the sum, and the sum over each of the N intervals is < 1, so $V_F(b) \le N$. For $x < y$, $V_F(y) - V_F(x)$ is the total variation of F on $[x,y]$ (a partition of $[a,y]$ refined by x splits into partitions of $[a,x]$ and $[x,y]$), so V_F is nondecreasing and $V_F(y) - V_F(x) \ge |F(y) - F(x)| \ge F(y) - F(x)$, which makes $V_F - F$ nondecreasing. If (a_k, b_k) are disjoint with $\sum_k (b_k - a_k) < \delta$ for the δ of ε, then any partitions of the intervals $[a_k, b_k]$ together give disjoint intervals of total length $< \delta$, so $\sum_k (V_F(b_k) - V_F(a_k)) \le \varepsilon$: V_F is absolutely continuous, and so is $V_F - F$. □

Lemma 28.13.3. *Let $F\colon [a,b] \to \mathbb{R}$ be continuous and nondecreasing. There is a finite Borel measure μ_F on $[a,b]$ with $\mu_F([a,x]) = F(x) - F(a)$ for all x; so $\mu_F((x,y]) = F(y) - F(x)$ and points have measure 0. If F is absolutely continuous, then μ_F is absolutely continuous with respect to λ.*

Proof. Let $c = F(a)$ and $d = F(b)$. For $t \in [c,d]$ the set $\{x : F(x) = t\}$ is nonempty by the intermediate value theorem and closed, so it has a least element $G(t)$. The map $G\colon [c,d] \to [a,b]$ is nondecreasing, hence Borel measurable (preimages of intervals are intervals), and $G(t) \le x$ if and only if $t \le F(x)$: if $t \le F(x)$ some $y \le x$ has $F(y) = t$, and if $G(t) \le x$ then $t = F(G(t)) \le F(x)$. Let $\mu_F(E) = \lambda(\{t \in [c,d] : G(t) \in E\})$ for Borel $E \subseteq [a,b]$, the image of Lebesgue measure under G. Then $\mu_F([a,x]) = \lambda([c, F(x)]) = F(x) - c$.

Let F be absolutely continuous and E a Borel set with $\lambda(E) = 0$. Given $\varepsilon > 0$, take δ from the definition and an open $U \supseteq E$ with $\lambda(U) < \delta$ (Theorem 28.3.4). The open set $U \cap (a,b)$ is the disjoint union of countably many open intervals (a_k, b_k), its connected components, with $\sum_k (b_k - a_k) < \delta$. For every N, $\sum_{k \le N} \mu_F((a_k, b_k)) = \sum_{k \le N} (F(b_k) - F(a_k)) < \varepsilon$, so $\mu_F(U \cap (a,b)) \le \varepsilon$ and $\mu_F(E) \le \varepsilon$, the endpoints a, b having measure 0. As ε is arbitrary, $\mu_F(E) = 0$. □

Theorem 28.13.4 (Fundamental theorem of calculus for absolutely continuous functions)**.** *Let $F\colon [a,b] \to \mathbb{C}$ be absolutely continuous. Then F is differentiable almost everywhere, $F' \in L^1([a,b])$, and*

$$F(x) = F(a) + \int_a^x F'(t)\,dt \qquad \text{for all } x \in [a,b].$$

Conversely, every function of the form $F(a) + \int_a^x f$ with $f \in L^1([a,b])$ is absolutely continuous. So the absolutely continuous functions are exactly the indefinite Lebesgue integrals.

Proof. The converse is Lemma 28.13.2(1). For the direct statement, treat real and imaginary parts separately, and by Lemma 28.13.2(2) assume that F is nondecreasing, the statement being linear in F. By Lemma 28.13.3, μ_F is a finite measure with $\mu_F \ll \lambda$ on the Borel sets of $[a,b]$, so by the Radon–Nikodym theorem (Theorem 28.12.2) there is an integrable $h \geq 0$ with $\mu_F(E) = \int_E h\, d\lambda$. Hence $F(x) - F(a) = \mu_F([a,x]) = \int_a^x h$, and by Corollary 28.9.6, F is differentiable almost everywhere with $F' = h$. □

Example 28.13.5. A Lipschitz function, $|F(x) - F(y)| \leq L|x-y|$, is absolutely continuous (take $\delta = \varepsilon/L$), so it is differentiable almost everywhere and is the integral of its derivative; for instance $|x| = \int_0^x \operatorname{sgn}$. The Cantor function is continuous and nondecreasing but not absolutely continuous: it maps the Cantor set, of measure 0, onto $[0,1]$, whereas the proof of Lemma 28.13.3 shows that an absolutely continuous nondecreasing function gives measure 0 to null sets, and $\mu_F(C) = F(1) - F(0) = 1$ for the Cantor function because F is constant on the complement of C. The function $x \sin(1/x)$ (and 0 at 0) on $[0,1]$ is continuous but not of bounded variation, hence not absolutely continuous.

28.14 Radon measures and the Riesz representation theorem

A measure assigns numbers to sets; integration against it assigns numbers to functions, $f \mapsto \int f\, d\mu$, and this assignment is linear and positive. On $\mathbb{R}^n$ the Riemann integral of continuous functions with compact support is such an assignment, and Lebesgue measure can be recovered from it: $\lambda([0,1]^n)$ is the infimum of the integrals of the continuous functions that are at least 1 on the cube. The Riesz representation theorem says that this always works: every positive linear functional on continuous functions with compact support is integration against exactly one measure of a reasonable kind. This point of view, *measures as linear functionals*, is basic in geometric measure theory, in probability and in the theory of partial differential equations. It allows one to take limits of measures (Section 28.15), and it is the model for distributions, which are linear functionals on smooth functions (Chapter 32).

Throughout this section X is a locally compact Hausdorff space with a countable basis; for instance $\mathbb{R}^n$, an open or a closed subset of $\mathbb{R}^n$, or a manifold. Such a space is metrisable: it is regular, because for a point x outside a closed set F, Lemma 18.9.5 applied to $\{x\} \subseteq X \setminus F$ gives an open $V \ni x$ with $\overline{V} \cap F = \emptyset$, and a regular space with a countable basis is metrisable (Theorem 18.8.8). It has an exhaustion by compact sets $K_1 \subseteq K_2 \subseteq \cdots$ with $K_m \subseteq \operatorname{int} K_{m+1}$ (Proposition 18.10.7); every compact $K \subseteq X$ lies in some K_m, since the increasing open sets $\operatorname{int} K_m$ cover K.

We write $C_c(X)$ for the real vector space of continuous functions $f : X \to \mathbb{R}$ with compact support, and, for an open $V \subseteq X$,

$$f \prec V \quad \text{if} \quad f \in C_c(X), \quad 0 \leq f \leq 1 \quad \text{and} \quad \operatorname{supp} f \subseteq V.$$

Continuous functions are Borel measurable. If μ is a Borel measure that is finite on compact sets, every $f \in C_c(X)$ is integrable, with $|\int f\, d\mu| \leq \|f\|_\infty\, \mu(\operatorname{supp} f)$.

Lemma 28.14.1. *Let ν be a finite Borel measure on a metrisable space X. For every Borel set E and every $\varepsilon > 0$ there are a closed set F and an open set U with $F \subseteq E \subseteq U$ and $\nu(U \setminus F) < \varepsilon$.*

Proof. Fix a metric d inducing the topology, and let $\mathcal{G}$ be the family of Borel sets E with the stated property. A closed set E belongs to $\mathcal{G}$: take $F = E$ and $U_k = \{x : d(x,E) < 1/k\}$, which are open, decrease, and have intersection E because E is closed; as ν is finite, $\nu(U_k \setminus E) \to 0$

(Proposition 28.2.4). The family $\mathcal{G}$ is closed under complements, since $F \subseteq E \subseteq U$ gives $X \setminus U \subseteq X \setminus E \subseteq X \setminus F$ with the same difference $U \setminus F$. It is closed under countable unions: if $F_k \subseteq E_k \subseteq U_k$ with $\nu(U_k \setminus F_k) < \varepsilon 2^{-k-1}$, then $U = \bigcup_k U_k$ is open and $F' = \bigcup_k F_k$ satisfies $\nu(U \setminus F') < \varepsilon/2$; the closed sets $F_1 \cup \cdots \cup F_N$ increase to F', so one of them, F, has $\nu(F' \setminus F) < \varepsilon/2$, and then $F \subseteq \bigcup_k E_k \subseteq U$ and $\nu(U \setminus F) < \varepsilon$. So $\mathcal{G}$ is a σ-algebra containing the closed sets, hence all Borel sets. □

Proposition 28.14.2. *Let X be a locally compact Hausdorff space with a countable basis and μ a Borel measure on X that is finite on compact sets. Then μ is σ-finite and regular, hence a Radon measure (Definition 28.3.5): for every Borel set E,*

$$\mu(E) = \inf\{\mu(U) : U \supseteq E \text{ open}\} = \sup\{\mu(K) : K \subseteq E \text{ compact}\}.$$

Proof. X is the union of the compact sets K_m of an exhaustion, which have finite measure, so μ is σ-finite; and every point has a neighbourhood $\operatorname{int} K_{m+1} \subseteq K_{m+1}$ of finite measure. The measures $\nu_m(A) = \mu(A \cap \operatorname{int} K_m)$ are finite, and Lemma 28.14.1 applies to them, X being metrisable.

Outer regularity. Let E be a Borel set with $\mu(E) < \infty$ (otherwise there is nothing to prove) and $\varepsilon > 0$. Choose open sets $U_m \supseteq E$ with $\nu_m(U_m \setminus E) < \varepsilon 2^{-m}$, and let $U = \bigcup_m (U_m \cap \operatorname{int} K_m)$. It is open and contains $E = \bigcup_m (E \cap \operatorname{int} K_m)$, and $\mu(U \setminus E) \le \sum_m \mu\big((U_m \cap \operatorname{int} K_m) \setminus E\big) = \sum_m \nu_m(U_m \setminus E) < \varepsilon$. So $\mu(U) < \mu(E) + \varepsilon$.

Inner regularity. Let E be a Borel set and $t < \mu(E)$. By continuity from below, $\mu(E \cap \operatorname{int} K_m) > t$ for some m. Choose a closed $F \subseteq E$ with $\nu_m(E \setminus F) < \mu(E \cap \operatorname{int} K_m) - t$. Then $K = F \cap K_m$ is compact, contained in E, and $\mu(K) \ge \mu(F \cap \operatorname{int} K_m) = \nu_m(E) - \nu_m(E \setminus F) > t$. □

So on $\mathbb{R}^n$ and on manifolds, *Radon measure* simply means *Borel measure finite on compact sets*. For general locally compact Hausdorff spaces this is false, and the theory below has to be set up with more care [Rud87, Chapter 2]; we shall not need that generality.

Lemma 28.14.3. *Let X be a locally compact Hausdorff space, $K \subseteq X$ compact and $V_1, \dots, V_n$ open sets covering K. There are $h_i \prec V_i$ with $\sum_i h_i \le 1$ on X and $\sum_i h_i = 1$ on K.*

Proof. Each $x \in K$ lies in some V_i, and Lemma 18.9.5 gives an open $W_x \ni x$ with compact closure $\overline{W_x} \subseteq V_i$. Finitely many W_x cover K; let H_i be the union of the closures of those among them for which the chosen i was i. Then $H_i \subseteq V_i$ is compact and $K \subseteq H_1 \cup \cdots \cup H_n$. Lemma 18.9.5 gives $g_i \prec V_i$ with $g_i = 1$ on H_i. Put $h_1 = g_1$ and $h_k = (1 - g_1) \cdots (1 - g_{k-1}) g_k$. Then $0 \le h_k \le g_k$, so $h_k \prec V_k$, and by induction on m,

$$h_1 + \cdots + h_m = 1 - (1 - g_1)(1 - g_2) \cdots (1 - g_m),$$

since $1 - \prod_{k \le m}(1 - g_k) + h_{m+1} = 1 - \prod_{k \le m+1}(1 - g_k)$. For $m = n$ the right side lies in $[0, 1]$, and it equals 1 on each H_i, where the factor $1 - g_i$ vanishes. □

Definition 28.14.4. A linear map $\Lambda \colon C_c(X) \to \mathbb{R}$ is *positive* if $\Lambda(f) \ge 0$ whenever $f \ge 0$.

A positive functional is monotone: $f \le g$ implies $\Lambda f \le \Lambda g$. It is also automatically continuous in the following sense. If K is compact and $\phi_K \in C_c(X)$ satisfies $0 \le \phi_K \le 1$ and $\phi_K = 1$ on K (Lemma 18.9.5), then every f with $\operatorname{supp} f \subseteq K$ satisfies $-\|f\|_\infty \phi_K \le f \le \|f\|_\infty \phi_K$, hence

$$|\Lambda f| \le \Lambda(\phi_K)\, \|f\|_\infty.$$

So uniform convergence of functions supported in a fixed compact set implies convergence of the values of Λ.

Example 28.14.5. 1. *Point masses.* $\Lambda f = f(x_0)$ is positive, and $\Lambda f = \int f\, d\delta_{x_0}$. More generally, for points $x_1, x_2, \ldots$ of X with no accumulation point and numbers $c_k \geq 0$, the finite sum $\Lambda f = \sum_k c_k f(x_k)$ is integration against $\sum_k c_k \delta_{x_k}$.

2. *Densities.* For $g \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$ with $g \geq 0$, $\Lambda f = \int f g\, d\lambda$ is positive; it is integration against the measure $g\lambda$, $E \mapsto \int_E g\, d\lambda$. For $g = 1$ this is the Riemann integral of f (Proposition 28.4.9, together with Fubini's theorem for the iterated integrals).

3. *Arc length on a circle.* On $X = \mathbb{R}^2$, $\Lambda f = \int_0^{2\pi} f(\cos t, \sin t)\, dt$ is positive. The corresponding measure σ (Theorem 28.14.6 below) lives on the unit circle S^1: if K is compact and disjoint from S^1, a function $f \prec \mathbb{R}^2 \setminus S^1$ with $f = 1$ on K gives $\sigma(K) \leq \int f\, d\sigma = \Lambda f = 0$, and by inner regularity $\sigma(\mathbb{R}^2 \setminus S^1) = 0$. Since $\lambda^2(S^1) = 0$, the measures σ and λ^2 are mutually singular. The measure of an arc is its length (Exercise 28.23.13), and σ is the restriction to S^1 of the one-dimensional Hausdorff measure of Section 28.17.

4. *Push-forward.* More generally, for a continuous map $\varphi\colon [a,b] \to X$, the functional $\Lambda f = \int_a^b f(\varphi(t))\, dt$ is integration against the push-forward $\varphi_*\lambda$, $E \mapsto \lambda(\{t \in [a,b] : \varphi(t) \in E\})$, which is a Borel measure, finite because $\lambda([a,b]) < \infty$.

Theorem 28.14.6 (Riesz–Markov)**.** *Let X be a locally compact Hausdorff space with a countable basis, and $\Lambda\colon C_c(X) \to \mathbb{R}$ a positive linear functional. There is a unique Borel measure μ on X, finite on compact sets, with*

$$\Lambda f = \int_X f\, d\mu \qquad \text{for all } f \in C_c(X).$$

It is a Radon measure, and for open V and compact K,

$$\mu(V) = \sup\{\Lambda f : f \prec V\}, \qquad \mu(K) = \inf\{\Lambda f : f \in C_c(X),\ f \geq \mathbf{1}_K\}.$$

Proof. The proof follows [Rud87, Theorem 2.14]. Motivated by the formulas to be proved, define $\mu(V) = \sup\{\Lambda f : f \prec V\}$ for open V, and for an arbitrary $E \subseteq X$

$$\mu^*(E) = \inf\{\mu(V) : V \supseteq E \text{ open}\}.$$

If $V \subseteq W$ are open, $f \prec V$ implies $f \prec W$, so $\mu(V) \leq \mu(W)$; hence $\mu^*(V) = \mu(V)$ for open V, and μ^* is monotone.

Step 1: μ^* is an outer measure. First let $V = \bigcup_i V_i$ be a countable union of open sets, and $f \prec V$. The compact set $\operatorname{supp} f$ is covered by finitely many $V_1, \ldots, V_n$, and Lemma 28.14.3 gives $h_i \prec V_i$ with $\sum_i h_i = 1$ on $\operatorname{supp} f$. Then $f = \sum_i h_i f$ with $h_i f \prec V_i$, so $\Lambda f = \sum_i \Lambda(h_i f) \leq \sum_i \mu(V_i)$; taking the supremum over f, $\mu(V) \leq \sum_i \mu(V_i)$. Now let $E = \bigcup_i E_i$ be arbitrary, with $\sum_i \mu^*(E_i) < \infty$, and $\varepsilon > 0$. Choose open $V_i \supseteq E_i$ with $\mu(V_i) \leq \mu^*(E_i) + \varepsilon 2^{-i}$; then $\mu^*(E) \leq \mu(\bigcup_i V_i) \leq \sum_i \mu^*(E_i) + \varepsilon$. Finally $\mu^*(\emptyset) = 0$, as $f \prec \emptyset$ forces $f = 0$.

Step 2: compact sets. Let K be compact. If $f \in C_c(X)$ and $f \geq \mathbf{1}_K$, and $0 < \alpha < 1$, then $V_\alpha = \{f > \alpha\}$ is an open set containing K, and every $g \prec V_\alpha$ satisfies $\alpha g \leq f$; so $\mu^*(K) \leq \mu(V_\alpha) \leq \Lambda f/\alpha$, and letting $\alpha \to 1$, $\mu^*(K) \leq \Lambda f$. Conversely, for an open $V \supseteq K$, Lemma 18.9.5 gives $f \prec V$ with $f = 1$ on K, and $\Lambda f \leq \mu(V)$. So $\mu^*(K) = \inf\{\Lambda f : f \geq \mathbf{1}_K\}$, which is finite.

Step 3: Borel sets are μ^*-measurable. By Carathéodory's theorem (Theorem 28.3.2) the μ^*-measurable sets form a σ-algebra on which μ^* is a measure, so it suffices to show that every open U is μ^*-measurable: $\mu^*(E \cap U) + \mu^*(E \setminus U) \leq \mu^*(E)$ for every E with $\mu^*(E) < \infty$. Let $\varepsilon > 0$ and choose an open $V \supseteq E$ with $\mu(V) \leq \mu^*(E) + \varepsilon$. Choose $f \prec V \cap U$ with $\Lambda f > \mu(V \cap U) - \varepsilon$;

its support K is a compact subset of U, so $V \setminus K$ is open and we may choose $g \prec V \setminus K$ with $\Lambda g > \mu(V \setminus K) - \varepsilon$. The functions f and g have disjoint supports, so $f + g \prec V$, and

$$\mu^*(E) + \varepsilon \geq \mu(V) \geq \Lambda f + \Lambda g > \mu(V \cap U) + \mu(V \setminus K) - 2\varepsilon \geq \mu^*(E \cap U) + \mu^*(E \setminus U) - 2\varepsilon,$$

because $E \cap U \subseteq V \cap U$ and $E \setminus U \subseteq V \setminus K$. Let $\varepsilon \to 0$.

So the restriction of μ^* to the Borel sets is a Borel measure μ, finite on compact sets by Step 2, and by construction it satisfies the two formulas of the statement.

Step 4: $\Lambda f = \int f \, d\mu$. Both sides are linear in f, so it suffices to show $\Lambda f \leq \int f \, d\mu$ for every $f \in C_c(X)$: applied to $-f$ it gives the reverse inequality. Let $K = \operatorname{supp} f$, choose $a < b$ with $f(X) \subseteq [a, b]$, let $\varepsilon > 0$, and choose $y_0 < a < y_1 < \cdots < y_n = b$ with $y_i - y_{i-1} < \varepsilon$. The Borel sets $E_i = \{y_{i-1} < f \leq y_i\} \cap K$ are disjoint with union K. By the definition of μ^* there are open sets $V_i \supseteq E_i$ with $\mu(V_i) < \mu(E_i) + \varepsilon/n$; replacing V_i by $V_i \cap \{f < y_i + \varepsilon\}$ we may assume $f < y_i + \varepsilon$ on V_i. Lemma 28.14.3 gives $h_i \prec V_i$ with $\sum_i h_i = 1$ on K. Then $f = \sum_i h_i f$, and $h_i f \leq (y_i + \varepsilon) h_i$. By Step 2, $\sum_i \Lambda h_i = \Lambda(\sum_i h_i) \geq \mu(K)$, and $\Lambda h_i \leq \mu(V_i)$. As $|a| + y_i + \varepsilon > 0$,

$$\begin{aligned}
\Lambda f = \sum_i \Lambda(h_i f) &\leq \sum_i (y_i + \varepsilon) \Lambda h_i = \sum_i (|a| + y_i + \varepsilon) \Lambda h_i - |a| \sum_i \Lambda h_i \\
&\leq \sum_i (|a| + y_i + \varepsilon) \Big(\mu(E_i) + \frac{\varepsilon}{n} \Big) - |a| \mu(K) \\
&\leq \sum_i (y_i - \varepsilon) \mu(E_i) + 2\varepsilon \mu(K) + \varepsilon(|a| + b + \varepsilon),
\end{aligned}$$

using $\sum_i \mu(E_i) = \mu(K)$ and $y_i \leq b$. On E_i we have $f > y_{i-1} > y_i - \varepsilon$, so $\sum_i (y_i - \varepsilon) \mu(E_i) \leq \int f \, d\mu$. Letting $\varepsilon \to 0$ gives $\Lambda f \leq \int f \, d\mu$.

Step 5: regularity and uniqueness. μ is a Radon measure by Proposition 28.14.2. Let μ' be another Borel measure, finite on compact sets, representing Λ, and K compact. If $f \geq \mathbf{1}_K$, then $\mu'(K) \leq \int f \, d\mu' = \Lambda f$, so $\mu'(K) \leq \mu(K)$ by Step 2. If $V \supseteq K$ is open and $f \prec V$ with $f = 1$ on K, then $\mu(K) \leq \Lambda f = \int f \, d\mu' \leq \mu'(V)$, and by outer regularity of μ' (Proposition 28.14.2) $\mu(K) \leq \mu'(K)$. So μ and μ' agree on compact sets, hence, by inner regularity, on all Borel sets. □

Remark 28.14.7.

1. For $X = \mathbb{R}^n$ and Λ the Riemann integral, the theorem produces Lebesgue measure on the Borel sets; the uniqueness statement is a convenient way to identify measures, as in Exercise 28.23.13. On a smooth manifold, an orientation and a volume form, or more generally a density, define a positive functional by integration, and hence a Radon measure (Chapter 36).

2. The theorem holds for every locally compact Hausdorff space, but then the measure is only outer regular and inner regular on open sets and on sets of finite measure [Rud87, Theorem 2.14 and Theorem 2.18].

3. If X is compact, $1 \in C_c(X)$, and $|\Lambda f| \leq \Lambda(1) \|f\|_\infty = \mu(X) \|f\|_\infty$: a positive functional on $C(X)$ is bounded with norm $\mu(X)$. Every bounded linear functional on $C(X)$ is integration against a *signed* Radon measure, a difference of two finite Radon measures [Rud87, Theorem 6.19] (for the spaces of this section, see Corollary 28.14.10 below); this identifies the dual space of $C(X)$, a theme of Chapter 30.

28.14.1 Signed and vector-valued functionals

Many natural linear functionals are not positive. The functional $\varphi \mapsto \varphi(0) - \varphi(1)$ on $C_c(\mathbb{R})$ is the difference of two Dirac measures; $\varphi \mapsto \int \varphi h \, d\lambda$ with h changing sign is the

difference of the measures $h^+\lambda$ and $h^-\lambda$. In geometric measure theory one also meets functionals on *vector fields*: for the unit circle $S^1 \subseteq \mathbb{R}^2$ with outward normal $n(x) = x$, the *flux* $F \mapsto \int_0^{2\pi} \langle F(\cos t, \sin t), (\cos t, \sin t)\rangle\, dt$ through the circle is a linear functional on continuous vector fields $F\colon \mathbb{R}^2 \to \mathbb{R}^2$ with compact support. The Riesz representation theorem extends to all these cases: a functional that is merely bounded on functions of bounded size supported in a fixed compact set is integration against a measure, after pairing with a field of unit vectors.

Let H be a finite-dimensional real vector space with an inner product $\langle\,,\rangle$ and norm $|\,|$; for instance $H = \mathbb{R}^m$ with the standard inner product. Let $C_c(X, H)$ be the vector space of continuous maps $f\colon X \to H$ with compact support. For $f \in C_c(X, H)$ the function $|f|$ belongs to $C_c(X)$. The map $r\colon H \to H$, $r(v) = v$ for $|v| \le 1$ and $r(v) = v/|v|$ for $|v| > 1$, the nearest point projection onto the closed unit ball, is continuous, takes values in the ball, and moves no point farther from the ball: $|r(u) - w| \le |u - w|$ whenever $|w| \le 1$. To see this, we may assume $|u| > 1$; then $|u - w|^2 - |r(u) - w|^2 = |u|^2 - 1 - 2(|u| - 1)\langle u/|u|, w\rangle \ge |u|^2 - 1 - 2(|u| - 1) = (|u| - 1)^2 \ge 0$.

Lemma 28.14.8. *Let μ be a Radon measure on X.*

1. *For $1 \le p < \infty$, $C_c(X)$ is dense in $L^p(\mu)$.*

2. *Let $w\colon X \to H$ be Borel with $|w| \le 1$, E a Borel set with $\mu(E) < \infty$, and $V \supseteq E$ open. For every $\varepsilon > 0$ there is $g \in C_c(X, H)$ with $|g| \le 1$, $\operatorname{supp} g \subseteq V$ and $\int |g - \mathbf{1}_E w|\, d\mu < \varepsilon$.*

Proof. (1) As in Proposition 28.5.4, simple functions $\sum a_i \mathbf{1}_{E_i}$ with $\mu(E_i) < \infty$ are dense in $L^p(\mu)$, by Proposition 28.2.6(4) and dominated convergence. Given E with $\mu(E) < \infty$ and $\varepsilon > 0$, regularity of μ gives a compact K and an open U with $K \subseteq E \subseteq U$ and $\mu(U \setminus K) < \varepsilon$, and Lemma 18.9.5 gives $\phi \in C_c(X)$ with $0 \le \phi \le 1$, $\phi = 1$ on K and $\operatorname{supp}\phi \subseteq U$. Then $\int |\mathbf{1}_E - \phi|^p\, d\mu \le \mu(U \setminus K) < \varepsilon$.

(2) Fix an orthonormal basis $e_1, \dots, e_m$ of H and write $w = \sum_j w_j e_j$. By (1) choose $\phi_j \in C_c(X)$ with $\int |\phi_j - \mathbf{1}_E w_j|\, d\mu < \varepsilon/(2m)$, and put $g_0 = \sum_j \phi_j e_j$, so $\int |g_0 - \mathbf{1}_E w|\, d\mu < \varepsilon/2$. Then $g_1 = r \circ g_0$ is continuous with compact support, $|g_1| \le 1$, and $|g_1 - \mathbf{1}_E w| \le |g_0 - \mathbf{1}_E w|$ pointwise, as $|\mathbf{1}_E w| \le 1$. Choose a compact $K \subseteq E$ with $\mu(E \setminus K) < \varepsilon/4$ and $\psi \in C_c(X)$ with $0 \le \psi \le 1$, $\psi = 1$ on K and $\operatorname{supp}\psi \subseteq V$, and let $g = \psi g_1$. On K, $g = g_1$; outside E, $|g - \mathbf{1}_E w| = |g| \le |g_1| = |g_1 - \mathbf{1}_E w|$; on $E \setminus K$, $|g - w| \le 2$. Hence $\int |g - \mathbf{1}_E w|\, d\mu \le \int |g_1 - \mathbf{1}_E w|\, d\mu + 2\mu(E \setminus K) < \varepsilon$. □

Theorem 28.14.9 (Riesz representation theorem for vector-valued functions)**.** *Let $L\colon C_c(X, H) \to \mathbb{R}$ be linear and suppose that for every compact $K \subseteq X$*

$$M_K = \sup\bigl\{L(f) : f \in C_c(X, H),\ |f| \le 1,\ \operatorname{supp} f \subseteq K\bigr\} < \infty.$$

Then there are a Radon measure μ on X and a Borel map $v\colon X \to H$ with $|v| = 1$ μ-almost everywhere such that

$$L(f) = \int_X \langle f, v\rangle\, d\mu \qquad \text{for all } f \in C_c(X, H).$$

Moreover, for every open $V \subseteq X$,

$$\mu(V) = \sup\bigl\{L(f) : f \in C_c(X, H),\ |f| \le 1,\ \operatorname{supp} f \subseteq V\bigr\}, \tag{28.1}$$

and the pair (μ, v) is unique: μ is unique, and v is unique up to μ-null sets. The measure μ is the total variation measure *of L.*

Proof. The idea is to manufacture a positive functional out of L, namely the largest value of L on fields dominated by a given function, and to apply the Riesz–Markov theorem to it.

Step 1: a positive functional on nonnegative functions. For $\varphi \in C_c(X)$ with $\varphi \geq 0$ let

$$\lambda(\varphi) = \sup\bigl\{L(g) : g \in C_c(X,H),\ |g| \leq \varphi\bigr\}.$$

Taking $g = 0$ shows $\lambda(\varphi) \geq 0$. If $|g| \leq \varphi$, then $\operatorname{supp} g \subseteq K = \operatorname{supp}\varphi$, and if $\varphi \neq 0$, $g/\|\varphi\|_\infty$ is admissible in the definition of M_K; so $L(g) \leq \|\varphi\|_\infty M_K$ and $\lambda(\varphi) < \infty$. Clearly $\lambda(c\varphi) = c\lambda(\varphi)$ for $c > 0$, as $g \mapsto cg$ matches the admissible fields. We show $\lambda(\varphi_1+\varphi_2) = \lambda(\varphi_1)+\lambda(\varphi_2)$ for $\varphi_1, \varphi_2 \geq 0$. If $|g_i| \leq \varphi_i$, then $|g_1+g_2| \leq \varphi_1+\varphi_2$, so $L(g_1)+L(g_2) \leq \lambda(\varphi_1+\varphi_2)$; taking suprema gives "$\geq$". Conversely let $|g| \leq \varphi_1+\varphi_2$, and define $g_i = \varphi_i g/(\varphi_1+\varphi_2)$ where $\varphi_1+\varphi_2 > 0$ and $g_i = 0$ elsewhere. Then $|g_i| \leq \varphi_i$, and g_i is continuous: this is clear where $\varphi_1+\varphi_2 > 0$, and at a point x_0 where $\varphi_1+\varphi_2 = 0$ we have $|g_i| \leq \varphi_i$ everywhere and $\varphi_i(x_0) = 0$, so $g_i(x) \to 0 = g_i(x_0)$ as $x \to x_0$. Since $g = 0$ where $\varphi_1+\varphi_2 = 0$, $g = g_1+g_2$, and $L(g) = L(g_1)+L(g_2) \leq \lambda(\varphi_1)+\lambda(\varphi_2)$.

Step 2: extension and the measure μ. For $\varphi \in C_c(X)$ put $\lambda(\varphi) = \lambda(\varphi^+) - \lambda(\varphi^-)$, where $\varphi^\pm = \max(\pm\varphi, 0) \in C_c(X)$. If $\varphi = a - b$ with $a, b \geq 0$ in $C_c(X)$, then $\varphi^+ + b = \varphi^- + a$, and Step 1 gives $\lambda(\varphi) = \lambda(a) - \lambda(b)$. Writing $\varphi+\psi = (\varphi^+ + \psi^+) - (\varphi^- + \psi^-)$ shows that λ is additive; it is homogeneous for $c \geq 0$ by Step 1, and $\lambda(-\varphi) = -\lambda(\varphi)$ since $(-\varphi)^\pm = \varphi^\mp$. So λ is a positive linear functional on $C_c(X)$, and the Riesz–Markov theorem (Theorem 28.14.6) gives a Radon measure μ with $\lambda(\varphi) = \int \varphi\, d\mu$.

Step 3: $|L(g)| \leq \int |g|\, d\mu$. For $g \in C_c(X,H)$, g is admissible for $\lambda(|g|)$, so $L(g) \leq \lambda(|g|) = \int |g|\, d\mu$; apply this also to $-g$.

Step 4: construction of ν. Fix an orthonormal basis $e_1, \dots, e_m$ of H and let $L_j(\varphi) = L(\varphi e_j)$ for $\varphi \in C_c(X)$. By Step 3, $|L_j(\varphi)| \leq \int |\varphi|\, d\mu$, so $\Lambda_j(\varphi) = \int \varphi\, d\mu + L_j(\varphi)$ is a positive linear functional on $C_c(X)$. By the Riesz–Markov theorem there is a Radon measure σ_j with $\Lambda_j(\varphi) = \int \varphi\, d\sigma_j$. For open V and $\varphi \prec V$, $\Lambda_j(\varphi) \leq 2\int \varphi\, d\mu \leq 2\mu(V)$, so $\sigma_j(V) \leq 2\mu(V)$ by the formula for $\sigma_j(V)$ in Theorem 28.14.6; by outer regularity of μ, $\sigma_j(E) \leq 2\mu(E)$ for all Borel E. Both measures are σ-finite (Proposition 28.14.2) and $\sigma_j \ll \mu$, so by the Radon–Nikodym theorem (Theorem 28.12.2) $\sigma_j(E) = \int_E h_j\, d\mu$ for a Borel function $h_j \geq 0$. Since $\int_E h_j\, d\mu \leq 2\mu(E)$ for all E, applied to $E = \{h_j > 2\} \cap K_m$ for the compact exhaustion (K_m), $h_j \leq 2$ almost everywhere, and we may change h_j on a null set so that $0 \leq h_j \leq 2$ everywhere. By the usual extension from indicator functions to simple functions and limits, $\int \varphi\, d\sigma_j = \int \varphi h_j\, d\mu$ for $\varphi \in C_c(X)$. Put $v_j = h_j - 1 \in [-1,1]$ and $\nu = \sum_j v_j e_j$, a Borel map with $|\nu| \leq \sqrt{m}$. Then $L_j(\varphi) = \int \varphi\, v_j\, d\mu$, and for $f \in C_c(X,H)$, writing $f = \sum_j \langle f, e_j\rangle e_j$ with $\langle f, e_j\rangle \in C_c(X)$,

$$L(f) = \sum_j L_j\bigl(\langle f, e_j\rangle\bigr) = \int \sum_j \langle f, e_j\rangle v_j\, d\mu = \int \langle f, \nu\rangle\, d\mu.$$

Step 5: $|\nu| \leq 1$ almost everywhere. Let $E = \{|\nu| > 1\} \cap K_m$ and $w = \nu/|\nu|$ on E, $w = 0$ elsewhere. For $\varepsilon > 0$, Lemma 28.14.8(2) gives $g \in C_c(X,H)$ with $|g| \leq 1$ and $\int |g - \mathbf{1}_E w|\, d\mu < \varepsilon$. Then, by Step 3,

$$\int_E |\nu|\, d\mu = \int \langle \mathbf{1}_E w, \nu\rangle\, d\mu \leq L(g) + \sqrt{m}\,\varepsilon \leq \int |g|\, d\mu + \sqrt{m}\,\varepsilon \leq \mu(E) + (1+\sqrt{m})\varepsilon.$$

So $\int_E (|\nu| - 1)\, d\mu \leq 0$, while $|\nu| - 1 > 0$ on E; hence $\mu(E) = 0$, for every m.

Step 6: $|\nu| \geq 1$ almost everywhere. For $\varphi \geq 0$ in $C_c(X)$ and $|g| \leq \varphi$, $L(g) = \int \langle g, \nu\rangle\, d\mu \leq \int \varphi|\nu|\, d\mu$; taking the supremum, $\int \varphi\, d\mu = \lambda(\varphi) \leq \int \varphi|\nu|\, d\mu$, that is, $\int \varphi(1 - |\nu|)\, d\mu \leq 0$. Given a compact K, choose such φ with $\varphi = 1$ on K and $0 \leq \varphi \leq 1$ (Lemma 18.9.5); as $1 - |\nu| \geq 0$

almost everywhere by Step 5, $\int_K (1-|\nu|)\,d\mu \le \int \varphi(1-|\nu|)\,d\mu \le 0$, so $|\nu| = 1$ almost everywhere on K, and on $X = \bigcup_m K_m$.

Step 7: the formula (28.1) *and uniqueness.* Let (μ', ν') be any pair with the properties of the theorem; we show that $\mu'(V)$ equals the right side $s(V)$ of (28.1). If $|f| \le 1$, then $L(f) = \int \langle f, \nu' \rangle\, d\mu' \le \int_V |f|\, d\mu' \le \mu'(V)$ for $\operatorname{supp} f \subseteq V$, so $s(V) \le \mu'(V)$. Conversely, let $K \subseteq V$ be compact and $\varepsilon > 0$. Lemma 28.14.8(2), applied to μ', $w = \nu'$ and $E = K$, gives g with $|g| \le 1$, $\operatorname{supp} g \subseteq V$ and $\int |g - \mathbf{1}_K \nu'|\, d\mu' < \varepsilon$, so $L(g) \ge \int_K |\nu'|^2\, d\mu' - \varepsilon = \mu'(K) - \varepsilon$. By inner regularity $s(V) \ge \mu'(V)$. Hence $\mu'(V) = s(V)$ for all open V; this proves (28.1) for μ, and shows that μ' and μ agree on open sets, hence on all Borel sets by outer regularity. Finally $\int \langle f, \nu - \nu' \rangle\, d\mu = 0$ for all $f \in C_c(X, H)$. Let $E = \{\nu \ne \nu'\} \cap K_m$ and $w = (\nu - \nu')/|\nu - \nu'|$ on E, 0 elsewhere; approximating $\mathbf{1}_E w$ by g as in Lemma 28.14.8(2) and using $|\nu - \nu'| \le 2$ almost everywhere gives $\int_E |\nu - \nu'|\, d\mu \le 2\varepsilon$ for every ε, so $\nu = \nu'$ almost everywhere on E, and on X. □

For a positive functional on $C_c(X) = C_c(X, \mathbb{R})$ the theorem gives back the Riesz–Markov measure with $\nu = 1$. For general functionals on $C_c(X)$ it gives the decomposition into a positive and a negative part.

Corollary 28.14.10. *Let $L\colon C_c(X) \to \mathbb{R}$ be linear with $\sup\{|L(\varphi)| : |\varphi| \le 1, \operatorname{supp}\varphi \subseteq K\} < \infty$ for every compact K. Then there are Radon measures μ^+ and μ^-, concentrated on disjoint Borel sets X^+ and X^-, with*

$$L(\varphi) = \int \varphi\, d\mu^+ - \int \varphi\, d\mu^- \qquad (\varphi \in C_c(X)).$$

If X is compact, every bounded linear functional L on $C(X)$ (with the norm $\|\ \|_\infty$) has this form with $\mu^\pm$ finite, and

$$\|L\| = \|\mu^+ - \mu^-\| = \mu^+(X) + \mu^-(X),$$

the total variation norm *of the signed measure $\mu^+ - \mu^-$, $E \mapsto \mu^+(E) - \mu^-(E)$: the norm of the functional is the norm of the measure.*

Proof. Apply Theorem 28.14.9 with $H = \mathbb{R}$. Then $\nu = \pm 1$ almost everywhere; let $X^\pm = \{\nu = \pm 1\}$ and $\mu^\pm(E) = \mu(E \cap X^\pm)$, Borel measures finite on compact sets, hence Radon by Proposition 28.14.2. Then $\int \varphi\nu\, d\mu = \int \varphi\, d\mu^+ - \int \varphi\, d\mu^-$. If X is compact and L is bounded, the hypothesis holds with the constant $\|L\|$, $\mu^\pm(X) \le \mu(X) < \infty$, and (28.1) with $V = X$ gives $\mu(X) = \sup\{L(\varphi) : \|\varphi\|_\infty \le 1\} = \|L\|$. □

For a signed measure $\mu = \mu^+ - \mu^-$ as in the corollary, with $\|\mu\| = \mu^+(X) + \mu^-(X)$, the total variation norm is intrinsic to the set function μ: $\|\mu\| = \sup \sum_i |\mu(E_i)|$ over all finite partitions of X into Borel sets E_i. Indeed $\sum_i |\mu(E_i)| \le \sum_i (\mu^+(E_i) + \mu^-(E_i)) = \|\mu\|$, with equality for the partition $\{X^+, X \setminus X^+\}$. For example $\|\delta_0 - \delta_1\| = 2$, and $\|h\lambda\| = \int |h|\, d\lambda$ for the measure $E \mapsto \int_E h\, d\lambda$ with $h \in L^1$. So the dual space of $C(X)$, for a compact metrisable X, is the space of signed Radon measures with the total variation norm; this proves the statement quoted in Remark 28.14.7(3) for the spaces of this section. The decomposition $X = X^+ \cup X^-$ is the *Hahn decomposition* and $\mu^\pm$ the *Jordan decomposition* of the signed measure $\mu^+ - \mu^-$.

For a noncompact X the natural Banach space is $C_0(X)$, the space of continuous $f : X \to \mathbb{R}$ *vanishing at infinity*: for every $\varepsilon > 0$ the set $\{|f| \ge \varepsilon\}$ is compact. With the norm $\|f\|_\infty$ it is a closed subspace of the bounded continuous functions, hence complete (a uniform limit of functions vanishing at infinity vanishes at infinity), and it contains $C_c(X)$ as a dense subspace: for $f \in C_0(X)$ and $\varepsilon > 0$, Lemma 18.9.5 gives $\psi \prec X$ with $\psi = 1$ on the compact set $\{|f| \ge \varepsilon\}$, and then $\psi f \in C_c(X)$ and $\|f - \psi f\|_\infty \le \varepsilon$. For $X = \mathbb{R}^n$, $e^{-|x|^2}$ and $1/(1+|x|^2)$ lie in C_0, while the constant 1 does not. As in Corollary 28.14.10, a *finite signed Radon measure* is a difference $\mu = \mu^+ - \mu^-$ of finite Radon measures concentrated on disjoint Borel sets, with total variation norm $\|\mu\| = \mu^+(X) + \mu^-(X)$ and $\int f\, d\mu = \int f\, d\mu^+ - \int f\, d\mu^-$.

Corollary 28.14.11 (The dual of $C_0(X)$)**.** *For every bounded linear functional L on $C_0(X)$ there is a unique finite signed Radon measure μ with*

$$L(f) = \int f \, d\mu \quad (f \in C_0(X)), \qquad \|L\| = \|\mu\|.$$

Conversely every finite signed Radon measure defines in this way a bounded functional of norm $\|\mu\|$. So $C_0(X)^*$ is isometrically isomorphic to the space of finite signed Radon measures with the total variation norm. More generally, with H as above, every bounded linear functional on $C_0(X, H)$ (with the norm $\sup_x |f(x)|$) is $f \mapsto \int \langle f, \nu \rangle \, d\mu$ with μ a finite Radon measure of mass $\mu(X) = \|L\|$ and $|\nu| = 1$ μ-almost everywhere.

Proof. We prove the vector-valued statement; the scalar one is the case $H = \mathbb{R}$, with $\mu^{\pm}$ as in the proof of Corollary 28.14.10. The restriction of L to $C_c(X, H)$ satisfies the hypothesis of Theorem 28.14.9 with $M_K \le \|L\|$, which gives μ and ν. By (28.1) with $V = X$, $\mu(X) = \sup\{L(f) : f \in C_c(X, H), |f| \le 1\} \le \|L\|$; in particular μ is finite. The functional $f \mapsto \int \langle f, \nu \rangle \, d\mu$ is defined on $C_0(X, H)$, with $|\int \langle f, \nu \rangle \, d\mu| \le \|f\|_\infty \mu(X)$, and it agrees with L on $C_c(X, H)$. The density argument above, applied componentwise (or with ψf for $f \in C_0(X, H)$), shows that $C_c(X, H)$ is dense in $C_0(X, H)$; two bounded functionals agreeing on a dense subspace are equal, so $L(f) = \int \langle f, \nu \rangle \, d\mu$ on $C_0(X, H)$. This also gives $\|L\| \le \mu(X)$, so $\|L\| = \mu(X)$. Uniqueness follows from the uniqueness in Theorem 28.14.9, applied to the restriction to $C_c(X, H)$. For the converse, let $\mu = \mu^+ - \mu^-$ with $\mu^{\pm}$ concentrated on disjoint Borel sets $X^{\pm}$. The functional $L(f) = \int f \, d\mu$ satisfies $|L(f)| \le \|f\|_\infty \|\mu\|$, and it is represented as in Theorem 28.14.9 by the pair $(\mu^+ + \mu^-, \mathbf{1}_{X^+} - \mathbf{1}_{X^-})$ (a finite Borel measure, hence Radon by Proposition 28.14.2). By uniqueness and the first part, $\|L\| = (\mu^+ + \mu^-)(X) = \|\mu\|$. □

Remark 28.14.12. For a noncompact X the corollary does not extend from $C_0(X)$ to the space $C_b(X)$ of all bounded continuous functions. For $X = \mathbb{N}$ with the discrete topology, $C_0(\mathbb{N}) = c_0$ is the space of sequences tending to 0, its dual is the space of finite signed measures on $\mathbb{N}$, that is, of summable sequences ℓ^1, and $C_b(\mathbb{N}) = \ell^\infty$. A bounded linear functional L on ℓ^∞ that vanishes on c_0 and has $L(\mathbf{1}) = 1$ cannot be integration against a countably additive measure: such a measure would give mass $L(\mathbf{1}_{\{n\}}) = 0$ to each point, hence mass 0 to $\mathbb{N}$. Such functionals exist, by the Hahn–Banach theorem (Chapter 30); they correspond to finitely additive measures, or to measures on a large compactification of X. This is why the compactness of X matters in Corollary 28.14.10, and why weak convergence of measures, in the next section, is defined by testing against $C_c(X)$; testing against $C_b(X)$ is a stronger condition, which also requires that no mass escapes to infinity.

Example 28.14.13.

1. For $L(\varphi) = \varphi(0) - \varphi(1)$ on $C_c(\mathbb{R})$, $\mu = \delta_0 + \delta_1$, $\nu(0) = 1$ and $\nu(1) = -1$. Indeed, for open V, the supremum in (28.1) is the number of the points $0, 1$ lying in V, attained by functions equal to 1 near 0 and -1 near 1.

2. For $h \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$ and $L(\varphi) = \int \varphi h \, d\lambda$, $\mu = |h|\lambda$ and $\nu = h/|h|$ where $h \neq 0$ (and $\nu = 1$ elsewhere, a μ-null set). The total variation of L on V is $\int_V |h| \, d\lambda$, the L^1 norm.

3. For the flux $L(F) = \int_0^{2\pi} \langle F(\cos t, \sin t), (\cos t, \sin t) \rangle \, dt = \int \langle F, n \rangle \, d\sigma$, with σ the arc length measure of Example 28.14.5(3), $\mu = \sigma$ and $\nu = n$ on S^1: the theorem recovers the curve and its unit normal from the functional. For a C^1 field F, the divergence theorem in the plane gives $L(F) = \int_{|x|<1} \operatorname{div} F \, d\lambda^2$.

Remark 28.14.14. *Sets of finite perimeter.* Example 28.14.13(3) suggests a definition of boundary measure for arbitrary sets. For a Lebesgue measurable $E \subseteq \mathbb{R}^n$ consider $L_E(F) = \int_E \operatorname{div} F \, d\lambda^n$

for C^1 vector fields F with compact support. If $\sup\{L_E(F) : |F| \le 1, \operatorname{supp} F \subseteq K\} < \infty$ for every compact K, then L_E extends by uniform approximation to $C_c(\mathbb{R}^n, \mathbb{R}^n)$, and Theorem 28.14.9 gives a Radon measure μ_E, the *perimeter measure*, and a unit vector field ν_E with $\int_E \operatorname{div} F = \int \langle F, \nu_E \rangle \, d\mu_E$: a divergence theorem for E, valid with no regularity of ∂E assumed. For a bounded open set with smooth boundary, μ_E is the $(n-1)$-dimensional Hausdorff measure $\mathcal{H}^{n-1}$ (Section 28.17) on ∂E and ν_E is the outer normal. Such sets E are the sets of *finite perimeter* of Caccioppoli and De Giorgi, and the same construction with $\int u \operatorname{div} F$ defines functions of *bounded variation*; De Giorgi's structure theorem shows that μ_E is $\mathcal{H}^{n-1}$ restricted to a countably $(n-1)$-rectifiable "reduced boundary" [EG92, Chapter 5]. This is the setting in which the isoperimetric problem and minimal surfaces are solved in geometric measure theory.

28.15 Weak convergence of measures

Sequences of measures appear whenever something discrete approximates something continuous, or something smooth approximates something singular. Riemann sums are integrals against finitely many point masses that approximate Lebesgue measure; in probability the distributions of normalised sums of random variables approximate the Gaussian distribution; smooth bumps of total mass 1 concentrating at a point approximate the Dirac measure; and in geometric measure theory one studies limits of the area measures of a sequence of surfaces, for instance of a minimising sequence for the area. Convergence $\mu_k(A) \to \mu(A)$ for all Borel sets A is far too strong for these purposes (Example 28.15.2(1)). The useful notion tests the measures against continuous functions. As in Section 28.14, X is a locally compact Hausdorff space with a countable basis.

Definition 28.15.1. A sequence of Radon measures μ_k on X *converges weakly* to a Radon measure μ, written $\mu_k \rightharpoonup \mu$, if

$$\int_X f \, d\mu_k \to \int_X f \, d\mu \qquad \text{for every } f \in C_c(X).$$

The limit is unique, by the uniqueness in Theorem 28.14.6. In probability theory this is called *vague* convergence, and *weak* convergence of probability measures means testing against all bounded continuous functions; the two agree when no mass is lost (Exercise 28.23.14). In functional analysis it is the weak-$*$ convergence of functionals on $C_c(X)$.

Example 28.15.2.

1. *Moving point masses.* If $x_k \to x$ in X, then $\delta_{x_k} \rightharpoonup \delta_x$, since $f(x_k) \to f(x)$ for continuous f. On $\mathbb{R}$, $\delta_{1/k} \rightharpoonup \delta_0$, but $\delta_{1/k}(\{0\}) = 0$ does not converge to $\delta_0(\{0\}) = 1$, and $\delta_{1/k}((0,1)) = 1$ does not converge to $\delta_0((0,1)) = 0$. So weak convergence does not imply convergence on compact sets, nor on open sets; Proposition 28.15.3 gives the inequalities that do hold.

2. *Riemann sums.* On $\mathbb{R}$ let $\mu_k = \frac{1}{k}\sum_{j=1}^{k} \delta_{j/k}$. Then $\mu_k \rightharpoonup \mathbf{1}_{[0,1]}\lambda$. Indeed $f \in C_c(\mathbb{R})$ is uniformly continuous, being continuous with compact support; with $\omega(\delta) = \sup\{|f(s) - f(t)| : |s-t| \le \delta\}$, which tends to 0 with δ,

$$\left| \int f \, d\mu_k - \int_0^1 f \, d\lambda \right| = \left| \sum_{j=1}^{k} \int_{(j-1)/k}^{j/k} \big(f(j/k) - f(t) \big) \, dt \right| \le \omega(1/k) \to 0.$$

Each μ_k lives on a finite set, of Lebesgue measure 0, while the limit is absolutely continuous with respect to λ.

3. *Approximate identities.* Let $\phi \geq 0$ be continuous on $\mathbb{R}$ with support in $[-1,1]$ and $\int \phi \, d\lambda = 1$, and $\phi_k(x) = k\phi(kx)$. Then $\int \phi_k \, d\lambda = 1$ (Theorem 28.11.2), ϕ_k vanishes outside $[-1/k, 1/k]$, and for $f \in C_c(\mathbb{R})$

$$\left| \int f\phi_k \, d\lambda - f(0) \right| = \left| \int \big(f(x) - f(0)\big)\phi_k(x) \, dx \right| \leq \omega(1/k),$$

so $\phi_k\lambda \rightharpoonup \delta_0$: absolutely continuous measures converge to a singular one.

4. *Loss of mass.* On $\mathbb{R}$, $\delta_k \rightharpoonup 0$, since every $f \in C_c(\mathbb{R})$ vanishes at k for k large; and $\frac{1}{k}\mathbf{1}_{[0,k]}\lambda \rightharpoonup 0$, since $|\int_0^k f \, d\lambda|/k \leq \|f\|_1/k$. All these measures have total mass 1, the limit has mass 0: mass can escape to infinity, by moving away or by spreading out.

5. *Oscillation.* Let $g \geq 0$ be continuous on $\mathbb{R}$ and periodic of period 2π, with mean value $\bar{g} = \frac{1}{2\pi}\int_0^{2\pi} g \, d\lambda$. Then $g(kx)\lambda \rightharpoonup \bar{g}\lambda$; for instance $(1 + \sin kx)\lambda \rightharpoonup \lambda$, although the densities $1 + \sin kx$ do not converge pointwise (at $x = \pi/2$ they run through $2, 1, 0, 1, 2, \ldots$). To see this, let $f \in C_c(\mathbb{R})$ with support in $[a,b]$ and $\varepsilon > 0$, and choose $a = a_0 < \cdots < a_N = b$ with $|f(s) - f(a_j)| \leq \varepsilon$ for $s \in [a_{j-1}, a_j]$. An interval $[k\alpha, k\beta]$ consists of $\lfloor k(\beta - \alpha)/2\pi \rfloor$ full periods and a remainder shorter than 2π, so $\int_\alpha^\beta g(kx) \, dx = \frac{1}{k}\int_{k\alpha}^{k\beta} g(t) \, dt = (\beta - \alpha)\bar{g} + r$ with $|r| \leq 4\pi\|g\|_\infty/k$. Replacing f by $f(a_j)$ on $[a_{j-1}, a_j]$ costs at most $\varepsilon(b-a)\|g\|_\infty$ in $\int fg(kx) \, dx$ and in $\bar{g}\int f \, dx$, so

$$\left| \int f(x)g(kx) \, dx - \bar{g} \int f(x) \, dx \right| \leq 2\varepsilon(b-a)\|g\|_\infty + \frac{4\pi N \|f\|_\infty \|g\|_\infty}{k},$$

whose lim sup as $k \to \infty$ is at most $2\varepsilon(b-a)\|g\|_\infty$. Fast oscillations average out; this is the measure-theoretic content of the Riemann–Lebesgue lemma.

Proposition 28.15.3. *Let $\mu_k \rightharpoonup \mu$ be Radon measures on X.*

1. *$\mu(U) \leq \liminf_k \mu_k(U)$ for every open U.*
2. *$\mu(K) \geq \limsup_k \mu_k(K)$ for every compact K.*
3. *$\mu_k(A) \to \mu(A)$ for every Borel set A with compact closure and $\mu(\partial A) = 0$.*

Proof. (1) By inner regularity, $\mu(U)$ is the supremum of $\mu(K)$ over compact $K \subseteq U$; for such K, Lemma 18.9.5 gives $f \prec U$ with $f = 1$ on K, and $\mu(K) \leq \int f \, d\mu \leq \mu(U)$. So $\mu(U) = \sup\{\int f \, d\mu : f \prec U\}$. For $f \prec U$, $\int f \, d\mu = \lim_k \int f \, d\mu_k \leq \liminf_k \mu_k(U)$.

(2) Let $V \supseteq K$ be open. By Lemma 18.9.5 there is $f \prec V$ with $f = 1$ on K, and $\limsup_k \mu_k(K) \leq \lim_k \int f \, d\mu_k = \int f \, d\mu \leq \mu(V)$. By outer regularity, the infimum of $\mu(V)$ over such V is $\mu(K)$.

(3) The interior $\operatorname{int} A$ and the closure $\overline{A}$ differ by ∂A, so $\mu(\operatorname{int} A) = \mu(A) = \mu(\overline{A})$. By (1) and (2), $\mu(A) = \mu(\operatorname{int} A) \leq \liminf_k \mu_k(\operatorname{int} A) \leq \liminf_k \mu_k(A) \leq \limsup_k \mu_k(A) \leq \limsup_k \mu_k(\overline{A}) \leq \mu(\overline{A}) = \mu(A)$. □

In Example 28.15.2(1) the inequalities are strict: $\delta_0((0,1)) = 0 < 1$ and $\delta_0(\{0\}) = 1 > 0$; the sets $(0,1)$ and $\{0\}$ have the point 0, of δ_0-measure 1, in their boundary. In (2) of the same example, (3) says that the proportion of the points j/k lying in an interval $[\alpha, \beta] \subseteq [0,1]$ tends to $\beta - \alpha$.

The main theorem about weak convergence is a compactness theorem: bounded mass on compact sets suffices for a convergent subsequence. Its proof needs a countable supply of test functions.

Lemma 28.15.4. *Let $K_1 \subseteq K_2 \subseteq \cdots$ be an exhaustion of X by compact sets with $K_m \subseteq \operatorname{int} K_{m+1}$. There is a countable set $\mathcal{D} \subseteq C_c(X)$ such that for every m, every $f \in C_c(X)$ with $\operatorname{supp} f \subseteq K_m$ and every $\varepsilon > 0$ there is $g \in \mathcal{D}$ with $\operatorname{supp} g \subseteq K_{m+1}$ and $\|f - g\|_\infty < \varepsilon$.*

Proof. First, $C(L, \mathbb{R})$ has a countable dense subset for every compact metric space (L, d). Indeed L has a countable dense subset $\{x_1, x_2, \ldots\}$ (for each j, finitely many balls of radius $1/j$ cover L; take their centres). The functions $u_i(y) = d(x_i, y)$ separate points: if $y \neq z$ and $d(x_i, y) < d(y, z)/2$, then $d(x_i, z) > d(y, z)/2 > d(x_i, y)$. By the Stone–Weierstrass theorem (Theorem 27.15.2) the polynomials in finitely many of the u_i are dense in $C(L, \mathbb{R})$, and so are those with rational coefficients, which form a countable set, since the u_i are bounded and real coefficients can be approximated by rational ones.

Each K_{m+1} is a compact metric space, X being metrisable; let $\mathcal{D}_m \subseteq C(K_{m+1}, \mathbb{R})$ be countable and dense. By Lemma 18.9.5 choose $\chi_m \in C_c(X)$ with values in $[0, 1]$, $\chi_m = 1$ on K_m and $\operatorname{supp} \chi_m \subseteq \operatorname{int} K_{m+1}$. For $u \in \mathcal{D}_m$ the function $\chi_m u$, extended by 0 outside K_{m+1}, is continuous on X: it is continuous on the open set $\operatorname{int} K_{m+1}$ and vanishes on the open set $X \setminus \operatorname{supp} \chi_m$, and these two open sets cover X. Let $\mathcal{D}$ be the set of all these functions, for all m. Given f with support in K_m, choose $u \in \mathcal{D}_m$ with $|f - u| < \varepsilon$ on K_{m+1}; then $f = \chi_m f$, so $|f - \chi_m u| = \chi_m |f - u| < \varepsilon$ on K_{m+1}, and both functions vanish outside K_{m+1}. □

Theorem 28.15.5 (Weak compactness of Radon measures)**.** *Let (μ_k) be a sequence of Radon measures on X with $\sup_k \mu_k(K) < \infty$ for every compact $K \subseteq X$. Then a subsequence converges weakly to a Radon measure.*

Proof. Let (K_m) be an exhaustion as in Lemma 28.15.4, $C_m = \sup_k \mu_k(K_m)$, and $\mathcal{D} = \{g_1, g_2, \ldots\}$ the countable set of the lemma. For each i the sequence $\int g_i \, d\mu_k$ is bounded, by $\|g_i\|_\infty \sup_k \mu_k(\operatorname{supp} g_i)$, so it has a convergent subsequence (Theorem 27.2.12). Choose a subsequence along which $\int g_1 \, d\mu_k$ converges, a further subsequence along which $\int g_2 \, d\mu_k$ converges, and so on; the diagonal sequence, the k-th term of the k-th subsequence, is a subsequence of each of them from its i-th term on. Renaming it (μ_k), $\int g \, d\mu_k$ converges for every $g \in \mathcal{D}$.

Let $f \in C_c(X)$, with support in some K_m, and $\varepsilon > 0$. Choose $g \in \mathcal{D}$ with support in K_{m+1} and $\|f - g\|_\infty < \varepsilon$. Then

$$\left| \int f \, d\mu_k - \int f \, d\mu_l \right| \leq 2\varepsilon C_{m+1} + \left| \int g \, d\mu_k - \int g \, d\mu_l \right|,$$

so $\int f \, d\mu_k$ is a Cauchy sequence. Its limit Λf is linear and positive in f, so by Theorem 28.14.6 it is $\int f \, d\mu$ for a Radon measure μ, and $\mu_k \rightharpoonup \mu$. □

Corollary 28.15.6. *Let X be a compact metric space. Every sequence of Borel probability measures on X has a subsequence converging weakly to a Borel probability measure.*

Proof. A compact metric space is locally compact and Hausdorff, and it has a countable basis: the balls of radius $1/j$ centred at the points of finite sets of such balls covering X. Every Borel measure on X that is finite is a Radon measure (Proposition 28.14.2), and $\mu_k(X) = 1$ bounds the masses. Theorem 28.15.5 gives a weakly convergent subsequence, and its limit μ satisfies $\mu(X) = \int 1 \, d\mu = \lim \int 1 \, d\mu_k = 1$, as $1 \in C_c(X)$ for compact X. □

Remark 28.15.7. 1. The hypothesis cannot be dropped: $k\delta_0$ has no weakly convergent subsequence on $\mathbb{R}$. On non-compact spaces the limit of probability measures may have smaller mass, by Example 28.15.2(4); by Proposition 28.15.3(1) applied to $U = X$, mass can only be lost, never gained.

2. Theorem 28.15.5 is a case of the Banach–Alaoglu theorem: bounded sets of linear functionals are compact for the weak-$*$ topology (Chapter 30).

3. In the calculus of variations and in geometric measure theory this is the basic source of limits. A minimising sequence of surfaces for the area, all contained in a fixed ball, has area measures with bounded mass, and a subsequence of these converges weakly to a Radon measure; the hard part, the *regularity theory*, is to show that the limit is again the area measure of a surface, perhaps with singularities. For curves, Exercise 28.23.15 shows that length can jump in the limit.

28.16 Differentiation of measures

The Lebesgue differentiation theorem (Theorem 28.9.4) says that for $h \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$ the averages $\frac{1}{\lambda(B(x,r))}\int_{B(x,r)} h$ tend to $h(x)$ for almost every x. In terms of the measure $\nu = h\lambda$ it says that $\nu(B(x,r))/\lambda(B(x,r)) \to h(x)$: the density of ν can be computed by shrinking balls. We now do this for an arbitrary Radon measure ν on $\mathbb{R}^n$. It has a Lebesgue decomposition $\nu = h\lambda + \nu_s$ with respect to λ (Theorem 28.12.3, which applies since ν is σ-finite by Proposition 28.14.2), and the shrinking balls recover h and do not see the singular part, except on a null set. In this section λ denotes Lebesgue measure on the Borel sets of $\mathbb{R}^n$.

Definition 28.16.1. Let ν be a Radon measure on $\mathbb{R}^n$. The *upper* and *lower derivatives* of ν with respect to λ at x are

$$\overline{D}\nu(x) = \limsup_{r\to 0} \frac{\nu(B(x,r))}{\lambda(B(x,r))}, \qquad \underline{D}\nu(x) = \liminf_{r\to 0} \frac{\nu(B(x,r))}{\lambda(B(x,r))},$$

in $[0,\infty]$. If they agree, their common value is the *derivative* $D\nu(x)$.

Example 28.16.2. For $\nu = \delta_0$ on $\mathbb{R}^n$, $\nu(B(x,r)) = 0$ for $r \le \|x\|$, so $D\nu(x) = 0$ for $x \neq 0$, while $D\nu(0) = \lim_r 1/\lambda(B(0,r)) = \infty$. For the measure σ on the circle (Example 28.14.5(3)), $D\sigma = 0$ outside S^1, because the balls around a point at positive distance from S^1 eventually miss S^1; at a point of S^1 the ball $B(x,r)$ meets S^1 in an arc of length about $2r$, so $\sigma(B(x,r))/\pi r^2$ behaves like $2/(\pi r)$ and $D\sigma = \infty$. In both cases the derivative is 0 almost everywhere, in accordance with the singularity of these measures.

Theorem 28.16.3 (Differentiation of measures)**.** *Let ν be a Radon measure on $\mathbb{R}^n$, and $\nu = h\lambda + \nu_s$ its Lebesgue decomposition, with $h \ge 0$ Borel and $\nu_s \perp \lambda$. Then $h \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$, and for λ-almost every x*

$$\lim_{r\to 0} \frac{1}{\lambda(B(x,r))}\Big(\int_{B(x,r)} |h(y) - h(x)|\, d\lambda(y) + \nu_s(B(x,r))\Big) = 0.$$

In particular $D\nu = h$ almost everywhere, and $\nu \perp \lambda$ if and only if $D\nu = 0$ almost everywhere.

Proof. For compact K, $\int_K h\, d\lambda \le \nu(K) < \infty$, so $h \in L^1_{\mathrm{loc}}$, and by the Lebesgue differentiation theorem (Theorem 28.9.4) the first term tends to 0 almost everywhere. It remains to show that $\overline{D}\nu_s = 0$ almost everywhere. Let S be a Borel set with $\lambda(S) = 0$ and $\nu_s(\mathbb{R}^n \setminus S) = 0$. The measure ν_s is a Borel measure finite on compact sets ($\nu_s \le \nu$), so it is a Radon measure (Proposition 28.14.2). Fix $t > 0$ and $R > 0$, and let

$$A = \{x \in B(0,R) \setminus S : \overline{D}\nu_s(x) > t\}.$$

We show $\lambda^*(A) = 0$. Let $\varepsilon > 0$. The Borel set $B(0,R) \setminus S$ has ν_s-measure 0, so by outer regularity it is contained in an open set U with $\nu_s(U) < \varepsilon$. Let G be the union of all open

balls B with $B \subseteq U$ and $\nu_s(B) > t\lambda(B)$. It is open and contains A: for $x \in A$ we have $x \in U$, so $B(x,r) \subseteq U$ for all small r, and $\nu_s(B(x,r)) > t\lambda(B(x,r))$ for some of these r. Let $K \subseteq G$ be compact. Finitely many of these balls cover K, and by the Vitali covering lemma (Lemma 28.9.1) they contain pairwise disjoint balls $B_1, \dots, B_k$ with

$$\lambda(K) \le 3^n \sum_j \lambda(B_j) < \frac{3^n}{t} \sum_j \nu_s(B_j) \le \frac{3^n}{t} \nu_s(U) < \frac{3^n \varepsilon}{t}.$$

By inner regularity of λ, $\lambda^*(A) \le \lambda(G) \le 3^n \varepsilon / t$, and as ε is arbitrary, A is a null set. Taking the union over $t = 1/j$ and $R = j$, $j \ge 1$, and adding the null set S, we find that $\overline{D}\nu_s = 0$ outside a null set.

Finally, $\nu(B(x,r))/\lambda(B(x,r))$ differs from the average of h over $B(x,r)$ by $\nu_s(B(x,r))/\lambda(B(x,r))$, and the average differs from $h(x)$ by at most the average of $|h - h(x)|$; so $D\nu = h$ almost everywhere. If $\nu \perp \lambda$, then $h = 0$ almost everywhere by uniqueness of the decomposition, so $D\nu = 0$ almost everywhere; conversely, if $D\nu = 0$ almost everywhere, then $h = 0$ almost everywhere and $\nu = \nu_s$. □

So the Radon–Nikodym derivative of the absolutely continuous part, an object obtained in Theorem 28.12.2 by an abstract Hilbert space argument, can be computed as a limit of ratios. Balls are not essential: any sets that shrink to x and occupy a fixed proportion of a ball around x will do.

Corollary 28.16.4. *Let $\nu = h\lambda + \nu_s$ be as in Theorem 28.16.3 and $c > 0$. For almost every x the following holds: if E_k are Borel sets with $E_k \subseteq B(x, r_k)$, $r_k \to 0$ and $\lambda(E_k) \ge c\lambda(B(x,r_k))$, then $\nu(E_k)/\lambda(E_k) \to h(x)$.*

Proof. Take x as in the theorem. Then

$$\left|\frac{\nu(E_k)}{\lambda(E_k)} - h(x)\right| \le \frac{1}{\lambda(E_k)} \Big(\int_{E_k} |h - h(x)|\, d\lambda + \nu_s(E_k) \Big) \le \frac{1}{c\lambda(B(x,r_k))} \Big(\int_{B(x,r_k)} |h - h(x)|\, d\lambda + \nu_s(B(x,r_k)) \Big),$$

which tends to 0. □

Corollary 28.16.5 (Lebesgue's theorem on monotone functions)**.** *Let $F\colon [a,b] \to \mathbb{R}$ be continuous and nondecreasing. Then F is differentiable almost everywhere, $F' \ge 0$ is integrable, and*

$$\int_a^b F'\, d\lambda \le F(b) - F(a),$$

with equality if and only if F is absolutely continuous.

Proof. Let μ_F be the measure of Lemma 28.13.3, and $\nu(E) = \mu_F(E \cap [a,b])$ for Borel $E \subseteq \mathbb{R}$; it is a finite Borel measure on $\mathbb{R}$, hence a Radon measure. Let $\nu = h\lambda + \nu_s$ be its Lebesgue decomposition, and let $x \in (a,b)$ be a point where Corollary 28.16.4 holds with $c = 1/4$. For $0 < r < \min(b - x, x - a)$, the intervals $(x, x + r]$ and $(x - r, x]$ have length $r = \frac{1}{4}\lambda(B(x,2r))$ and lie in $B(x,2r)$, and $\nu((x, x+r]) = F(x+r) - F(x)$, $\nu((x-r, x]) = F(x) - F(x-r)$. So both one-sided difference quotients of F at x tend to $h(x)$, and $F'(x) = h(x)$. Hence $F' = h$ almost everywhere on $[a,b]$, and

$$\int_a^b F'\, d\lambda = \int_{[a,b]} h\, d\lambda \le \nu([a,b]) = F(b) - F(a),$$

with equality if and only if $\nu_s([a,b]) = 0$, that is, $\nu_s = 0$. In that case $F(x) - F(a) = \nu([a,x]) = \int_a^x h\, d\lambda$ for all x, so F is absolutely continuous by Theorem 28.13.4. Conversely, if F is absolutely continuous, the same theorem gives $F(b) - F(a) = \int_a^b F'$. □

For the Cantor function (Counterexample 28.9.7) the inequality is strict: μ_F is singular, so $F' = 0$ almost everywhere, as we saw directly, while $F(1) - F(0) = 1$. The corollary holds for all nondecreasing functions, continuous or not: a nondecreasing function has at most countably many jumps, and the jumps contribute a further singular part to its measure [Rud87, Chapter 7]. Since a function of bounded variation is a difference of two nondecreasing functions, it is differentiable almost everywhere as well.

Remark 28.16.6. The proof used Lebesgue measure through the Vitali covering lemma, that is, through the fact that $\lambda(3B) = 3^n\lambda(B)$. To differentiate a Radon measure ν with respect to an arbitrary Radon measure μ on $\mathbb{R}^n$, which may give very different masses to B and $3B$, one uses instead the *Besicovitch covering theorem*: from every family of balls whose centres form a bounded set A one can extract a subfamily covering A that splits into a number of disjoint subfamilies depending only on n. With it one shows that $\nu(B(x,r))/\mu(B(x,r))$ converges μ-almost everywhere to the density of the part of ν absolutely continuous with respect to μ, and tends to ∞ almost everywhere for the singular part [EG92, Chapter 1]. This is the setting of geometric measure theory, where μ is often a Hausdorff measure restricted to a set.

28.17 Hausdorff measures

Lebesgue measure λ^n measures n-dimensional volume in $\mathbb{R}^n$, but it does not see lower-dimensional sets: a curve in the plane, or a surface in space, has measure 0. How long is a curve, and what is the area of a surface, without choosing a parametrisation? And how big is the Cantor set, which has measure 0 and is uncountable? Hausdorff measures answer these questions at once: for every $s \geq 0$ there is an s-dimensional measure $\mathcal{H}^s$ on any metric space, defined by covering a set with small sets C and adding up $(\operatorname{diam} C)^s$. This and the following sections are an introduction to *geometric measure theory*: Hausdorff measure and dimension, self-similar sets, differentiability of Lipschitz maps, the area formula, which computes $\mathcal{H}^k$ of parametrised k-dimensional sets, the coarea formula, which slices sets by level sets, and densities and rectifiable sets. We follow [EG92, Chapters 2–3]; the comprehensive reference is [Fed69].

Throughout, X is a metric space, $\operatorname{diam} C = \sup\{d(x,y) : x,y \in C\}$ for $C \neq \emptyset$, and $\operatorname{diam}\emptyset = 0$. For $s \geq 0$ let $\alpha(s) = \pi^{s/2}/(2^s\Gamma(\frac{s}{2}+1))$, with Γ as in Exercise 28.23.7; for an integer n, $\alpha(n)$ is the volume of a ball of diameter 1 in $\mathbb{R}^n$. The constant only serves to make $\mathcal{H}^n$ equal to Lebesgue measure on $\mathbb{R}^n$ (Theorem 28.17.5); in the sums below the empty set contributes 0 and every nonempty set C contributes $\alpha(s)(\operatorname{diam} C)^s$, with the convention $(\operatorname{diam} C)^0 = 1$, also when C is a single point.

Definition 28.17.1. For $A \subseteq X$, $s \geq 0$ and $\delta > 0$ let

$$\mathcal{H}^s_\delta(A) = \inf\Big\{\sum_k \alpha(s)(\operatorname{diam} C_k)^s : A \subseteq \bigcup_k C_k,\ \operatorname{diam} C_k \leq \delta\Big\},$$

the infimum over countable covers by sets of diameter at most δ. As δ decreases, fewer covers are allowed and $\mathcal{H}^s_\delta(A)$ increases; the *s-dimensional Hausdorff (outer) measure* is $\mathcal{H}^s(A) = \lim_{\delta\to 0}\mathcal{H}^s_\delta(A) = \sup_{\delta>0}\mathcal{H}^s_\delta(A)$.

The restriction $\operatorname{diam} C_k \leq \delta$ is essential: with arbitrary covers, a long segment could be covered by a single set and would get the same size as a short one, while small sets are forced to follow the shape of A. Replacing each C_k by its closure does not change its diameter, so closed covers give the same infimum. And $\mathcal{H}^s(A)$ only depends on the metric space A: a cover of A by subsets of X gives the cover by the sets $C_k \cap A$, of smaller diameters. In particular an isometry $A \to B$ between subsets of two metric spaces preserves $\mathcal{H}^s$.

Lemma 28.17.2 (Carathéodory's criterion)**.** *Let μ^* be an outer measure on X which is* metric*: $\mu^*(A \cup B) = \mu^*(A) + \mu^*(B)$ whenever $d(A,B) = \inf\{d(a,b) : a \in A, b \in B\} > 0$. Then every Borel set is μ^*-measurable.*

Proof. The measurable sets form a σ-algebra (Theorem 28.3.2), so it suffices to show that a closed set F is measurable, that is, $\mu^*(E \cap F) + \mu^*(E \setminus F) \le \mu^*(E)$ for every E with $\mu^*(E) < \infty$. Let $E_j = \{x \in E : d(x,F) \ge 1/j\}$. Since $d(E \cap F, E_j) \ge 1/j$, $\mu^*(E \cap F) + \mu^*(E_j) = \mu^*((E \cap F) \cup E_j) \le \mu^*(E)$, and it remains to show $\mu^*(E_j) \to \mu^*(E \setminus F)$. Let $R_j = \{x \in E : \frac{1}{j+1} \le d(x,F) < \frac{1}{j}\}$. As F is closed, $E \setminus F = E_j \cup \bigcup_{i \ge j} R_i$. If $i \ge l+2$, then $d(R_i, R_l) > 0$, so by induction $\sum_{i \le N} \mu^*(R_{2i}) = \mu^*(\bigcup_{i \le N} R_{2i}) \le \mu^*(E)$, and similarly for the odd indices. Hence $\sum_i \mu^*(R_i) < \infty$, and $\mu^*(E \setminus F) \le \mu^*(E_j) + \sum_{i \ge j} \mu^*(R_i)$, where the tail tends to 0. With $\mu^*(E_j) \le \mu^*(E \setminus F)$ this gives the limit. □

This is *Carathéodory's criterion*; it is a different statement from Carathéodory's theorem (Theorem 28.3.2), which it uses: the theorem builds a measure from any outer measure, and the criterion says that for a metric outer measure the resulting σ-algebra contains the Borel sets.

Proposition 28.17.3.

1. *$\mathcal{H}^s$ is a metric outer measure, so its restriction to the Borel sets is a measure.*
2. *$\mathcal{H}^0$ is the counting measure.*
3. *If $f : A \to Y$ is Lipschitz with constant L, then $\mathcal{H}^s(f(A)) \le L^s \mathcal{H}^s(A)$. For $X = \mathbb{R}^n$, $\mathcal{H}^s$ is translation invariant and $\mathcal{H}^s(rA) = r^s \mathcal{H}^s(A)$ for $r > 0$.*
4. *If $\mathcal{H}^s(A) < \infty$ and $t > s$, then $\mathcal{H}^t(A) = 0$. If $\mathcal{H}^t(A) > 0$ and $s < t$, then $\mathcal{H}^s(A) = \infty$.*

Proof. (1) Each $\mathcal{H}^s_\delta$ is an outer measure: it is monotone, and given covers of the A_k with sums at most $\mathcal{H}^s_\delta(A_k) + \varepsilon 2^{-k}$, their union covers $\bigcup_k A_k$. Then $\mathcal{H}^s(\bigcup_k A_k) = \sup_\delta \mathcal{H}^s_\delta(\bigcup_k A_k) \le \sup_\delta \sum_k \mathcal{H}^s_\delta(A_k) \le \sum_k \mathcal{H}^s(A_k)$. If $d(A,B) > 0$ and $\delta < d(A,B)$, no set of diameter at most δ meets both A and B, so a δ-cover of $A \cup B$ splits into covers of A and of B, and $\mathcal{H}^s_\delta(A \cup B) \ge \mathcal{H}^s_\delta(A) + \mathcal{H}^s_\delta(B)$; let $\delta \to 0$. Apply Lemma 28.17.2.

(2) $\alpha(0) = 1$. A set of N points needs at least N nonempty sets of diameter less than the smallest distance between the points, and the N singletons suffice; so $\mathcal{H}^0_\delta$ of it is N for small δ. An infinite set contains finite sets of every size.

(3) If $L = 0$, then f is constant, $f(A)$ has at most one point, and the inequality is clear (with $0^0 = 1$ when $s = 0$). Let $L > 0$. If (C_k) is a δ-cover of A, then $(f(C_k \cap A))$ is an $L\delta$-cover of $f(A)$ with $\operatorname{diam} f(C_k \cap A) \le L \operatorname{diam} C_k$; so $\mathcal{H}^s_{L\delta}(f(A)) \le L^s \mathcal{H}^s_\delta(A)$. Translations are isometries, and $x \mapsto rx$ multiplies diameters by r, with inverse $x \mapsto x/r$.

(4) For a δ-cover, $\sum_k \alpha(t)(\operatorname{diam} C_k)^t \le \frac{\alpha(t)}{\alpha(s)} \delta^{t-s} \sum_k \alpha(s)(\operatorname{diam} C_k)^s$, so $\mathcal{H}^t_\delta(A) \le \frac{\alpha(t)}{\alpha(s)} \delta^{t-s} \mathcal{H}^s_\delta(A) \le \frac{\alpha(t)}{\alpha(s)} \delta^{t-s} \mathcal{H}^s(A) \to 0$. The second statement is the contrapositive. □

Remark 28.17.4.

1. *Covers may not exist.* With the convention $\inf \emptyset = +\infty$, $\mathcal{H}^s_\delta(A) = \infty$ when A has no countable cover by sets of diameter at most δ. In a separable metric space this never happens: if $\{x_k\}$ is a countable dense set, the balls $B(x_k, \delta/2)$ have diameter at most δ and cover X. In an uncountable set with the discrete metric ($d(x,y) = 1$ for $x \ne y$), sets of diameter less than 1 are points, so an uncountable set has no countable δ-cover for $\delta < 1$, and $\mathcal{H}^s$ of it is ∞ for every s, consistently with (2) for $s = 0$. All subsets of $\mathbb{R}^n$ and of manifolds are separable.

2. *Borel regularity.* $\mathcal{H}^s$ is *Borel regular*: every A is contained in a Borel set B with $\mathcal{H}^s(B) = \mathcal{H}^s(A)$. We may assume $\mathcal{H}^s(A) < \infty$. For each j choose a cover of A by closed sets $C_k^{(j)}$ of diameter at most $1/j$ with $\sum_k \alpha(s)(\operatorname{diam} C_k^{(j)})^s \le \mathcal{H}^s_{1/j}(A) + 1/j$, and let $B = \bigcap_j \bigcup_k C_k^{(j)}$, a Borel set containing A. Then $\mathcal{H}^s_{1/j}(B) \le \mathcal{H}^s_{1/j}(A) + 1/j$ for all j, so $\mathcal{H}^s(B) \le \mathcal{H}^s(A)$. On the other hand $\mathcal{H}^s$ is in general not locally finite (Example 28.3.6), hence not a Radon measure on the whole space; restricted to a set of finite $\mathcal{H}^s$-measure it is [EG92, Section 1.1].

By (4), for each A there is a unique $s_0 \in [0,\infty]$ with $\mathcal{H}^s(A) = \infty$ for $s < s_0$ and $\mathcal{H}^s(A) = 0$ for $s > s_0$; it is the *Hausdorff dimension* $\dim_{\mathcal{H}} A = \inf\{s : \mathcal{H}^s(A) = 0\}$. At $s = s_0$ the measure can be anything in $[0,\infty]$. By (3), Lipschitz maps do not increase Hausdorff dimension, and bi-Lipschitz maps preserve it.

Theorem 28.17.5. *On the Borel sets of $\mathbb{R}^n$, $\mathcal{H}^n = \lambda^n$. Consequently the subsets of $\mathbb{R}^n$ have Hausdorff dimension at most n, and nonempty open subsets have dimension n.*

Proof. We show that $\mathcal{H}^n = c\lambda^n$ for a constant $0 < c < \infty$; that $c = 1$ is the content of the *isodiametric inequality* $\lambda^n(C) \le \alpha(n)(\operatorname{diam} C)^n$, which says that among sets of given diameter the balls have the largest volume, together with Vitali's covering theorem, and we refer to [EG92, Section 2.2] for these two steps.

The constant. Let $Q = [0,1)^n$. Covering Q by m^n cubes of side $1/m$ and diameter $\sqrt{n}/m$ gives $\mathcal{H}^n_{\sqrt{n}/m}(Q) \le \alpha(n) n^{n/2}$, so $\mathcal{H}^n(Q) < \infty$. Conversely, a set C of diameter d lies in a closed box with sides d (each coordinate varies by at most d on C), so $\lambda^*(C) \le d^n$; for any cover of Q, $\sum_k \alpha(n)(\operatorname{diam} C_k)^n \ge \alpha(n) \sum_k \lambda^*(C_k) \ge \alpha(n)$, so $c = \mathcal{H}^n(Q) \ge \alpha(n) > 0$.

Comparison. $\mathcal{H}^n$ is a translation invariant measure on the Borel sets (Proposition 28.17.3). For $j \ge 0$, Q is the disjoint union of 2^{jn} translates of $[0,2^{-j})^n$, so every half-open dyadic cube $\prod_i [a_i 2^{-j}, (a_i+1)2^{-j})$ ($a_i \in \mathbb{Z}$, $j \in \mathbb{Z}$) has $\mathcal{H}^n$-measure $c2^{-jn} = c\lambda^n$ of it; for $j < 0$ use that such a cube is a disjoint union of 2^{-jn} unit cubes. Fix $m \ge 0$ and $P = [-2^m, 2^m)^n$. The dyadic cubes contained in P, together with P, form a family closed under finite intersections, on which $\mathcal{H}^n$ and $c\lambda^n$ agree and are finite. By Lemma 28.3.10 the two measures agree on the σ-algebra it generates, which contains every open subset of the interior of P (a countable union of dyadic cubes), hence every Borel subset of the interior. The boundary of P is a finite union of pieces of hyperplanes, which are null for both measures: a piece $[0,1]^{n-1} \times \{0\}$ is covered by j^{n-1} cubes of diameter $\sqrt{n}/j$, with $\sum \alpha(n)(\operatorname{diam})^n \to 0$ as $j \to \infty$. So the two measures agree on the Borel subsets of P, and letting $m \to \infty$, on all Borel sets.

The last statement follows from Proposition 28.17.3(4): $\mathcal{H}^n$ is finite on bounded sets and $\mathbb{R}^n$ is a countable union of them, so $\mathcal{H}^t = 0$ for $t > n$, while a nonempty open set has positive $\mathcal{H}^n$-measure. □

Example 28.17.6. *The Cantor set has Hausdorff dimension $s = \log 2/\log 3$, and $\alpha(s)/2 \le \mathcal{H}^s(C) \le \alpha(s)$;* note $3^s = 2$. Let $C \subseteq [0,1]$ be as in Counterexample 28.9.7. For $k \ge 0$ and digits $a_1, \dots, a_k \in \{0,2\}$ let $I_{a_1 \cdots a_k}$ be the closed interval with left end $\sum_{j \le k} a_j 3^{-j}$ and length 3^{-k}; there are 2^k of them, and C is contained in their union C_k, since the digits beyond the k-th contribute at most 3^{-k}.

1. *Upper bound.* The 2^k intervals form a 3^{-k}-cover of C with $\sum \alpha(s) 3^{-ks} = \alpha(s) 2^k 3^{-ks} = \alpha(s)$. So $\mathcal{H}^s(C) \le \alpha(s)$.

2. *Separation.* Two of these intervals of the same generation k are at distance at least 3^{-k}: if their digit strings first differ at position $j \le k$, their left ends differ by at least $2 \cdot 3^{-j} - \sum_{j<i\le k} 2 \cdot 3^{-i} = 3^{-j} + 3^{-k} \ge 2 \cdot 3^{-k}$. So a set of diameter less than 3^{-k} meets at most one of them.

3. *The Cantor measure.* Let $\mu = \mu_F$ be the measure of Lemma 28.13.3 for the Cantor function F. Since F is constant on each interval of $[0,1] \setminus C$, $\mu([0,1] \setminus C) = 0$ and $\mu(C) = F(1) - F(0) = 1$. On the generation-k interval I with left end $a = \sum_{j \le k} a_j 3^{-j}$ and right end $a + \sum_{j>k} 2 \cdot 3^{-j}$, $\mu(I) = F(a + 3^{-k}) - F(a) = \sum_{j>k} 2^{-j} = 2^{-k}$, by the formula for c on C.

4. *Lower bound.* Let U be a closed set with $0 < \operatorname{diam} U = d < 1$, and k with $3^{-k-1} \le d < 3^{-k}$. By (2), U meets at most one generation-k interval I, and $\mu(U) \le \mu(I) + \mu([0,1] \setminus C) = 2^{-k} = 3^s 3^{-(k+1)s} \le 2d^s$; for a single point, $\mu(U) = 0$. For a cover of C by closed sets U_i of diameter less than 1, $1 = \mu(C) \le \sum_i \mu(U_i \cap [0,1]) \le 2 \sum_i (\operatorname{diam} U_i)^s$. Hence $\mathcal{H}^s_\delta(C) \ge \alpha(s)/2$ for $\delta < 1$.

The argument in (4), bounding the mass that a measure on A gives to small sets, is the *mass distribution principle*, the standard way to bound Hausdorff measures from below. So the Cantor set is too small to have positive length but too large to have zero s-dimensional measure for any $s < \log 2/\log 3 \approx 0.63$.

The estimate of Proposition 28.17.3(3) for Lipschitz maps has a version for maps that are only Hölder continuous; it changes the dimension.

Proposition 28.17.7. *Let $A \subseteq X$, and let $f\colon A \to Y$ be* Hölder continuous *with exponent $0 < \gamma \le 1$ and constant $L > 0$: $d(f(x), f(y)) \le L\, d(x,y)^\gamma$ for $x, y \in A$. Then for every $s \ge 0$*

$$\mathcal{H}^{s/\gamma}(f(A)) \le \frac{\alpha(s/\gamma)}{\alpha(s)} L^{s/\gamma}\, \mathcal{H}^s(A),$$

and $\dim_{\mathcal{H}} f(A) \le \dim_{\mathcal{H}} A/\gamma$.

Proof. Let (C_k) be a cover of A by sets of diameter at most δ. The sets $f(C_k \cap A)$ cover $f(A)$ and have diameter at most $L(\operatorname{diam} C_k)^\gamma \le L\delta^\gamma$, so, with the conventions on empty sets and points made before Definition 28.17.1,

$$\sum_k \alpha(s/\gamma)(\operatorname{diam} f(C_k \cap A))^{s/\gamma} \le \alpha(s/\gamma) L^{s/\gamma} \sum_k (\operatorname{diam} C_k)^s = \frac{\alpha(s/\gamma)}{\alpha(s)} L^{s/\gamma} \sum_k \alpha(s)(\operatorname{diam} C_k)^s.$$

Hence $\mathcal{H}^{s/\gamma}_{L\delta^\gamma}(f(A)) \le \frac{\alpha(s/\gamma)}{\alpha(s)} L^{s/\gamma} \mathcal{H}^s_\delta(A)$, and we let $\delta \to 0$. If $s > \dim_{\mathcal{H}} A$, then $\mathcal{H}^s(A) = 0$, so $\mathcal{H}^{s/\gamma}(f(A)) = 0$ and $\dim_{\mathcal{H}} f(A) \le s/\gamma$. □

For $\gamma = 1$ this is the Lipschitz estimate. Hölder maps can raise the dimension by the factor $1/\gamma$, and no more.

Example 28.17.8.

1. *Graphs and projections.* The orthogonal projection $\mathbb{R}^n \to \mathbb{R}^k$ onto the first coordinates is 1-Lipschitz, so it does not increase $\mathcal{H}^s$. For a function $g\colon [0,1] \to \mathbb{R}$, the projection maps the graph Γ_g onto $[0,1]$, so $\mathcal{H}^1(\Gamma_g) \ge \mathcal{H}^1([0,1]) = 1$ by Theorem 28.17.5: a graph is at least as long as its domain. Similarly a set $A \subseteq \mathbb{R}^2$ with $\dim_{\mathcal{H}} A < 1$ projects onto a Lebesgue null subset of every line.

2. *Space-filling curves are not Lipschitz.* There are continuous surjections $g\colon [0,1] \to [0,1]^2$ (Theorem 18.14.4). If such a map were Hölder with exponent γ_0, the proposition would give $2 = \dim_{\mathcal{H}}[0,1]^2 \le \dim_{\mathcal{H}}[0,1]/\gamma_0 = 1/\gamma_0$, using Theorem 28.17.5 for both dimensions. So a space-filling curve is never Hölder with an exponent larger than $\frac{1}{2}$, in particular never Lipschitz.

3. *The Cantor function is Hölder.* Let C be the Cantor set and $s = \log 2/\log 3$, and let $\varphi\colon C \to [0,1]$ send $\sum_n 2a_n 3^{-n}$ to $\sum_n a_n 2^{-n}$ ($a_n \in \{0,1\}$), a continuous surjection (Proposition 18.14.3). If $x \neq y$ in C have digit sequences first differing at position n, then $|x-y| \geq 3^{-n}$ (by the proof of Proposition 18.14.2(1)) and $|\varphi(x)-\varphi(y)| \leq \sum_{m\geq n} 2^{-m} = 2\cdot 2^{-n} = 2(3^{-n})^s \leq 2|x-y|^s$. So φ is Hölder with exponent s and constant 2, and the proposition with exponent $\gamma = s$, applied in dimension s, gives

$$1 = \mathcal{H}^1([0,1]) \leq \frac{\alpha(1)}{\alpha(s)} 2^{1/s} \mathcal{H}^s(C) = \frac{3}{\alpha(s)} \mathcal{H}^s(C),$$

as $\alpha(1) = 1$ and $2^{1/s} = 2^{\log 3/\log 2} = 3$. So $\mathcal{H}^s(C) \geq \alpha(s)/3 > 0$: a new proof that $\dim_{\mathcal{H}} C \geq s$, slightly weaker than the bound $\alpha(s)/2$ of Example 28.17.6, which used the Cantor measure.

4. *Bi-Lipschitz invariance.* If f is bi-Lipschitz, $L^{-1}d(x,y) \leq d(f(x),f(y)) \leq Ld(x,y)$, then $L^{-s}\mathcal{H}^s(A) \leq \mathcal{H}^s(f(A)) \leq L^s\mathcal{H}^s(A)$, so Hausdorff dimension, and finiteness and positivity of $\mathcal{H}^s$, are bi-Lipschitz invariants. They are not topological invariants. On $\mathbb{R}$ the *snowflake metric* $d(x,y) = |x-y|^{1/2}$ is a metric (as $\sqrt{a+b} \leq \sqrt{a} + \sqrt{b}$) with the same open sets as the usual one, since its balls are the usual balls with squared radii. A set C has d-diameter $(\operatorname{diam} C)^{1/2}$, so the covers in the definition give $\mathcal{H}^s_d = \frac{\alpha(s)}{\alpha(s/2)}\mathcal{H}^{s/2}$, and $[0,1]$ has dimension 2 for d. The identity $(\mathbb{R}, |\cdot|) \to (\mathbb{R}, d)$ is a homeomorphism, Hölder with exponent $\frac{1}{2}$, which doubles all dimensions.

28.18 Self-similar sets

The Cantor set C is the union of two copies of itself, $C/3$ and $C/3 + 2/3$, each scaled by the factor $\frac{1}{3}$. If we only knew that $0 < \mathcal{H}^s(C) < \infty$ for some s, the scaling property of Proposition 28.17.3(3) would already give the value of s: the two copies are disjoint Borel sets, so $\mathcal{H}^s(C) = 2\cdot 3^{-s}\mathcal{H}^s(C)$, and $3^s = 2$. Many sets that come up in analysis and dynamics, usually called *fractals*, are built in the same way from finitely many scaled copies of themselves, and their dimension can be read off from the scaling factors. This section makes the heuristic rigorous: we construct such sets in general (Theorem 28.18.5), and compute their dimension when the copies are disjoint (Theorem 28.18.10). Along the way we meet a second notion of dimension, which is cruder than the Hausdorff dimension but easier to compute. References: [Fal90], [Hut81].

28.18.1 Box-counting dimension

Hausdorff measure allows covers by sets of very different sizes, and this is what makes it a measure. If instead we cover a set by sets of one fixed size δ and only count them, we get a simpler quantity. A segment of length 1 needs about $1/\delta$ sets of diameter δ, a square about δ^{-2}, a cube about δ^{-3}: the exponent is the dimension.

Definition 28.18.1. For a nonempty bounded $A \subseteq \mathbb{R}^n$ and $\delta > 0$, let $N_\delta(A)$ be the smallest number of sets of diameter at most δ that cover A. The *lower* and *upper box-counting dimensions* of A are

$$\underline{\dim}_B A = \liminf_{\delta\to 0} \frac{\log N_\delta(A)}{-\log\delta}, \qquad \overline{\dim}_B A = \limsup_{\delta\to 0} \frac{\log N_\delta(A)}{-\log\delta}.$$

If they are equal, their common value is the *box-counting dimension* $\dim_B A$.

The number $N_\delta(A)$ is finite: A lies in a cube, which is a finite union of small cubes. The definition says that $N_\delta(A)$ is roughly $\delta^{-\dim_B A}$; more precisely, $\overline{\dim}_B A < t$ if and only if $N_\delta(A) \le \delta^{-t'}$ for some $t' < t$ and all small δ.

Proposition 28.18.2. *Let $A, A_1, A_2, \ldots$ be subsets of $\mathbb{R}^n$.*

1. *(*Countable stability*)* $\dim_{\mathcal{H}} \bigcup_k A_k = \sup_k \dim_{\mathcal{H}} A_k$. *In particular countable sets have Hausdorff dimension* 0.

2. *If A is nonempty and bounded, $N_\delta(A) = N_\delta(\overline{A})$, so A and its closure have the same box-counting dimensions.*

3. *If A is nonempty and bounded,* $\dim_{\mathcal{H}} A \le \underline{\dim}_B A \le \overline{\dim}_B A \le n$.

Proof. (1) Since $\mathcal{H}^s$ is monotone, $\dim_{\mathcal{H}} A_k \le \dim_{\mathcal{H}} \bigcup_k A_k$ for every k. Conversely, if $s > \sup_k \dim_{\mathcal{H}} A_k$, then $\mathcal{H}^s(A_k) = 0$ for every k, and $\mathcal{H}^s(\bigcup_k A_k) = 0$ by countable subadditivity; so $\dim_{\mathcal{H}} \bigcup_k A_k \le s$. A point has $\mathcal{H}^s$-measure 0 for every $s > 0$, since it is covered by one set of diameter 0; so a point has dimension 0, and so has a countable set.

(2) A cover of A by sets of diameter at most δ gives the cover of $\overline{A}$ by their closures, which have the same diameters, since a finite union of closed sets is closed. So $N_\delta(\overline{A}) \le N_\delta(A)$, and the other inequality holds as $A \subseteq \overline{A}$.

(3) The middle inequality is clear. For the last one, let A lie in a cube of side ℓ. Dividing it into m^n cubes of side ℓ/m, of diameter $\ell\sqrt{n}/m$, with m the smallest integer $\ge \ell\sqrt{n}/\delta$, gives $N_\delta(A) \le m^n \le (\ell\sqrt{n}/\delta + 1)^n$, and $\log N_\delta(A)/(-\log\delta) \le n \log(\ell\sqrt{n} + \delta)/(-\log\delta) + n$, whose lim sup as $\delta \to 0$ is n. For the first inequality, let $s > t > \underline{\dim}_B A$. There are $\delta_j \to 0$ with $\log N_{\delta_j}(A) < t(-\log\delta_j)$, that is, $N_{\delta_j}(A) < \delta_j^{-t}$. Covering A by $N_{\delta_j}(A)$ sets of diameter at most δ_j gives

$$\mathcal{H}^s_{\delta_j}(A) \le \alpha(s) N_{\delta_j}(A) \delta_j^s \le \alpha(s) \delta_j^{s-t} \to 0.$$

As $\mathcal{H}^s_\delta(A)$ increases when δ decreases, $\mathcal{H}^s(A) = \lim_j \mathcal{H}^s_{\delta_j}(A) = 0$, so $\dim_{\mathcal{H}} A \le s$. Since $s > \underline{\dim}_B A$ was arbitrary, the inequality follows. □

By (2), box-counting dimension cannot see the difference between a set and its closure: $\mathbb{Q} \cap [0,1]$ has box-counting dimension 1, like $[0,1]$, while its Hausdorff dimension is 0 by (1). So box-counting dimension is not countably stable, and in general it is not attached to a measure. The inequality in (3) can be strict even for compact sets.

Example 28.18.3. *A compact countable set of box-counting dimension $\frac{1}{2}$.* Let $E = \{0\} \cup \{1/m : m \ge 1\}$. It is countable, so $\dim_{\mathcal{H}} E = 0$. We show that $\dim_B E = \frac{1}{2}$. Let $0 < \delta < 1$.

1. *Lower bound.* Let $m = \lfloor \delta^{-1/2} \rfloor \ge 1$. For $2 \le j \le m$ the consecutive points $1/(j-1)$ and $1/j$ are at distance $\frac{1}{j(j-1)} > \frac{1}{m^2} \ge \delta$. So the points $1, \frac{1}{2}, \ldots, \frac{1}{m}$ are pairwise more than δ apart, a set of diameter at most δ contains at most one of them, and $N_\delta(E) \ge m > \delta^{-1/2} - 1$.

2. *Upper bound.* Let $m = \lceil \delta^{-1/2} \rceil$. The interval $[0, \frac{1}{m}]$, which contains all points $1/j$ with $j \ge m$, is covered by $\lceil \frac{1}{m\delta} \rceil$ intervals of length δ, and the remaining $m-1$ points are covered by singletons. Since $m - 1 < \delta^{-1/2}$ and $\frac{1}{m\delta} \le \delta^{-1/2}$, $N_\delta(E) \le 2\delta^{-1/2} + 1 \le 3\delta^{-1/2}$.

Taking logarithms, $\log(\delta^{-1/2} - 1)/(-\log\delta)$ and $(\log 3 + \frac{1}{2}(-\log\delta))/(-\log\delta)$ both tend to $\frac{1}{2}$ as $\delta \to 0$. The reason is that the points $1/j$ are spread out for j small and crowded for j large: at scale δ one sees about $\delta^{-1/2}$ separate points, and the rest look like an interval of length about $\delta^{1/2}$.

28.18.2 Iterated function systems

A map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ is a *similarity with ratio* $r > 0$ if $|f(x) - f(y)| = r|x - y|$ for all x, y; for example $f(x) = rOx + b$ with O orthogonal (every similarity has this form, but we do not need this). A similarity with ratio r multiplies diameters by r, and by Proposition 28.17.3(3), applied to f and to its inverse, $\mathcal{H}^s(f(A)) = r^s\mathcal{H}^s(A)$ for every A and s.

Definition 28.18.4. An *iterated function system* (of similarities) is a finite family $f_1, \dots, f_N$ of similarities of $\mathbb{R}^n$ with ratios $r_1, \dots, r_N \in (0, 1)$, where $N \geq 2$. For a set A write $F(A) = f_1(A) \cup \cdots \cup f_N(A)$. A nonempty compact set K with $F(K) = K$ is called the *attractor* of the system, or a *self-similar set*.

It is convenient to use words in the alphabet $\{1, \dots, N\}$. For a word $w = w_1 \cdots w_k$ of length $|w| = k$ let

$$f_w = f_{w_1} \circ f_{w_2} \circ \cdots \circ f_{w_k}, \qquad r_w = r_{w_1} r_{w_2} \cdots r_{w_k},$$

so that f_w is a similarity with ratio r_w; for the empty word $\varnothing$, $f_\varnothing$ is the identity and $r_\varnothing = 1$. Write wi for the word w followed by the letter i, and $r = \max_i r_i < 1$, so that $r_w \leq r^{|w|}$. For an infinite sequence $\omega = \omega_1\omega_2 \cdots$ of letters, $\omega|k = \omega_1 \cdots \omega_k$ is its beginning of length k. Since $F(A) = \bigcup_i f_i(A)$, induction on k gives $F^k(A) = \bigcup_{|w|=k} f_w(A)$.

Theorem 28.18.5 (Hutchinson)**.** *Every iterated function system has a unique attractor K. Moreover:*

1. *If B is a nonempty compact set with $F(B) \subseteq B$, then $K = \bigcap_k F^k(B)$; in particular $K \subseteq B$.*
2. *Let $K_w = f_w(K)$. Then $K = \bigcup_{|w|=k} K_w$ for every k, and $K_w = \bigcup_i K_{wi}$, with* $\operatorname{diam} K_w = r_w \operatorname{diam} K$.
3. *Every $x \in K$ has an* address*: an infinite sequence ω with $x \in K_{\omega|k}$ for all k. For every infinite sequence ω, $\bigcap_k K_{\omega|k}$ is a single point.*

Proof. Existence, and (1). First, a compact set B with $F(B) \subseteq B$ exists: let $R = \max_i |f_i(0)|/(1-r)$ and let B be the closed ball of radius R about 0. For $|x| \leq R$, $|f_i(x)| \leq |f_i(x) - f_i(0)| + |f_i(0)| \leq rR + (1 - r)R = R$. Now let B be any nonempty compact set with $F(B) \subseteq B$. Applying F, which preserves inclusions, gives $B \supseteq F(B) \supseteq F^2(B) \supseteq \cdots$, a decreasing sequence of nonempty compact sets (finite unions of continuous images of compact sets). Their intersection K is nonempty and compact. To see $F(K) = K$, note that $f_i(K) = \bigcap_k f_i(F^k(B))$ since f_i is injective, so

$$F(K) = \bigcup_i \bigcap_k f_i(F^k(B)) \qquad \text{and} \qquad K = \bigcap_k F^{k+1}(B) = \bigcap_k \bigcup_i f_i(F^k(B)).$$

The first set is contained in the second. Conversely, if x lies in $\bigcup_i f_i(F^k(B))$ for every k, then there is one i with $x \in f_i(F^k(B))$ for infinitely many k, and so for all k, as these sets decrease with k. So the two sets are equal.

Uniqueness. Let A and K be nonempty compact sets with $F(A) = A$ and $F(K) = K$, and $D = \max\{|a - y| : a \in A, y \in K\}$. Fix k. Since $A = F^k(A)$, every $a \in A$ is $f_w(a')$ for a word w of length k and some $a' \in A$. For any $y \in K$, the point $f_w(y)$ lies in $F^k(K) = K$, and $|a - f_w(y)| = r_w|a' - y| \leq r^k D$. So every point of A is within $r^k D$ of K, for every k; as K is closed, $A \subseteq K$. By symmetry $K \subseteq A$.

(2) The first statement is $K = F^k(K)$, the second is $f_w(K) = f_w(F(K)) = \bigcup_i f_w(f_i(K))$, and the third holds because f_w multiplies distances by r_w.

(3) Since $K = \bigcup_i f_i(K)$, a point $x \in K$ can be written $x = f_{\omega_1}(x_1)$ with $x_1 \in K$; then $x_1 = f_{\omega_2}(x_2)$ with $x_2 \in K$, and so on. Then $x = f_{\omega|k}(x_k) \in K_{\omega|k}$ for all k. For any ω, the sets $K_{\omega|k}$ are nonempty, compact, decreasing by (2), and of diameter at most $r^k \operatorname{diam} K \to 0$; so their intersection is one point. □

Remark 28.18.6. Hutchinson's original proof [Hut81] is an application of the Banach fixed point theorem. The nonempty compact subsets of $\mathbb{R}^n$ form a complete metric space for the *Hausdorff distance* $d_H(A,B) = \inf\{\varepsilon > 0 : A \subseteq B_\varepsilon, B \subseteq A_\varepsilon\}$, where A_ε is the set of points at distance less than ε from A, and F is a contraction with constant r for this distance; the attractor is its fixed point, and $F^k(B) \to K$ for every nonempty compact B. This also explains the name: starting from any picture B, repeatedly replacing it by N smaller copies of itself converges to K. The uniqueness proof above is the contraction argument in disguise.

Example 28.18.7. 1. *The Cantor set.* $f_1(x) = x/3$, $f_2(x) = x/3 + 2/3$ on $\mathbb{R}$. The Cantor set C, the set of $\sum_k a_k 3^{-k}$ with all $a_k \in \{0,2\}$, satisfies $f_1(C) = \{a_1 = 0\}$ and $f_2(C) = \{a_1 = 2\}$, so $F(C) = C$ and C is the attractor. The sets C_w are the parts of C in the intervals I_w of Example 28.17.6, and the address of a point is its sequence of ternary digits, with 1 and 2 standing for the digits 0 and 2.

2. *An interval.* $f_1(x) = x/2$, $f_2(x) = x/2 + 1/2$. Here $F([0,1]) = [0,1]$, so the attractor is $[0,1]$; addresses are binary expansions, and the dyadic rationals have two addresses.

3. *The Sierpiński gasket.* Let p_1, p_2, p_3 be the vertices of a triangle T in $\mathbb{R}^2$ and $f_i(x) = (x+p_i)/2$. Then $f_i(T)$ is the triangle with vertex p_i and the midpoints of the two sides through p_i, so $F(T) \subseteq T$ and the attractor is $S = \bigcap_k F^k(T)$ by (1): at each step every triangle is replaced by its three corner triangles, and the open middle one is removed.

4. *The Koch curve.* In $\mathbb{R}^2 = \mathbb{C}$ let $\zeta = e^{i\pi/3}$ and

$$f_1(z) = \tfrac{z}{3}, \quad f_2(z) = \tfrac{\zeta z + 1}{3}, \quad f_3(z) = \tfrac{\bar\zeta z}{3} + \tfrac12 + \tfrac{i\sqrt3}{6}, \quad f_4(z) = \tfrac{z+2}{3}.$$

   They map the segment $[0,1]$ to the four sides of the polygon $0, \frac13, \frac12 + \frac{i\sqrt3}{6}, \frac23, 1$, whose middle part is the tip of an equilateral triangle erected on the middle third of $[0,1]$: for instance $f_2(1) = \frac{1+\zeta}{3} = \frac12 + \frac{i\sqrt3}{6} = f_3(0)$ and $f_3(1) = \frac{\bar\zeta}{3} + \frac12 + \frac{i\sqrt3}{6} = \frac23 = f_4(0)$. The attractor is the limit of the polygons $F^k([0,1])$, in the sense of Remark 28.18.6.

5. *The four-corner Cantor set.* For $a \in \{0, \frac34\}^2$ let $f_a(x) = \frac{x}{4} + a$ on $\mathbb{R}^2$. The four squares $f_a([0,1]^2)$ are the corner squares of side $\frac14$ of the unit square, so the attractor $K_4 \subseteq [0,1]^2$ is obtained by repeatedly replacing every square by its four corner squares of a quarter of the size. It contains the fixed points $(0,0)$ and $(1,1)$ of $f_{(0,0)}$ and $f_{(3/4,3/4)}$, so $\operatorname{diam} K_4 = \sqrt2$.

28.18.3 The similarity dimension

The function $s \mapsto \sum_i r_i^s$ is continuous and strictly decreasing on $[0,\infty)$, equal to $N \geq 2$ at $s = 0$ and tending to 0 as $s \to \infty$. So there is a unique $s > 0$ with

$$r_1^s + r_2^s + \cdots + r_N^s = 1, \tag{28.2}$$

the *similarity dimension* of the system. If all ratios equal ρ, then $N\rho^s = 1$ and $s = \log N / \log(1/\rho)$: for the Cantor set $s = \log 2/\log 3$, for the interval of Example 28.18.7(2) $s = 1$, for the Sierpiński gasket $s = \log 3/\log 2 \approx 1.585$, for the Koch curve $s = \log 4/\log 3 \approx 1.262$, and for the four-corner set $s = \log 4/\log 4 = 1$. To cover K efficiently by the pieces K_w one should use pieces of comparable sizes, not of equal word length; the following lemma organises this.

Lemma 28.18.8. *For $0 < \rho < 1$ let Q_ρ be the set of nonempty words w with $r_w \le \rho < r_{w^-}$, where w^- is w with its last letter removed. Then every infinite sequence ω has exactly one beginning $\omega|k$ in Q_ρ, the set Q_ρ is finite, and*

$$\sum_{w\in Q_\rho} r_w^s = 1, \qquad \#Q_\rho \le (\rho\, r_{\min})^{-s}, \qquad K = \bigcup_{w\in Q_\rho} K_w,$$

where s is the similarity dimension and $r_{\min} = \min_i r_i$.

Proof. Along ω the numbers $r_{\omega|k}$ decrease strictly from $r_{\omega|0} = 1 > \rho$ to 0, so there is exactly one $k \ge 1$ with $r_{\omega|k} \le \rho < r_{\omega|(k-1)}$. Let k_0 be such that $r^{k_0} \le \rho$. Every word w of length at least $k_0 + 1$ has $r_{w^-} \le r^{k_0} \le \rho$, so it is not in Q_ρ; hence Q_ρ is finite. Every word v of length k_0 has $r_v \le \rho$, so, applying the first statement to any infinite sequence beginning with v, v has exactly one beginning in Q_ρ. Grouping the words of length k_0 according to this beginning, and using that the words of length k_0 extending a given w are the wu with $|u| = k_0 - |w|$,

$$1 = \Big(\sum_i r_i^s\Big)^{k_0} = \sum_{|v|=k_0} r_v^s = \sum_{w\in Q_\rho}\ \sum_{|u|=k_0-|w|} r_w^s r_u^s = \sum_{w\in Q_\rho} r_w^s \Big(\sum_i r_i^s\Big)^{k_0-|w|} = \sum_{w\in Q_\rho} r_w^s.$$

Each $w \in Q_\rho$ has $r_w = r_{w^-} r_{w_{|w|}} > \rho\, r_{\min}$, so $1 \ge \#Q_\rho\, (\rho\, r_{\min})^s$. Finally, if $x \in K$ has address ω and $\omega|k \in Q_\rho$, then $x \in K_{\omega|k}$. □

Proposition 28.18.9. *Let K be the attractor of an iterated function system with similarity dimension s. Then $\mathcal{H}^s(K) \le \alpha(s)(\operatorname{diam} K)^s$, and $\dim_{\mathcal{H}} K \le \overline{\dim}_B K \le s$.*

Proof. We may assume $d = \operatorname{diam} K > 0$. For $0 < \rho < 1$ the sets K_w, $w \in Q_\rho$, cover K by Lemma 28.18.8 and have diameter $r_w d \le \rho d$, so

$$\mathcal{H}^s_{\rho d}(K) \le \sum_{w\in Q_\rho} \alpha(s)(r_w d)^s = \alpha(s) d^s,$$

and $\rho \to 0$ gives the first claim. With $\delta = \rho d$ they also show $N_\delta(K) \le \#Q_\rho \le (r_{\min}\delta/d)^{-s}$ for $0 < \delta < d$, so $\log N_\delta(K)/(-\log\delta) \le s + s\log(d/r_{\min})/(-\log\delta)$, whose lim sup is s. The remaining inequality is Proposition 28.18.2(3). □

The upper bound can be far from the truth when the pieces overlap: for $f_1(x) = f_2(x) = x/2$ the attractor is the point $\{0\}$, while $s = 1$. The lower bound needs a condition which prevents such overlaps. The simplest one is that the pieces are disjoint.

Theorem 28.18.10. *Let K be the attractor of an iterated function system with similarity dimension s, and suppose that the sets $f_1(K), \dots, f_N(K)$ are pairwise disjoint (the* strong separation condition*). Then*

$$\alpha(s)(r_{\min}\eta)^s \le \mathcal{H}^s(K) \le \alpha(s)(\operatorname{diam} K)^s, \qquad \eta = \min_{i\ne j} d(f_i(K), f_j(K)) > 0,$$

and $\dim_{\mathcal{H}} K = \dim_B K = s$.

Proof. Step 1: separation at all scales. $\eta > 0$ because the $f_i(K)$ are disjoint compact sets. For a word w and $i \ne j$, f_w multiplies distances by r_w, so $d(K_{wi}, K_{wj}) = r_w d(f_i(K), f_j(K)) \ge r_w\eta$. Let $x, y \in K$ with addresses ω and ω', and suppose these first differ at position j; let $u = \omega|(j-1)$. Then $x \in K_{u\omega_j}$ and $y \in K_{u\omega'_j}$, so

$$|x - y| \ge r_{\omega|(j-1)}\,\eta. \tag{28.3}$$

In particular, for each k the N^k sets K_w with $|w| = k$ are pairwise disjoint, and each of them is open in K, its complement in K being the finite union of the others, which is compact.

Step 2: the natural measure. Put $p_w = r_w^s$, so that $\sum_i p_{wi} = p_w \sum_i r_i^s = p_w$, and by induction $\sum_{|u|=l} p_{wu} = p_w$ for every l. Fix $x_0 \in K$, put $x_w = f_w(x_0) \in K_w$, and for $\varphi \in C(K)$ let

$$S_k(\varphi) = \sum_{|w|=k} p_w \, \varphi(x_w).$$

Let $\omega_\varphi(t) = \sup\{|\varphi(x) - \varphi(y)| : |x - y| \le t\}$, which tends to 0 as $t \to 0$ since φ is uniformly continuous on the compact set K. For $l > k$, regrouping the words of length l by their beginnings of length k,

$$|S_l(\varphi) - S_k(\varphi)| = \Big| \sum_{|w|=k} \sum_{|u|=l-k} p_{wu} \big(\varphi(x_{wu}) - \varphi(x_w)\big) \Big| \le \omega_\varphi(r^k \operatorname{diam} K) \sum_{|w|=k} p_w = \omega_\varphi(r^k \operatorname{diam} K),$$

since x_{wu} and x_w both lie in K_w. So $(S_k(\varphi))_k$ is a Cauchy sequence, and $\Lambda(\varphi) = \lim_k S_k(\varphi)$ is a positive linear functional on $C(K) = C_c(K)$ with $\Lambda(1) = 1$. By the Riesz–Markov theorem (Theorem 28.14.6) there is a Borel probability measure μ on K with $\int \varphi \, d\mu = \Lambda(\varphi)$. By Step 1 the indicator function $\mathbf{1}_{K_w}$ is continuous on K, and for $l \ge k = |w|$ the points x_v with $|v| = l$ lying in K_w are those with v beginning with w. Hence

$$\mu(K_w) = \lim_l S_l(\mathbf{1}_{K_w}) = \sum_{|u|=l-k} p_{wu} = p_w = r_w^s.$$

Step 3: the mass of small sets. Let U be a closed set with $d = \operatorname{diam} U < \eta$; we show $\mu(U \cap K) \le (d/(r_{\min}\eta))^s$. This is clear if $U \cap K = \emptyset$. Let $x \in U \cap K$ have address ω. If $d = 0$, then $\mu(U \cap K) = \mu(\{x\}) \le \mu(K_{\omega|k}) = r_{\omega|k}^s \to 0$. If $d > 0$, the numbers $r_{\omega|k}\eta$ decrease from $\eta > d$ to 0, so there is a least $k \ge 1$ with $r_{\omega|k}\eta \le d$, and $r_{\omega|(k-1)}\eta > d$. Every $y \in U \cap K$ lies in $K_{\omega|(k-1)}$: otherwise an address of y first differs from ω at a position $j \le k-1$, and (28.3) gives $|x - y| \ge r_{\omega|(j-1)}\eta \ge r_{\omega|(k-1)}\eta > d$, which is impossible. Therefore

$$\mu(U \cap K) \le \mu(K_{\omega|(k-1)}) = r_{\omega|(k-1)}^s \le \left(\frac{d}{r_{\min}\eta}\right)^s,$$

the last step because $d \ge r_{\omega|k}\eta = r_{\omega|(k-1)} r_{\omega_k} \eta \ge r_{\omega|(k-1)} r_{\min}\eta$.

Step 4: conclusion. Let $\delta < \eta$ and let (U_i) be a cover of K by closed sets of diameter at most δ; closed covers suffice to compute $\mathcal{H}^s_\delta$. By Step 3,

$$1 = \mu(K) \le \sum_i \mu(U_i \cap K) \le (r_{\min}\eta)^{-s} \sum_i (\operatorname{diam} U_i)^s,$$

so $\mathcal{H}^s_\delta(K) \ge \alpha(s)(r_{\min}\eta)^s$, and the lower bound follows. With Proposition 28.18.9, $0 < \mathcal{H}^s(K) < \infty$, so $\dim_{\mathcal{H}} K = s$, and $s = \dim_{\mathcal{H}} K \le \underline{\dim}_B K \le \overline{\dim}_B K \le s$ by Proposition 28.18.2(3). □

Step 3 is the mass distribution principle of Example 28.17.6 again; the new ingredient is that the measure is built for us by the Riesz–Markov theorem, once we know what it should give to the pieces K_w. The measure μ is in fact the normalised restriction of $\mathcal{H}^s$ to K (Exercise 28.23.20).

Example 28.18.11. 1. *The Cantor set.* $f_1(C) \subseteq [0, \frac{1}{3}]$ and $f_2(C) \subseteq [\frac{2}{3}, 1]$ are disjoint, at distance $\eta = \frac{1}{3}$, the distance between the points $\frac{1}{3}$ and $\frac{2}{3}$ of C. The theorem gives $\dim_{\mathcal{H}} C = \dim_B C = \log 2/\log 3$ and $\alpha(s)/4 \le \mathcal{H}^s(C) \le \alpha(s)$, as $(r_{\min}\eta)^s = 9^{-s} = \frac{1}{4}$; the direct argument of Example 28.17.6 gave the better lower bound $\alpha(s)/2$. In fact $\mathcal{H}^s(C) = \alpha(s)$ [Fal90], but this requires a finer argument.

2. *A totally disconnected set of dimension* 1. For the four-corner set K_4 of Example 28.18.7(5) the four pieces lie in the four corner squares of side $\frac{1}{4}$, which are pairwise at distance at least $\frac{1}{2}$. So $\dim_{\mathcal{H}} K_4 = 1$ and $0 < \mathcal{H}^1(K_4) \le \alpha(1)\sqrt{2} = \sqrt{2}$ (note $\alpha(1) = 1$). Yet K_4 contains no segment, indeed no connected set with more than one point: the sets $(K_4)_w$ are open and closed in K_4 by Step 1, and every point has such neighbourhoods of arbitrarily small diameter. So K_4 has the dimension and the finite positive length of a curve, but none of its geometry; Example 28.18.12 and Section 28.22 return to this.

3. *Products.* $C \times C \subseteq \mathbb{R}^2$ is the attractor of the four maps $(x, y) \mapsto (x/3 + a, y/3 + b)$ with $a, b \in \{0, \frac{2}{3}\}$ (by uniqueness, since $C \times C$ is compact and invariant), whose images lie in the four corner squares of side $\frac{1}{3}$. So $\dim_{\mathcal{H}}(C \times C) = \log 4/\log 3 = 2 \dim_{\mathcal{H}} C$.

4. *Middle-λ Cantor sets.* Removing open middle intervals of relative length $\lambda \in (0, 1)$ instead of $\frac{1}{3}$ gives the attractor of $x \mapsto \rho x$ and $x \mapsto \rho x + 1 - \rho$ with $\rho = (1 - \lambda)/2$, of dimension $\log 2/\log(2/(1 - \lambda))$. As λ runs through $(0, 1)$ this takes every value in $(0, 1)$.

Example 28.18.12. *Shadows of the four-corner set.* Let K_4 be as in Example 28.18.7(5). Its projection $\pi_1(x, y) = x$ to the first axis satisfies $\pi_1 \circ f_a = g_{a_1} \circ \pi_1$ with $g_0(t) = t/4$ and $g_{3/4}(t) = t/4 + \frac{3}{4}$. So $\pi_1(K_4)$ is a nonempty compact set with $\pi_1(K_4) = g_0(\pi_1(K_4)) \cup g_{3/4}(\pi_1(K_4))$, the attractor of $\{g_0, g_{3/4}\}$, whose pieces lie in $[0, \frac{1}{4}]$ and $[\frac{3}{4}, 1]$. By Theorem 28.18.10 it has dimension $\log 2/\log 4 = \frac{1}{2}$, hence length 0. Now project instead by $\pi(x, y) = x + y/2$. Then $\pi \circ f_a = h_a \circ \pi$ with $h_a(t) = t/4 + \pi(a)$, and $\pi(a)$ runs through $0, \frac{3}{8}, \frac{3}{4}, \frac{9}{8}$ as a runs through $(0, 0), (0, \frac{3}{4}), (\frac{3}{4}, 0), (\frac{3}{4}, \frac{3}{4})$. The interval $[0, \frac{3}{2}]$ satisfies

$$\bigcup_a h_a\big([0, \tfrac{3}{2}]\big) = [0, \tfrac{3}{8}] \cup [\tfrac{3}{8}, \tfrac{3}{4}] \cup [\tfrac{3}{4}, \tfrac{9}{8}] \cup [\tfrac{9}{8}, \tfrac{3}{2}] = [0, \tfrac{3}{2}],$$

so by uniqueness of attractors $\pi(K_4) = [0, \frac{3}{2}]$. The orthogonal projection onto the line spanned by $(2, 1)$ is $\frac{2}{\sqrt{5}}\pi$ up to an isometry of the line, so the shadow of K_4 in this direction has length $\frac{3}{\sqrt{5}}$, while in the direction of the first axis it has length 0. As orthogonal projections are 1-Lipschitz, this also gives

$$\frac{3}{\sqrt{5}} \le \mathcal{H}^1(K_4) \le \sqrt{2},$$

that is, $1.341\ldots \le \mathcal{H}^1(K_4) \le 1.414\ldots$, a much better lower bound than Theorem 28.18.10 gives.

Remark 28.18.13. *Touching pieces.* For the Sierpiński gasket and the Koch curve the pieces $f_i(K)$ touch, so Theorem 28.18.10 does not apply, and Proposition 28.18.9 only gives the upper bounds $\log 3/\log 2$ and $\log 4/\log 3$ for their dimensions. Equality holds under the weaker *open set condition*: there is a nonempty bounded open set V with $f_i(V) \subseteq V$ and the $f_i(V)$ pairwise disjoint (for the gasket, the open triangle; for the Koch curve, the open isosceles triangle with base $[0, 1]$ and apex $\frac{1}{2} + \frac{i\sqrt{3}}{6}$). Under this condition $0 < \mathcal{H}^s(K) < \infty$ and $\dim_{\mathcal{H}} K = \dim_B K = s$ [Hut81], [Fal90, Chapter 9]. The proof follows the same plan: the natural measure exists without any condition, and the open set condition replaces (28.3) by a volume argument showing that a ball of radius ρ meets a bounded number of pieces K_w, $w \in Q_\rho$.

28.19 Lipschitz maps and Rademacher's theorem

A Lipschitz function of one variable is absolutely continuous, hence differentiable almost everywhere (Example 28.13.5). Rademacher's theorem extends this to several variables. It is

the reason why Lipschitz maps are the natural class of maps in geometric measure theory: they are just regular enough to have a derivative almost everywhere, and they are preserved by the operations of the theory (distance functions, compositions, restrictions, inverses of bi-Lipschitz maps), which smooth maps are not.

Lemma 28.19.1. *If $g \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$ and $\int g\varphi \, d\lambda = 0$ for all compactly supported functions φ of class C^1, then $g = 0$ almost everywhere.*

Proof. Let $\psi(s) = 3s^2 - 2s^3$ for $0 \le s \le 1$, $\psi = 0$ for $s < 0$ and $\psi = 1$ for $s > 1$, a C^1 function. For a ball $B(x,r)$ and $j > 1/r$ let $\varphi_j(y) = \psi(j(r - \|y - x\|))$; it is C^1, since it is constant near $y = x$, takes values in $[0,1]$, vanishes outside $B(x,r)$, and $\varphi_j \to \mathbf{1}_{B(x,r)}$ pointwise. By dominated convergence $\int_{B(x,r)} g = 0$ for all balls, and by the Lebesgue differentiation theorem (Theorem 28.9.4), $g(x) = \lim_{r\to 0} A_r g(x) = 0$ for almost every x. □

Theorem 28.19.2 (Rademacher)**.** *Every Lipschitz map $f : \mathbb{R}^n \to \mathbb{R}^m$ is differentiable at almost every point of $\mathbb{R}^n$.*

Proof. It suffices to treat $m = 1$, applying the result to the components. Let L be a Lipschitz constant. For a unit vector v and $x \in \mathbb{R}^n$ let $D_v f(x) = \lim_{t\to 0}(f(x + tv) - f(x))/t$ where the limit exists.

Step 1: for each v, $D_v f(x)$ exists for almost every x. As the difference quotients are continuous in $t \neq 0$, the limit exists if and only if the lim sup and lim inf over rational $t \to 0$ are equal and finite, so the set N_v where it fails is Borel, and $D_v f$ is Borel measurable where defined, with $|D_v f| \le L$. Choose an orthogonal map R with $Re_1 = v$; it preserves λ (Lemma 28.11.1), and $f \circ R$ is Lipschitz. For each $y \in \mathbb{R}^{n-1}$, $t \mapsto f(R(t,y))$ is a Lipschitz function of one variable, differentiable almost everywhere (Example 28.13.5); so every line parallel to e_1 meets $R^{-1}(N_v)$ in a null set, and by Tonelli's theorem (Theorem 28.10.3) $\lambda(N_v) = \lambda(R^{-1}(N_v)) = 0$. In particular the gradient $\nabla f = (D_{e_1} f, \dots, D_{e_n} f)$ exists almost everywhere, and $|\nabla f| \le \sqrt{n}L$.

Step 2: $D_v f = \langle v, \nabla f\rangle$ almost everywhere. Let φ be C^1 with compact support. By translation invariance,

$$\int \frac{f(x + tv) - f(x)}{t}\varphi(x)\, dx = -\int f(x)\frac{\varphi(x) - \varphi(x - tv)}{t}\, dx.$$

Let $t = 1/j \to 0$. On the left the integrands converge almost everywhere to $D_v f\, \varphi$ and are bounded by $L|\varphi|$; on the right they converge to $f\, D_v\varphi = f\langle v, \nabla\varphi\rangle$ and are bounded by a constant times the indicator of a compact set, by the mean value inequality and the continuity of f. By dominated convergence, $\int D_v f\, \varphi = -\int f\langle v, \nabla\varphi\rangle = -\sum_i v_i \int f\, \partial_i\varphi = \sum_i v_i \int D_{e_i} f\, \varphi$, the last equality being the first one for $v = e_i$. So $\int (D_v f - \langle v, \nabla f\rangle)\varphi = 0$ for all φ, and Lemma 28.19.1 applies.

Step 3: differentiability. Let (v_k) be a dense sequence in the unit sphere, and let A be the set of points where ∇f and all $D_{v_k} f$ exist and $D_{v_k} f = \langle v_k, \nabla f\rangle$; its complement is a countable union of null sets. Fix $x \in A$, and for a unit vector v and $t \neq 0$ put $Q(v,t) = (f(x + tv) - f(x))/t - \langle v, \nabla f(x)\rangle$. Then $|Q(v,t) - Q(v',t)| \le (L + \sqrt{n}L)|v - v'|$. Given $\varepsilon > 0$, by compactness of the sphere there is N such that every unit vector is within $\varepsilon/(2(1 + \sqrt{n})L)$ of some v_k with $k \le N$, and there is $\delta > 0$ with $|Q(v_k,t)| < \varepsilon/2$ for $0 < |t| < \delta$ and $k \le N$. Then $|Q(v,t)| < \varepsilon$ for all unit vectors v and $0 < |t| < \delta$, that is, $|f(x + h) - f(x) - \langle \nabla f(x), h\rangle| \le \varepsilon|h|$ for $|h| < \delta$. So f is differentiable at x, with derivative $h \mapsto \langle \nabla f(x), h\rangle$. □

Counterexample 28.19.3. 1. Continuity is not enough: the Takagi function (Theorem 27.9.8) is continuous and differentiable nowhere, so it is not Lipschitz on any interval.

2. The exceptional null set can be dense. Let $q_1, q_2, \dots$ be an enumeration of $\mathbb{Q}$ and $f(x) = \sum_j 2^{-j}|x - q_j|$, a 1-Lipschitz function on $\mathbb{R}$. For $h > 0$,

$$\frac{f(q_k + h) - f(q_k)}{h} - \frac{f(q_k) - f(q_k - h)}{h} = \sum_j 2^{-j} \frac{|q_k - q_j + h| + |q_k - q_j - h| - 2|q_k - q_j|}{h} \geq 2^{1-k},$$

since every term is ≥ 0 by the triangle inequality and the term $j = k$ is 2^{1-k}. If f were differentiable at q_k the left side would tend to 0; so f is differentiable at no rational point.

3. Existence of all directional derivatives at a point does not imply differentiability there, even for Lipschitz functions: $f(x, y) = x^2 y/(x^2 + y^2)$, $f(0, 0) = 0$, is Lipschitz, has $D_v f(0) = f(v)$ for every unit vector v, and $v \mapsto f(v)$ is not linear. Step 3 of the proof is where the Lipschitz condition turns directional derivatives into a derivative.

28.20 The area formula

For a linear map $T\colon \mathbb{R}^n \to \mathbb{R}^n$, $\lambda^n(T(A)) = |\det T|\lambda^n(A)$. For a linear map $L\colon \mathbb{R}^k \to \mathbb{R}^m$ with $k \leq m$ the image of a cube is a k-dimensional parallelepiped in $\mathbb{R}^m$, and its k-dimensional volume is measured by $\mathcal{H}^k$. The factor replacing $|\det T|$ is the Jacobian of L.

Definition 28.20.1. The *Jacobian* of a linear map $L\colon \mathbb{R}^k \to \mathbb{R}^m$, $k \leq m$, is $JL = \sqrt{\det(L^T L)}$. For a map f differentiable at x, $Jf(x) = J(Df(x))$.

Lemma 28.20.2. *Let $L\colon \mathbb{R}^k \to \mathbb{R}^m$ be linear, $k \leq m$.*

1. *$(JL)^2$ is the sum of the squares of the $k \times k$ minors of the matrix of L, and $JL = 0$ if and only if L is not injective. For $k = m$, $JL = |\det L|$.*

2. *If L is injective, $L = O \circ S$ with $S = (L^T L)^{1/2}$ positive definite symmetric on $\mathbb{R}^k$, $\det S = JL$, and $O\colon \mathbb{R}^k \to \mathbb{R}^m$ an isometry onto $L(\mathbb{R}^k)$.*

3. *$\mathcal{H}^k(L(A)) = JL\,\lambda^k(A)$ for every Lebesgue measurable $A \subseteq \mathbb{R}^k$.*

Proof. (1) By Cauchy–Binet (Proposition 12.3.4(2)) applied to L^T and L, $\det(L^T L) = \sum_S \det(L_S)^2$, where L_S is the $k \times k$ submatrix with rows S. By Proposition 12.3.4(3), some minor is nonzero if and only if L has rank k. For $k = m$, $\det(L^T L) = (\det L)^2$.

(2) $L^T L$ is symmetric with $\langle L^T L v, v\rangle = |Lv|^2 > 0$ for $v \neq 0$, so by the spectral theorem (Theorem 11.10.6) it has a positive definite square root S, with $\det S = \sqrt{\det L^T L}$. Then $O = LS^{-1}$ satisfies $O^T O = S^{-1} L^T L S^{-1} = I$, so $|Ov| = |v|$, and $O(\mathbb{R}^k) = L(\mathbb{R}^k)$.

(3) If L is not injective, $L(\mathbb{R}^k)$ lies in a linear subspace W of dimension $k - 1$; an isometry $\mathbb{R}^{k-1} \to W$ and Theorem 28.17.5 give $\mathcal{H}^{k-1}(W \cap B) < \infty$ for every ball B, so $\mathcal{H}^k(W) = 0$ by Proposition 28.17.3(4), and both sides vanish. If L is injective, O is an isometry from $\mathbb{R}^k$ onto $L(\mathbb{R}^k)$, which preserves $\mathcal{H}^k$, so $\mathcal{H}^k(L(A)) = \mathcal{H}^k(S(A)) = \lambda^k(S(A)) = |\det S|\lambda^k(A)$ by Theorem 28.17.5 and Lemma 28.11.1; for Lebesgue measurable A write $A = B \cup N$ with B Borel and N contained in a Borel null set, which S maps to a null set. □

So JL is the k-dimensional volume of the parallelepiped spanned by $Le_1, \dots, Le_k$, the image of the unit cube. For a curve, $J\gamma(t) = |\gamma'(t)|$; for a parametrised surface $x(u, v)$ in $\mathbb{R}^3$, $Jx = |x_u \times x_v|$, since the three 2×2 minors of Dx are the components of $x_u \times x_v$ up to sign.

Theorem 28.20.3 (Area formula). *Let $U \subseteq \mathbb{R}^k$ be open and $f\colon U \to \mathbb{R}^m$ an injective C^1 map whose differential $Df(x)$ is injective at every point. Then for every Lebesgue measurable $A \subseteq U$ the set $f(A)$ is $\mathcal{H}^k$-measurable, and*

$$\mathcal{H}^k(f(A)) = \int_A Jf \, d\lambda^k.$$

Consequently $\int_{f(U)} g \, d\mathcal{H}^k = \int_U g(f(x))\, Jf(x)\, d\lambda^k(x)$ for every Borel function $g \geq 0$ on $\mathbb{R}^m$.

Proof. For an injective linear $L\colon \mathbb{R}^k \to \mathbb{R}^m$ let $m(L) = \min_{|v|=1} |Lv| > 0$. Fix $t > 1$.

Step 1: a decomposition of U. Call a pair (B, L) of an open ball $B \subseteq U$ with rational centre and radius and an injective linear map L with rational matrix *good* if, for all $x, y \in B$,

$$t^{-1}|L(x-y)| \leq |f(x)-f(y)| \leq t|L(x-y)| \qquad \text{and} \qquad t^{-k}JL \leq Jf(x) \leq t^k JL. \tag{28.4}$$

Every $x_0 \in U$ lies in the ball of some good pair. Indeed, let $\mu_0 = m(Df(x_0)) > 0$ and $\eta = (1-t^{-1})\mu_0/2$. Since $|m(L) - m(L')| \leq \|L - L'\|$, J is continuous, and $Jf(x_0) > 0$, there is L with rational matrix such that $\|Df(x_0) - L\| < \min(\eta, \mu_0)/2$ and $t^{-k}JL < Jf(x_0) < t^k JL$; then $m(L) \geq \mu_0/2$, so $\eta \leq (1-t^{-1})m(L)$. By continuity of Df and of J there is a rational ball $B \ni x_0$ on which $\|Df - L\| \leq \eta$ and still $t^{-k}JL \leq Jf \leq t^k JL$. For $x, y \in B$, by the mean value inequality (Proposition 27.10.3(4)) applied to $f - L$ on the convex set B, $|f(x)-f(y)-L(x-y)| \leq \eta|x-y| \leq (1-t^{-1})|L(x-y)|$, which gives $t^{-1}|L(x-y)| \leq |f(x)-f(y)| \leq (2-t^{-1})|L(x-y)| \leq t|L(x-y)|$. Enumerate the countably many good pairs as (B_j, L_j), and let $E_j = B_j \setminus \bigcup_{i<j} B_i$; these are disjoint Borel sets covering U.

Step 2: estimates on one piece. Let $A \subseteq E_j$ be Lebesgue measurable. By (28.4) the map $L_j(x) \mapsto f(x)$, from $L_j(B_j)$ to $f(B_j)$, is t-Lipschitz, and so is its inverse. By Proposition 28.17.3(3) and Lemma 28.20.2(3),

$$t^{-k}JL_j\, \lambda^k(A) \leq \mathcal{H}^k(f(A)) \leq t^k JL_j\, \lambda^k(A), \qquad t^{-k}JL_j\, \lambda^k(A) \leq \int_A Jf \leq t^k JL_j\, \lambda^k(A),$$

the second pair by (28.4). Hence $t^{-2k}\int_A Jf \leq \mathcal{H}^k(f(A)) \leq t^{2k}\int_A Jf$; here $\mathcal{H}^k$ is the outer measure.

Step 3: measurability. A Lebesgue measurable $A \subseteq U$ is $K \cup N$ with K a countable union of compact sets and N null (Theorem 28.3.4). Then $f(K)$ is a countable union of compact sets, hence Borel, and $\mathcal{H}^k(f(N)) \leq \sum_j \mathcal{H}^k(f(N \cap E_j)) = 0$ by Step 2. So $f(A)$ differs from a Borel set by an $\mathcal{H}^k$-null set, and it is $\mathcal{H}^k$-measurable (Theorem 28.3.2).

Step 4. For measurable $A \subseteq U$, the sets $f(A \cap E_j)$ are measurable and disjoint, since f is injective. Summing Step 2 over j, $t^{-2k}\int_A Jf \leq \mathcal{H}^k(f(A)) \leq t^{2k}\int_A Jf$, and $t > 1$ was arbitrary. For a Borel set $G \subseteq \mathbb{R}^m$, applying this to $A = f^{-1}(G)$ gives the integral formula for $g = \mathbf{1}_G$; it follows for simple functions by linearity, and for Borel $g \geq 0$ by monotone convergence (Theorem 28.4.3). □

For $k = m$ the area formula is the change of variables formula (Theorem 28.11.2), with $\mathcal{H}^m = \lambda^m$. The proof is the same idea: on small pieces f is almost linear, and linear maps multiply measure by the Jacobian.

Example 28.20.4.

1. *Length of curves.* For an injective C^1 curve $\gamma\colon (a,b) \to \mathbb{R}^m$ with $\gamma' \neq 0$, $\mathcal{H}^1(\gamma((a,b))) = \int_a^b |\gamma'(t)|\, dt$. So the length of a curve, defined by parametrisations, is the one-dimensional Hausdorff measure of its image, which depends only on the set.

2. *Area of graphs.* For $h\colon U \to \mathbb{R}$ of class C^1, $U \subseteq \mathbb{R}^k$ open, the graph map $f(x) = (x, h(x))$ is injective with injective differential, and $Jf = \sqrt{\det(I + \nabla h\, \nabla h^T)} = \sqrt{1 + |\nabla h|^2}$, since $I + ww^T$ is the identity on $w^\perp$ and multiplies w by $1 + |w|^2$. So the graph has area $\int_U \sqrt{1 + |\nabla h|^2}\, d\lambda^k$.

3. *The area of the sphere.* The upper hemisphere of S^2 is the graph of $h(x) = \sqrt{1-|x|^2}$ over the open unit disc, with $|\nabla h|^2 = |x|^2/(1-|x|^2)$ and $Jf = (1-|x|^2)^{-1/2}$. In polar coordinates (Example 28.11.3), $\mathcal{H}^2 = \int_0^{2\pi}\int_0^1 r(1-r^2)^{-1/2}\,dr\,d\theta = 2\pi$. The equator has finite $\mathcal{H}^1$-measure by (1), so it is $\mathcal{H}^2$-null (Proposition 28.17.3(4)), and $\mathcal{H}^2(S^2) = 4\pi$.

Counterexample 28.20.5. Injectivity is needed: for $f(t) = (\cos t, \sin t)$ on $(0, 4\pi)$, $\int Jf = 4\pi$, while the image, the circle minus one point, has $\mathcal{H}^1$-measure 2π. The integral counts the points of the image with multiplicity: in general $\int_A Jf = \int_{\mathbb{R}^m} \#(A \cap f^{-1}(y))\,d\mathcal{H}^k(y)$ (Remark 28.20.9).

The area formula also computes the area of surfaces of revolution, and gives the second theorem of Pappus. As in Proposition 28.11.7, the axis is the z-axis and (r, z) are the distance from the axis and the height.

Proposition 28.20.6 (Pappus–Guldin theorem for areas)**.** *Let $\gamma = (\rho, \zeta)\colon [a,b] \to \mathbb{R}^2$ be a C^1 curve with $\rho \geq 0$ on $[a,b]$ and $\rho > 0$ on (a,b), injective and regular on (a,b), and let $\Sigma = \{(\rho(t)\cos\theta, \rho(t)\sin\theta, \zeta(t)) : t \in [a,b], \theta \in \mathbb{R}\}$ be the surface obtained by rotating it around the z-axis. Then*

$$\mathcal{H}^2(\Sigma) = 2\pi \int_\gamma r\,ds = 2\pi \bar{r}\, L(\gamma),$$

where $\int_\gamma r\,ds = \int_a^b \rho(t)|\gamma'(t)|\,dt$ is a line integral of the first kind (Definition 27.11.9) and $\bar{r} = L(\gamma)^{-1}\int_\gamma r\,ds$ is the distance of the centroid of the curve from the axis.

Proof. Let $\Phi(t,\theta) = (\rho(t)\cos\theta, \rho(t)\sin\theta, \zeta(t))$ on $U = (a,b)\times(0,2\pi)$. It is injective: $\rho(t) > 0$ and $\zeta(t)$ are recovered from $\Phi(t,\theta)$ as the distance from the axis and the height, which determine t because γ is injective on (a,b), and then $\theta \in (0,2\pi)$ is determined. Its partial derivatives $\Phi_t = (\rho'\cos\theta, \rho'\sin\theta, \zeta')$ and $\Phi_\theta = (-\rho\sin\theta, \rho\cos\theta, 0)$ are orthogonal, with $|\Phi_t| = |\gamma'(t)|$ and $|\Phi_\theta| = \rho(t)$. So $D\Phi^T D\Phi = \operatorname{diag}(|\gamma'|^2, \rho^2)$, $J\Phi = \rho|\gamma'| > 0$ (Definition 28.20.1), and $D\Phi$ is injective. By the area formula (Theorem 28.20.3) and Tonelli's theorem, $\mathcal{H}^2(\Phi(U)) = \int_0^{2\pi}\int_a^b \rho(t)|\gamma'(t)|\,dt\,d\theta = 2\pi\int_\gamma r\,ds$. The rest of Σ is contained in the meridian $\Phi([a,b]\times\{0\})$ and the two circles (or points) $\Phi(\{a\}\times\mathbb{R})$ and $\Phi(\{b\}\times\mathbb{R})$. These are images of compact intervals under C^1 maps, which are Lipschitz by the mean value inequality, so they have finite $\mathcal{H}^1$-measure by Proposition 28.17.3(3) and are $\mathcal{H}^2$-null by part (4) of the same proposition. □

Example 28.20.7. 1. *The sphere.* The half circle $\gamma(t) = (R\sin t, -R\cos t)$, $t \in [0,\pi]$, has $\int_\gamma r\,ds = \int_0^\pi R\sin t \cdot R\,dt = 2R^2$, so the sphere of radius R has area $4\pi R^2$; the centroid of the half circle is at distance $2R/\pi$ from the axis, as in Example 27.11.11(1).

2. *Archimedes' hat-box theorem.* The part of that sphere between the heights $z = c$ and $z = c+h$, with $-R \leq c < c+h \leq R$, comes from t with $-R\cos t \in [c, c+h]$, and its area is $2\pi\int R\sin t \cdot R\,dt = 2\pi R\big[-R\cos t\big] = 2\pi R h$. So the area of a spherical zone depends only on its height, and equals the area of the corresponding zone of the circumscribed cylinder: projecting the sphere horizontally onto the cylinder preserves areas. This is the principle behind Lambert's cylindrical equal-area map.

3. *The torus.* The circle of radius a centred at distance $c > a$ from the axis has centroid at its centre, so the torus has area $2\pi c \cdot 2\pi a = 4\pi^2 ac$. (The parametrisation $t \mapsto (c + a\cos t, a\sin t)$, $t \in [0, 2\pi]$, is injective on $(0,2\pi)$, as the proposition requires.)

Counterexample 28.20.8. *Torricelli's trumpet*, also called Gabriel's horn: rotate the graph of $1/x$, $x \geq 1$, around the x-axis. By the disc method (Proposition 28.11.7(1), and monotone

convergence as the length tends to infinity) the solid has volume $\pi \int_1^\infty x^{-2}\,dx = \pi$. By Proposition 28.20.6, applied to $\gamma(x) = (1/x, x)$ on $[1, T]$ and letting $T \to \infty$, its surface has area

$$2\pi \int_1^\infty \frac{1}{x}\sqrt{1 + x^{-4}}\,dx \geq 2\pi \int_1^\infty \frac{dx}{x} = \infty.$$

So the trumpet can be filled with a finite amount of paint, but its inner surface cannot be painted. Torricelli's discovery (1643) of a solid of infinite extent and finite volume was a surprise to his contemporaries. The paradox disappears once one notes that area and volume scale differently: a layer of paint of fixed thickness does not fit into the narrow end of the trumpet.

Remark 28.20.9. *The general area and coarea formulas.* By Rademacher's theorem a Lipschitz map $f : \mathbb{R}^k \to \mathbb{R}^m$ has a Jacobian almost everywhere, and the area formula holds in the generality

$$\int_A Jf\,d\lambda^k = \int_{\mathbb{R}^m} \#\big(A \cap f^{-1}(y)\big)\,d\mathcal{H}^k(y) \qquad (k \leq m),$$

for Lebesgue measurable A, where # is the number of points [EG92, Section 3.3], [Fed69, Section 3.2]. For $k \geq m$ there is a dual statement, the *coarea formula*: with $Jf = \sqrt{\det(Df\,Df^T)}$,

$$\int_A Jf\,d\lambda^k = \int_{\mathbb{R}^m} \mathcal{H}^{k-m}\big(A \cap f^{-1}(y)\big)\,d\lambda^m(y) \qquad (k \geq m),$$

which slices A by the level sets of f instead of parametrising it [EG92, Section 3.4]. For $f(x) = |x|$ on $\mathbb{R}^n$, $Jf = |\nabla f| = 1$ away from 0, and the coarea formula gives integration in spherical shells, $\int_{\mathbb{R}^n} g\,d\lambda = \int_0^\infty \big(\int_{|x|=r} g\,d\mathcal{H}^{n-1}\big)dr$; for a C^1 function u it gives $\int |\nabla u| = \int_{\mathbb{R}} \mathcal{H}^{n-1}(\{u = s\})\,ds$, the starting point of the isoperimetric and Sobolev inequalities. A set is *k-rectifiable* if it is covered, up to an $\mathcal{H}^k$-null set, by countably many Lipschitz images of subsets of $\mathbb{R}^k$; these sets, which include all k-dimensional submanifolds, are the objects on which geometric measure theory does calculus, and the area formula is the bridge between them and Lebesgue measure.

28.21 The coarea formula

The area formula measures a set by parametrising it. The coarea formula measures it by slicing. The model is Fubini's theorem: the volume of $A \subseteq \mathbb{R}^n$ is the integral of the $(n-1)$-dimensional volumes of the slices $A \cap \{x_n = t\}$. If the slices are the level sets $f^{-1}(t)$ of a function f which are not parallel hyperplanes, the slab between the levels t and $t + dt$ has thickness about $dt/|\nabla f|$: where the levels are crowded, the slab is thin. So the volume of the slab is about $\mathcal{H}^{n-1}(\text{slice})\,dt/|\nabla f|$, and integrating $|\nabla f|$ instead of 1 compensates exactly:

$$\int_A |\nabla f|\,d\lambda^n = \int_{\mathbb{R}} \mathcal{H}^{n-1}\big(A \cap f^{-1}(t)\big)\,dt.$$

We prove this for C^1 functions without critical points; the general statement is in Remark 28.20.9. Throughout, $n \geq 2$.

Lemma 28.21.1. *Let $v_1, \dots, v_{n-1} \in \mathbb{R}^n$ be linearly independent, V the $n \times (n-1)$ matrix with these columns, ν a unit vector orthogonal to all v_i, and $w \in \mathbb{R}^n$. Then*

$$|\det(v_1, \dots, v_{n-1}, w)| = JV \cdot |\langle w, \nu\rangle|.$$

In words: the volume of a parallelepiped is the $(n-1)$-dimensional volume of its base times its height. Recall that $JV = \sqrt{\det(V^TV)}$ is the $(n-1)$-dimensional volume of the base (Lemma 28.20.2).

Proof. Write $w = u + \langle w, v\rangle v$ with u in the span of the v_i. The determinant is linear in the last column and vanishes when the columns are dependent, so $\det(V, w) = \langle w, v\rangle \det(V, v)$. For the matrix $M = (V, v)$, M^TM is block diagonal with blocks V^TV and $\langle v, v\rangle = 1$, because $V^Tv = 0$. Hence $(\det M)^2 = \det(M^TM) = \det(V^TV) = (JV)^2$. □

Theorem 28.21.2 (Coarea formula)**.** *Let $U \subseteq \mathbb{R}^n$ be open and $f\colon U \to \mathbb{R}$ of class C^1 with $\nabla f(x) \neq 0$ for all $x \in U$. For every Borel set $A \subseteq U$ the function $t \mapsto \mathcal{H}^{n-1}(A \cap f^{-1}(t))$ is Lebesgue measurable, and*

$$\int_A |\nabla f|\, d\lambda^n = \int_{\mathbb{R}} \mathcal{H}^{n-1}\big(A \cap f^{-1}(t)\big)\, dt.$$

More generally, for every Borel function $g\colon U \to [0,\infty]$,

$$\int_U g\,|\nabla f|\, d\lambda^n = \int_{\mathbb{R}} \Big(\int_{f^{-1}(t)} g\, d\mathcal{H}^{n-1} \Big) dt. \tag{28.5}$$

Proof. Step 1: local coordinates adapted to f. Let $x_0 \in U$. Some partial derivative $\partial_i f(x_0)$ is nonzero. A permutation of the coordinates is an isometry of $\mathbb{R}^n$, so it preserves λ^n (Lemma 28.11.1), $\mathcal{H}^{n-1}$ and $|\nabla f|$; so we may assume $\partial_n f(x_0) \neq 0$. The map $\psi(x) = (x_1, \dots, x_{n-1}, f(x))$ has $\det D\psi(x_0) = \partial_n f(x_0) \neq 0$. By the inverse function theorem (Theorem 27.12.2) there are open sets $V \ni x_0$ and W such that $\psi\colon V \to W$ is a C^1-diffeomorphism. Let $\phi = \psi^{-1}\colon W \to V$, and write points of $W \subseteq \mathbb{R}^{n-1} \times \mathbb{R}$ as (y, t). Since $\psi(\phi(y,t)) = (y,t)$,

$$f(\phi(y,t)) = t \qquad \text{for } (y,t) \in W.$$

For fixed t let $W_t = \{y : (y,t) \in W\}$, open in $\mathbb{R}^{n-1}$, and $\phi_t = \phi(-,t)\colon W_t \to \mathbb{R}^n$. It is injective and C^1, and $D\phi_t$ is injective, as its columns are the first $n-1$ columns of the invertible matrix $D\phi$. Its image is $V \cap f^{-1}(t)$: a point $x \in V$ has $f(x) = t$ if and only if $\psi(x) = (y,t)$ for some y.

Step 2: the Jacobian identity. We claim $|\det D\phi(y,t)|\,|\nabla f(\phi(y,t))| = J\phi_t(y)$. Differentiating $f(\phi(y,t)) = t$ with the chain rule gives $\langle \nabla f, \partial_{y_i}\phi\rangle = 0$ for $i < n$ and $\langle \nabla f, \partial_t \phi\rangle = 1$, all evaluated at $\phi(y,t)$ resp. (y,t). So $v = \nabla f/|\nabla f|$ is a unit vector orthogonal to the columns $\partial_{y_i}\phi$ of $D\phi_t$, and Lemma 28.21.1 with $w = \partial_t\phi$ gives

$$|\det D\phi| = J\phi_t \cdot |\langle \partial_t\phi, v\rangle| = \frac{J\phi_t}{|\nabla f|}.$$

Step 3: the formula on V. Let $A \subseteq V$ be Borel, and $h = \mathbf{1}_A \circ \phi$, a Borel function on W. By the change of variables formula (Theorem 28.11.2) for $\phi\colon W \to V$ and Step 2,

$$\int_A |\nabla f|\, d\lambda^n = \int_W h(y,t)\,|\nabla f(\phi(y,t))|\,|\det D\phi(y,t)|\, d\lambda^n(y,t) = \int_W h(y,t)\, J\phi_t(y)\, d\lambda^n(y,t).$$

The integrand, extended by 0 outside W, is a nonnegative Borel function on $\mathbb{R}^{n-1} \times \mathbb{R}$. By Tonelli's theorem (Theorem 28.10.3 and Remark 28.10.5) the function $t \mapsto \int_{W_t} h(y,t) J\phi_t(y)\, dy$ is measurable and the last integral equals $\int_{\mathbb{R}} \big(\int_{W_t} h(y,t) J\phi_t(y)\, dy \big) dt$. By the area formula (Theorem 28.20.3) for ϕ_t and the Borel set $B_t = \{y \in W_t : \phi(y,t) \in A\}$, whose image is $A \cap f^{-1}(t)$ by Step 1,

$$\int_{W_t} h(y,t) J\phi_t(y)\, dy = \int_{B_t} J\phi_t\, d\lambda^{n-1} = \mathcal{H}^{n-1}\big(A \cap f^{-1}(t)\big).$$

This proves the theorem for Borel subsets of V.

Step 4: globalisation. U is a countable union of compact sets, each covered by finitely many of the open sets V of Step 1; so $U = \bigcup_j V_j$ for countably many such sets. Let $E_j = V_j \setminus \bigcup_{i<j} V_i$, disjoint Borel sets covering U. For a Borel set $A \subseteq U$, apply Step 3 to $A \cap E_j \subseteq V_j$ and sum over j. On the left, $\sum_j \int_{A\cap E_j} |\nabla f| = \int_A |\nabla f|$ by monotone convergence. On the right, for every t the sets $A \cap E_j \cap f^{-1}(t)$ are disjoint Borel sets with union $A \cap f^{-1}(t)$, and $\mathcal{H}^{n-1}$ is a measure on Borel sets (Proposition 28.17.3), so $\mathcal{H}^{n-1}(A \cap f^{-1}(t)) = \sum_j \mathcal{H}^{n-1}(A \cap E_j \cap f^{-1}(t))$, a sum of measurable functions of t; integrate with monotone convergence (Theorem 28.4.3). Finally, (28.5) is the first formula for $g = \mathbf{1}_A$; it follows for simple Borel functions by linearity and for all Borel $g \geq 0$ by monotone convergence, applied on both sides. □

For $f(x) = x_n$ the coarea formula is Fubini's theorem. Its most important special case is integration in polar coordinates.

Corollary 28.21.3 (Polar coordinates)**.** *Let $S^{n-1} = \{x \in \mathbb{R}^n : |x| = 1\}$ and $\omega_n = \lambda^n(B(0,1))$. Then $\mathcal{H}^{n-1}(S^{n-1}) = n\omega_n$, and for every Borel function $g\colon \mathbb{R}^n \to [0,\infty]$,*

$$\int_{\mathbb{R}^n} g\, d\lambda^n = \int_0^\infty \Big(\int_{|x|=r} g\, d\mathcal{H}^{n-1}\Big) dr = \int_0^\infty r^{n-1} \Big(\int_{S^{n-1}} g(r\theta)\, d\mathcal{H}^{n-1}(\theta)\Big) dr.$$

In particular, if $g(x) = h(|x|)$ is radial, $\int_{\mathbb{R}^n} g\, d\lambda^n = n\omega_n \int_0^\infty h(r) r^{n-1}\, dr$.

Proof. Apply Theorem 28.21.2 to $f(x) = |x|$ on $U = \mathbb{R}^n \setminus \{0\}$. Here $\nabla f(x) = x/|x|$, so $|\nabla f| = 1$, and the point 0 is a null set. This gives the first equality. For the second, $\theta \mapsto r\theta$ is a similarity with ratio r from S^{n-1} onto the sphere of radius r, so $\mathcal{H}^{n-1}(\{|x| = r\} \cap G) = r^{n-1}\mathcal{H}^{n-1}(S^{n-1} \cap r^{-1}G)$ for Borel sets G (Proposition 28.17.3(3)), which is the second equality for $g = \mathbf{1}_G$; pass to simple functions and to limits by monotone convergence. For $g = \mathbf{1}_{B(0,1)}$ we get $\omega_n = \mathcal{H}^{n-1}(S^{n-1}) \int_0^1 r^{n-1}\, dr = \mathcal{H}^{n-1}(S^{n-1})/n$. □

Example 28.21.4. 1. *Spheres.* $\mathcal{H}^1(S^1) = 2\omega_2 = 2\pi$ and $\mathcal{H}^2(S^2) = 3\omega_3 = 3 \cdot \frac{4}{3}\pi = 4\pi$, in agreement with Example 28.20.4. The formula $\mathcal{H}^{n-1}(S^{n-1}) = n\omega_n$ says that the volume of the ball, $\omega_n R^n$, has derivative $n\omega_n R^{n-1}$ in R equal to the area of the sphere of radius R: adding a thin shell of thickness dR adds volume (area)$\cdot dR$.

2. *Integrability of powers.* For $a \in \mathbb{R}$, $\int_{|x|<1} |x|^{-a}\, dx = n\omega_n \int_0^1 r^{n-1-a}\, dr$ is finite if and only if $a < n$, and $\int_{|x|>1} |x|^{-a}\, dx = n\omega_n \int_1^\infty r^{n-1-a}\, dr$ is finite if and only if $a > n$. So $|x|^{-a}$ is never integrable on all of $\mathbb{R}^n$, and the borderline exponent is the dimension, as for $\sum_{k\in\mathbb{Z}^n\setminus 0} |k|^{-a}$.

3. *The volume of balls.* By Fubini's theorem and Example 28.11.3, $\int_{\mathbb{R}^n} e^{-|x|^2} dx = (\int_{\mathbb{R}} e^{-t^2} dt)^n = \pi^{n/2}$. By the corollary and the substitution $u = r^2$ it also equals $n\omega_n \int_0^\infty e^{-r^2} r^{n-1}\, dr = \frac{n\omega_n}{2} \int_0^\infty e^{-u} u^{n/2-1}\, du = \frac{n\omega_n}{2}\Gamma(\frac{n}{2})$. Hence $\omega_n = \pi^{n/2}/\Gamma(\frac{n}{2}+1)$, which solves Exercise 28.23.7: $\omega_1 = 2$, $\omega_2 = \pi$, $\omega_3 = \frac{4}{3}\pi$, $\omega_4 = \frac{\pi^2}{2}$, and $\omega_n \to 0$ very fast as $n \to \infty$.

Remark 28.21.5. 1. *Critical points.* For a Lipschitz f the coarea formula holds without excluding critical points [EG92, Section 3.4]. On the critical set $Z = \{\nabla f = 0\}$ the left side vanishes, so the formula contains the statement that $\mathcal{H}^{n-1}(Z \cap f^{-1}(t)) = 0$ for almost every t. This is remarkable because the set of critical values $f(Z)$ can have positive measure: Sard's theorem, which says it is null, needs f of class C^n, and Whitney constructed a C^1 function on $\mathbb{R}^2$ that is not constant on a connected arc of critical points [Whi35]; its critical values fill an interval, yet each level set meets Z in an $\mathcal{H}^1$-null set.

2. *Isoperimetry and Sobolev inequalities.* For $u \in C_c^1(\mathbb{R}^n)$ the coarea formula reads $\int |\nabla u| = \int_{\mathbb{R}} \mathcal{H}^{n-1}(\{u = t\})\,dt$ (in the general version), and $\{u = t\}$ is, for almost every $t > 0$, the boundary of $\{u > t\}$. The *isoperimetric inequality* $\mathcal{H}^{n-1}(\partial E) \geq n\omega_n^{1/n}\lambda^n(E)^{(n-1)/n}$, with equality for balls, then gives the *Sobolev inequality* $\|u\|_{n/(n-1)} \leq (n\omega_n^{1/n})^{-1}\|\nabla u\|_1$ with its best constant; conversely, the Sobolev inequality applied to smoothed indicator functions gives back the isoperimetric inequality. This equivalence between a geometric and an analytic inequality is due to Federer and Fleming and to Maz'ya [FF60].

28.22 Densities and rectifiability

By the Lebesgue density theorem (Corollary 28.9.5) a measurable set $A \subseteq \mathbb{R}^n$ fills almost all of every small ball centred at almost every one of its points. For a set of dimension $s < n$ the analogous question is whether $\mathcal{H}^s(A \cap \overline{B}(x,r))$ is comparable to $\alpha(s)(2r)^s$, the s-dimensional "volume" of a ball of radius r. For smooth curves and surfaces the answer is yes, with ratio tending to 1; for the Cantor set the ratio oscillates forever. This difference turns out to be the difference between the sets on which one can do calculus, the rectifiable ones, and the others. Throughout, X is a metric space and $\overline{B}(x,r) = \{y : d(x,y) \leq r\}$.

Definition 28.22.1. For $A \subseteq X$, $s > 0$ and $x \in X$, the *upper* and *lower s-dimensional densities* of A at x are

$$\Theta^{*s}(A,x) = \limsup_{r\to 0} \frac{\mathcal{H}^s(A \cap \overline{B}(x,r))}{\alpha(s)(2r)^s}, \qquad \Theta^s_*(A,x) = \liminf_{r\to 0} \frac{\mathcal{H}^s(A \cap \overline{B}(x,r))}{\alpha(s)(2r)^s}.$$

If they are equal, the common value is the *density* $\Theta^s(A,x)$.

The normalisation is chosen so that flat pieces have density 1. For $A \subseteq \mathbb{R}^n$ Lebesgue measurable and $s = n$, $\mathcal{H}^n = \lambda^n$ and $\alpha(n)(2r)^n = \lambda^n(\overline{B}(x,r))$, so by the density theorem $\Theta^n(A,x) = 1$ for almost every $x \in A$ and $\Theta^n(A,x) = 0$ for almost every $x \notin A$ (spheres are null, so closed and open balls give the same ratios).

Example 28.22.2. *Curves have density* 1. Let $\gamma\colon (a,b) \to \mathbb{R}^m$ be an injective C^1 map with $\gamma' \neq 0$ which is a homeomorphism onto its image Γ. Then $\Theta^1(\Gamma,x) = 1$ for every $x \in \Gamma$. Let $x = \gamma(t_0)$, $c = |\gamma'(t_0)| > 0$, and $0 < \varepsilon < 1$. Choose $\delta > 0$ with $[t_0 - \delta, t_0 + \delta] \subseteq (a,b)$ and $|\gamma'(t) - \gamma'(t_0)| \leq \varepsilon c$ there. By the mean value inequality, applied to $\gamma(t) - \gamma'(t_0)(t - t_0)$,

$$(1-\varepsilon)c|t - t_0| \leq |\gamma(t) - x| \leq (1+\varepsilon)c|t - t_0| \qquad (|t - t_0| \leq \delta),$$

and $(1-\varepsilon)c \leq |\gamma'(t)| \leq (1+\varepsilon)c$ there. Since γ^{-1} is continuous at x, there is $r_0 \in (0, (1-\varepsilon)c\delta]$ such that $|\gamma(t) - x| \leq r_0$ implies $|t - t_0| \leq \delta$. For $r < r_0$ the set $I_r = \{t : |\gamma(t) - x| \leq r\}$ therefore satisfies

$$\left[t_0 - \tfrac{r}{(1+\varepsilon)c}, t_0 + \tfrac{r}{(1+\varepsilon)c}\right] \subseteq I_r \subseteq \left[t_0 - \tfrac{r}{(1-\varepsilon)c}, t_0 + \tfrac{r}{(1-\varepsilon)c}\right].$$

By the area formula (Theorem 28.20.3), $\mathcal{H}^1(\Gamma \cap \overline{B}(x,r)) = \int_{I_r} |\gamma'|$ lies between $2r\frac{1-\varepsilon}{1+\varepsilon}$ and $2r\frac{1+\varepsilon}{1-\varepsilon}$. As $\alpha(1) = 1$ and ε was arbitrary, the ratio tends to 1. The homeomorphism condition matters: for a curve shaped like the digit 6, whose end $\gamma(t)$, $t \to b$, runs into an interior point x from one side, a small ball around x contains the arc of the curve through x, of length about $2r$, and the end arc, of length about r, and $\Theta^1(\Gamma,x) = \frac{3}{2}$.

Example 28.22.3. *The Cantor set has no density at* 0. Let C be the Cantor set, $s = \log 2/\log 3$, and $c = \mathcal{H}^s(C)$, so that $\alpha(s)/2 \leq c \leq \alpha(s)$ (Example 28.17.6). For $k \geq 0$, $C \cap [0, 3^{-k}] = 3^{-k}C$ (the piece C_w for $w = 1\cdots 1$ of length k, in the notation of Example 28.18.7), so $\mathcal{H}^s(C \cap [0,3^{-k}]) =$

$3^{-ks}c = 2^{-k}c$. Moreover C does not meet the gap $(3^{-k-1}, 2\cdot 3^{-k-1})$, so $C \cap [0, 2\cdot 3^{-k-1}]$ is $C \cap [0, 3^{-k-1}]$ plus the single point $2\cdot 3^{-k-1}$. Hence, with $r = 3^{-k}$ and $r = 2\cdot 3^{-k-1}$ respectively,

$$\frac{\mathcal{H}^s(C \cap \overline{B}(0, 3^{-k}))}{\alpha(s)(2\cdot 3^{-k})^s} = \frac{2^{-k}c}{\alpha(s)2^s 2^{-k}} = \frac{c}{\alpha(s)2^s}, \qquad \frac{\mathcal{H}^s(C \cap \overline{B}(0, 2\cdot 3^{-k-1}))}{\alpha(s)(4\cdot 3^{-k-1})^s} = \frac{2^{-k-1}c}{\alpha(s)4^s 2^{-k-1}} = \frac{c}{\alpha(s)4^s}.$$

So $\Theta^{*s}(C, 0) \geq c/(\alpha(s)2^s)$ and $\Theta^s_*(C, 0) \leq c/(\alpha(s)4^s)$, which is smaller by the factor $2^s \approx 1.55$; as $c > 0$, the density does not exist. The same computation works at the left endpoint $f_w(0)$ of every interval I_w: for $r < 3^{-|w|}$ the ball $\overline{B}(f_w(0), r)$ meets C in $f_w(C \cap [0, 3^{|w|}r])$, because C has a gap of length at least $3^{-|w|}$ to the left of I_w (Example 28.17.6(2)), and $\mathcal{H}^s$ scales by $3^{-|w|s}$ under f_w. These endpoints are dense in C.

For a general set we cannot expect the density to exist, but the upper density is bounded below almost everywhere, by a short covering argument that uses nothing but the definition of $\mathcal{H}^s$.

Theorem 28.22.4. *Let $A \subseteq X$ with $\mathcal{H}^s(A) < \infty$, $s > 0$. Then $\Theta^{*s}(A, x) \geq 2^{-s}$ for $\mathcal{H}^s$-almost every $x \in A$.*

Proof. For $0 < t < 2^{-s}$ and $k \geq 1$ let

$$A_{t,k} = \big\{x \in A : \mathcal{H}^s(A \cap \overline{B}(x, r)) \leq t\,\alpha(s)(2r)^s \text{ for all } 0 < r < 1/k\big\}.$$

A point $x \in A$ with $\Theta^{*s}(A, x) < 2^{-s}$ lies in some $A_{t,k}$ with t rational; so it suffices to show $\mathcal{H}^s(A_{t,k}) = 0$ for all t and k, by countable subadditivity.

Fix t, k, let $0 < \delta < 1/k$ and $\varepsilon > 0$, and choose a cover (C_i) of $A_{t,k}$ by sets of diameter at most δ with $\sum_i \alpha(s)(\operatorname{diam} C_i)^s \leq \mathcal{H}^s_\delta(A_{t,k}) + \varepsilon$. We may discard the C_i that do not meet $A_{t,k}$. For the others pick $x_i \in C_i \cap A_{t,k}$ and let $d_i = \operatorname{diam} C_i$. If $d_i > 0$, then $C_i \subseteq \overline{B}(x_i, d_i)$ with $d_i < 1/k$, so by the definition of $A_{t,k}$

$$\mathcal{H}^s(A_{t,k} \cap C_i) \leq \mathcal{H}^s(A \cap \overline{B}(x_i, d_i)) \leq t\,\alpha(s)(2d_i)^s = t2^s\,\alpha(s)d_i^s.$$

If $d_i = 0$, then C_i is a point and both sides are 0. Summing, and using countable subadditivity of $\mathcal{H}^s$,

$$\mathcal{H}^s(A_{t,k}) \leq \sum_i \mathcal{H}^s(A_{t,k} \cap C_i) \leq t2^s\big(\mathcal{H}^s_\delta(A_{t,k}) + \varepsilon\big) \leq t2^s\big(\mathcal{H}^s(A_{t,k}) + \varepsilon\big).$$

Let $\varepsilon \to 0$. Since $\mathcal{H}^s(A_{t,k}) \leq \mathcal{H}^s(A) < \infty$ and $t2^s < 1$, this forces $\mathcal{H}^s(A_{t,k}) = 0$. □

The bound 2^{-s} comes from the comparison $C_i \subseteq \overline{B}(x_i, \operatorname{diam} C_i)$, which loses a factor 2 in the radius. Inequalities in the other direction, bounding the upper density from above, need a different idea: instead of starting from an arbitrary cover and enclosing its sets in balls, one starts from balls on which the measure is large and extracts disjoint ones. This is a covering lemma of Vitali type, and it works in every metric space. For a closed ball $B = \overline{B}(x, r)$, given together with its centre and radius, write $\widehat{B} = \overline{B}(x, 5r)$.

Lemma 28.22.5 (5r-covering lemma)**.** *Let $\mathcal{F}$ be a family of closed balls $\overline{B}(x, r)$, $r > 0$, in a metric space, with $\sup\{r\} = R < \infty$. There is a subfamily $\mathcal{G}$ of pairwise disjoint balls such that every $B \in \mathcal{F}$ meets some $B' \in \mathcal{G}$ whose radius is at least half the radius of B; in particular $B \subseteq \widehat{B'}$.*

Proof. Let $\mathcal{F}_j$ be the set of balls in $\mathcal{F}$ with radius in $(2^{-j}R, 2^{1-j}R]$, $j \geq 1$. By Zorn's lemma choose a maximal pairwise disjoint subfamily $\mathcal{G}_1$ of $\mathcal{F}_1$ (the union of a chain of disjoint subfamilies is disjoint), and inductively a maximal pairwise disjoint subfamily $\mathcal{G}_j$ of the balls

in $\mathcal{F}_j$ that are disjoint from all balls of $\mathcal{G}_1 \cup \cdots \cup \mathcal{G}_{j-1}$. Let $\mathcal{G} = \bigcup_j \mathcal{G}_j$; it is pairwise disjoint. Let $B = \overline{B}(x,r) \in \mathcal{F}_j$. Either B meets a ball of some $\mathcal{G}_i$ with $i < j$, whose radius exceeds $2^{-i}R \geq 2^{1-j}R \geq r$; or it is disjoint from all of them, and then by maximality of $\mathcal{G}_j$ it meets a ball of $\mathcal{G}_j$, whose radius exceeds $2^{-j}R \geq r/2$. In both cases B meets $B' = \overline{B}(x',r') \in \mathcal{G}$ with $r' \geq r/2$. If $z \in B \cap B'$ and $y \in B$, then $d(y,x') \leq d(y,x) + d(x,z) + d(z,x') \leq 2r + r' \leq 5r'$. □

Theorem 28.22.6. *Let μ be an outer measure on a metric space X for which all Borel sets are μ-measurable (for instance $\mu = \mathcal{H}^s$, by Lemma 28.17.2). Let $A_1, A_2 \subseteq X$, $s > 0$ and $t \geq 0$, and suppose*

$$\Theta^{*s}(\mu, A_2, x) = \limsup_{r \to 0} \frac{\mu(A_2 \cap \overline{B}(x,r))}{\alpha(s)(2r)^s} \geq t \qquad \text{for all } x \in A_1.$$

Then $t\,\mathcal{H}^s(A_1) \leq \mu(A_2)$.

A Borel measure μ on X defines such an outer measure, $\mu^*(E) = \inf\{\mu(B) : B \supseteq E \text{ Borel}\}$. The infimum is attained, by the intersection of Borel sets $B_j \supseteq E$ with $\mu(B_j) \to \mu^*(E)$; and for B Borel, $E \subseteq X$ and a Borel $E' \supseteq E$ with $\mu(E') = \mu^*(E)$, $\mu^*(E \cap B) + \mu^*(E \setminus B) \leq \mu(E' \cap B) + \mu(E' \setminus B) = \mu^*(E)$, so B is μ^*-measurable. So the theorem applies to Borel measures as well. This is the form of the theorem in [Sim83], where $A_1 \subseteq A_2$ is assumed; the proof below does not use this inclusion. The sets A_1 and A_2 need not be measurable. The important special case is $A_1 = A_2$; the freedom to choose A_2 is used to localise, with $A_2 = A \cap U$ for an open set $U \supseteq A_1$. Note the direction: Theorem 28.22.4 and its generalisation Theorem 28.22.14 below bound μ from above where the density is small; this theorem bounds μ from below where the density is large, and loses no factor 2^s.

Proof. We may assume $t > 0$ and $\mu(A_2) < \infty$. Let $0 < t' < t$ and $\delta > 0$, and let $\mathcal{F}$ be the family of closed balls $\overline{B}(x,r)$ with $x \in A_1$, $0 < r < \delta$ and $\mu(A_2 \cap \overline{B}(x,r)) \geq t'\alpha(s)(2r)^s$. By hypothesis every $x \in A_1$ is the centre of balls of $\mathcal{F}$ of arbitrarily small radius. Let $\mathcal{G}$ be as in Lemma 28.22.5.

The balls of $\mathcal{G}$ are disjoint Borel sets, hence μ-measurable, and by the definition of measurability $\mu(A_2) \geq \sum_{B \in \mathcal{G}'} \mu(A_2 \cap B)$ for every finite $\mathcal{G}' \subseteq \mathcal{G}$ (split A_2 successively along the balls). Each term is at least $t'\alpha(s)(2r_B)^s > 0$, so only finitely many balls of $\mathcal{G}$ have $\mu(A_2 \cap B) > 1/m$, for each m; hence $\mathcal{G}$ is countable, say $\mathcal{G} = \{B_1, B_2, \ldots\}$ with radii r_i, and

$$\sum_i t'\alpha(s)(2r_i)^s \leq \sum_i \mu(A_2 \cap B_i) \leq \mu(A_2) < \infty.$$

We claim that $A_1 \subseteq \bigcup_{i \leq N} B_i \cup \bigcup_{i > N} \widehat{B}_i$ for every N. Let $x \in A_1$ lie outside the closed set $B_1 \cup \cdots \cup B_N$. Some closed ball around x misses this set, so there is $B \in \mathcal{F}$ centred at x and disjoint from $B_1, \ldots, B_N$. By the lemma B meets some B_i with $B \subseteq \widehat{B}_i$, and necessarily $i > N$; so $x \in \widehat{B}_i$.

The sets B_i and $\widehat{B}_i$ have diameters at most $2r_i < 2\delta$ and $10r_i < 10\delta$. Hence

$$\mathcal{H}^s_{10\delta}(A_1) \leq \sum_{i \leq N} \alpha(s)(2r_i)^s + \sum_{i > N} \alpha(s)(10r_i)^s \leq \frac{\mu(A_2)}{t'} + 5^s \sum_{i > N} \alpha(s)(2r_i)^s.$$

The last sum is the tail of a convergent series, so letting $N \to \infty$ gives $\mathcal{H}^s_{10\delta}(A_1) \leq \mu(A_2)/t'$. Letting $\delta \to 0$ and then $t' \to t$ proves the theorem. □

Together with Theorem 28.22.4 this gives the basic density estimates for sets of finite Hausdorff measure, in every metric space.

Theorem 28.22.7 (Upper density theorem)**.** *Let $A \subseteq X$ be $\mathcal{H}^s$-measurable with $\mathcal{H}^s(A) < \infty$, $s > 0$. Then $2^{-s} \le \Theta^{*s}(A, x) \le 1$ for $\mathcal{H}^s$-almost every $x \in A$, and $\Theta^{*s}(A, x) = 0$ for $\mathcal{H}^s$-almost every $x \in X \setminus A$.*

Proof. The lower bound is Theorem 28.22.4. Let $\nu(E) = \mathcal{H}^s(A \cap E)$ for Borel E; since A and E are $\mathcal{H}^s$-measurable, ν is a finite Borel measure, so by Lemma 28.14.1 every Borel set E has open neighbourhoods U with $\nu(U) < \nu(E) + \varepsilon$. For x in an open set U, small balls around x lie in U, so $\Theta^{*s}(\mathcal{H}^s \mathbin{\llcorner} A \cap U, x) = \Theta^{*s}(A, x)$.

Upper bound. Let $t > 1$ and $B = \{x \in A : \Theta^{*s}(A, x) > t\}$. By Borel regularity (Remark 28.17.4(2)) there is a Borel set $E \supseteq B$ with $\mathcal{H}^s(E) = \mathcal{H}^s(B)$, so $\nu(E) = \mathcal{H}^s(B)$, as $B \subseteq A \cap E \subseteq E$. For an open $U \supseteq E$ with $\nu(U) < \nu(E) + \varepsilon$, Theorem 28.22.6 with $\mu = \mathcal{H}^s$, $A_1 = B$, $A_2 = A \cap U$ gives $t\mathcal{H}^s(B) \le \mathcal{H}^s(A \cap U) = \nu(U) < \mathcal{H}^s(B) + \varepsilon$. As ε is arbitrary and $\mathcal{H}^s(B) < \infty$, $(t-1)\mathcal{H}^s(B) \le 0$, so $\mathcal{H}^s(B) = 0$. Taking $t = 1 + 1/j$, $j \ge 1$, gives the upper bound.

Outside A. Let $t > 0$ and $B = \{x \in X \setminus A : \Theta^{*s}(A, x) > t\}$. Choose a Borel set $A' \supseteq A$ with $\mathcal{H}^s(A') = \mathcal{H}^s(A)$; since A is measurable and of finite measure, $\mathcal{H}^s(A' \setminus A) = 0$, so $B \cap A'$ is null. The Borel set $X \setminus A'$ has $\nu(X \setminus A') = 0$, so it has open neighbourhoods U with $\nu(U) < \varepsilon$, and the theorem with $A_1 = B \setminus A'$, $A_2 = A \cap U$ gives $t\mathcal{H}^s(B \setminus A') \le \varepsilon$. Hence B is null, and taking $t = 1/j$ gives the last statement. □

The name comes from [Sim83]: the theorem is about upper densities only. In $\mathbb{R}^n$ with $s = n$ it says less than the Lebesgue density theorem, which gives density exactly 1 on A and 0 outside; but for non-integral s the density need not exist (Example 28.22.3), and the upper density is then the right object. For A the Cantor set the theorem says that $\Theta^{*s}(C, x) \in [2^{-s}, 1]$ at $\mathcal{H}^s$-almost every point of C.

So every set of finite s-dimensional measure is, at almost all of its points, at least somewhat dense and at most as dense as a flat piece. Whether the density exists, that is, whether the lower density equals the upper one, is a deep geometric property, and it is related to the following class of sets.

Definition 28.22.8. Let $k \ge 1$ be an integer. A set $A \subseteq \mathbb{R}^n$ is *countably k-rectifiable* if there are Lipschitz maps $g_j \colon E_j \to \mathbb{R}^n$, $E_j \subseteq \mathbb{R}^k$, $j = 1, 2, \ldots$, such that

$$\mathcal{H}^k\Big(A \setminus \bigcup_j g_j(E_j)\Big) = 0.$$

It is *purely k-unrectifiable* if $\mathcal{H}^k(A \cap g(E)) = 0$ for every Lipschitz map $g \colon E \to \mathbb{R}^n$ with $E \subseteq \mathbb{R}^k$.

So a rectifiable set is, up to a null set, a countable union of Lipschitz images of pieces of $\mathbb{R}^k$, and on such pieces Rademacher's theorem and the area formula give tangent planes and a calculus. A purely unrectifiable set meets each Lipschitz image of a piece of $\mathbb{R}^k$ only in a null set.

Proposition 28.22.9.

1. *Subsets and countable unions of countably k-rectifiable sets are countably k-rectifiable.*
2. *A countably k-rectifiable set A has $\dim_{\mathcal{H}} A \le k$, and $A \cap \bigcup_j g_j(E_j)$ has σ-finite $\mathcal{H}^k$-measure.*
3. *If $U \subseteq \mathbb{R}^k$ is open and $g \colon U \to \mathbb{R}^n$ is of class C^1, then $g(U)$ is countably k-rectifiable.*
4. *If A is countably k-rectifiable and B is purely k-unrectifiable, then $\mathcal{H}^k(A \cap B) = 0$.*

Proof. (1) is clear from the definition: a subset can use the same maps, and countably many countable families of maps form a countable family.

(2) Let L_j be a Lipschitz constant of g_j. For $m \geq 1$, Proposition 28.17.3(3) and Theorem 28.17.5 give $\mathcal{H}^k(g_j(E_j \cap [-m,m]^k)) \leq L_j^k \mathcal{H}^k([-m,m]^k) = L_j^k (2m)^k < \infty$. So $\bigcup_j g_j(E_j)$ is a countable union of sets of finite $\mathcal{H}^k$-measure, each of which has $\mathcal{H}^t$-measure 0 for $t > k$ (Proposition 28.17.3(4)); the remaining part of A is $\mathcal{H}^k$-null, hence also $\mathcal{H}^t$-null for $t > k$.

(3) U is the union of the countably many closed balls $\overline{B} \subseteq U$ with rational centres and radii. On such a ball, which is compact and convex, $\|Dg\|$ is bounded, say by L, and the mean value inequality (Proposition 27.10.3(4)) shows that g is L-Lipschitz on $\overline{B}$.

(4) $A \cap B$ is contained in the union of the $\mathcal{H}^k$-null set $A \setminus \bigcup_j g_j(E_j)$ and the sets $B \cap g_j(E_j)$, which are $\mathcal{H}^k$-null by assumption. □

By (3), images of C^1 maps, such as the curves of Example 28.22.2, graphs of C^1 or Lipschitz functions, and k-dimensional submanifolds of $\mathbb{R}^n$ (which are covered by countably many images of charts), are countably k-rectifiable. At the other extreme, the four-corner Cantor set K_4 of Example 28.18.11(2), which has $0 < \mathcal{H}^1(K_4) < \infty$, is purely 1-unrectifiable [Fal85], [Mat95]. The two classes are distinguished by densities and by projections, and these are among the deepest results of the subject.

Theorem 28.22.10. *Let $A \subseteq \mathbb{R}^n$ be $\mathcal{H}^k$-measurable with $0 < \mathcal{H}^k(A) < \infty$, k an integer with $1 \leq k < n$.*

1. *(*Densities*) A is countably k-rectifiable if and only if $\Theta^k(A,x) = 1$ for $\mathcal{H}^k$-almost every $x \in A$, and if and only if $\Theta^k(A,x)$ exists and is positive for $\mathcal{H}^k$-almost every $x \in A$.*

2. *(*Projections, Besicovitch–Federer*) If A is countably k-rectifiable, then its orthogonal projections to almost all k-dimensional linear subspaces have positive $\mathcal{H}^k$-measure. If A is purely k-unrectifiable, then its projections to almost all k-dimensional linear subspaces are $\mathcal{H}^k$-null.*

Here "almost all" refers to the rotation-invariant measure on the set of k-dimensional subspaces; for $k = 1$, $n = 2$ it means almost all angles. See [Mat95], [Fed69]; the last statement of (1) is Preiss's theorem [Pre87].

Remark 28.22.11.

1. *Non-integral dimensions.* If $0 < \mathcal{H}^s(A) < \infty$ and the density $\Theta^s(A,x)$ exists and is positive at almost every point of A, then s is an integer (Marstrand, see [Mat95]). So sets of non-integral dimension, such as the Cantor set (Example 28.22.3) and the self-similar sets of Section 28.18, are always irregular: their densities oscillate.

2. *The four-corner set again.* Example 28.18.12 computed two projections of K_4: in the direction of the axes it has length 0, as Theorem 28.22.10(2) predicts for almost all directions, while in the direction of $(2,1)$ it is an interval. So the exceptional set of directions in the Besicovitch–Federer theorem is not empty. For a segment the situation is reversed: its projection has positive length in every direction except the perpendicular one.

3. *Besicovitch and Kakeya sets.* A *Besicovitch set* is a compact subset of $\mathbb{R}^n$ that contains a segment of length 1 in every direction. Besicovitch showed that such sets exist in $\mathbb{R}^2$ with Lebesgue measure 0; correspondingly, a needle of length 1 can be turned around completely inside a region of arbitrarily small area (*Kakeya's needle problem*). Every Besicovitch set in $\mathbb{R}^2$ has Hausdorff dimension 2 (Davies), see [Fal85]. Whether Besicovitch sets in $\mathbb{R}^n$ must have Hausdorff dimension n is the *Kakeya conjecture*, a central problem linking geometric measure theory with harmonic analysis and analytic number theory.

28.22.1 Densities of measures

Nothing in the definition of densities is special to the Hausdorff measure of a set: one can ask how much mass any measure puts in small balls. This point of view, in which the set A is replaced by the measure $\mathcal{H}^s$ restricted to A, is the one used in modern geometric measure theory, and it simplifies the statements. Throughout, μ is a Borel measure on the metric space X that is finite on bounded Borel sets.

Definition 28.22.12. For $s > 0$ and $x \in X$, the *upper* and *lower s-dimensional densities* of μ at x are

$$\Theta^{*s}(\mu, x) = \limsup_{r \to 0} \frac{\mu(\overline{B}(x, r))}{\alpha(s)(2r)^s}, \qquad \Theta^s_*(\mu, x) = \liminf_{r \to 0} \frac{\mu(\overline{B}(x, r))}{\alpha(s)(2r)^s},$$

and the *density* $\Theta^s(\mu, x)$ is their common value when they agree.

Example 28.22.13.

1. If $A \subseteq X$ is a Borel set with $\mathcal{H}^s(A) < \infty$, then $\mu = \mathcal{H}^s \llcorner A$, $\mu(B) = \mathcal{H}^s(A \cap B)$, is such a measure (Borel sets are $\mathcal{H}^s$-measurable by Lemma 28.17.2), and $\Theta^{*s}(\mu, x) = \Theta^{*s}(A, x)$: the densities of Definition 28.22.1 are those of this measure.

2. For $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$ with $f \geq 0$ and $\mu = f\lambda$, $\Theta^n(\mu, x) = f(x)$ for almost every x, since $\alpha(n)(2r)^n = \lambda(\overline{B}(x, r))$ and the averages of f over balls converge to $f(x)$ almost everywhere (Theorem 28.9.4; closed and open balls differ by a null sphere). For $s < n$, $\Theta^s(\mu, x) = 0$ wherever f is bounded near x.

3. For a point mass $\mu = \delta_a$, $\Theta^{*s}(\mu, a) = \infty$ for every $s > 0$, and $\Theta^s(\mu, x) = 0$ for $x \neq a$.

4. For the Cantor measure μ of Example 28.17.6(3) and $s = \log 2 / \log 3$, part (4) of that example gives $\mu(\overline{B}(x, r)) \leq 2(2r)^s$ for $2r < 1$, so $\Theta^{*s}(\mu, x) \leq 2/\alpha(s)$ at every point. At 0 the density does not exist: $\mu([0, 3^{-k}]) = 2^{-k}$, and $\mu([0, 2 \cdot 3^{-k-1}]) = 2^{-k-1}$ because μ gives no mass to the gap $(3^{-k-1}, 2 \cdot 3^{-k-1})$ and none to points (the Cantor function is continuous), so the computation of Example 28.22.3 applies with $c = 1$.

The basic theorem compares μ with $\mathcal{H}^s$ on the set where the density of μ is bounded.

Theorem 28.22.14. *Let μ be a Borel measure on X, finite on bounded Borel sets, let $A \subseteq X$ be a Borel set, $s > 0$ and $0 < t < \infty$. If $\Theta^{*s}(\mu, x) \leq t$ for every $x \in A$, then*

$$\mu(A) \leq 2^s t \, \mathcal{H}^s(A).$$

Proof. Measurability. For fixed $r > 0$ the function $x \mapsto \mu(\overline{B}(x, r))$ is upper semicontinuous: if $x_j \to x$, then $\overline{B}(x_j, r) \subseteq \overline{B}(x, r + \eta)$ for large j, so $\limsup_j \mu(\overline{B}(x_j, r)) \leq \mu(\overline{B}(x, r + \eta))$ for every $\eta > 0$, and $\mu(\overline{B}(x, r + \eta)) \to \mu(\overline{B}(x, r))$ as $\eta \to 0$ by continuity from above, since $\overline{B}(x, r) = \bigcap_{\eta > 0} \overline{B}(x, r + \eta)$ and these balls have finite measure. So the sets $\{x : \mu(\overline{B}(x, r)) < c\}$ are open and the sets $\{x : \mu(\overline{B}(x, r)) \leq c\}$ are Borel. The same continuity shows that $r \mapsto \mu(\overline{B}(x, r))$ is right continuous.

Covering. Let $t' > t$ and, for $k \geq 1$,

$$A_k = \left\{ x \in A : \mu(\overline{B}(x, r)) \leq t' \alpha(s)(2r)^s \text{ for all } 0 < r < 1/k \right\}.$$

By right continuity it suffices to require the inequality for rational r, so A_k is Borel. The sets A_k increase, and their union is A, because $\Theta^{*s}(\mu, x) \leq t < t'$. Fix k, $0 < \delta < 1/k$ and $\varepsilon > 0$, and assume $\mathcal{H}^s(A_k) < \infty$ (otherwise there is nothing to prove). Choose a cover of A_k by closed sets C_i of diameter $d_i \leq \delta$ with $\sum_i \alpha(s) d_i^s \leq \mathcal{H}^s_\delta(A_k) + \varepsilon$, discard those not meeting A_k, and pick

$x_i \in C_i \cap A_k$. If $d_i > 0$, then $C_i \subseteq \overline{B}(x_i, d_i)$ with $d_i < 1/k$, so $\mu(C_i) \le t'\alpha(s)(2d_i)^s = 2^s t'\alpha(s) d_i^s$. If $d_i = 0$, then $C_i = \{x_i\}$ and $\mu(C_i) \le \mu(\overline{B}(x_i, r)) \le t'\alpha(s)(2r)^s$ for all small r, so $\mu(C_i) = 0$. Summing,

$$\mu(A_k) \le \sum_i \mu(C_i) \le 2^s t' \big(\mathcal{H}^s_\delta(A_k) + \varepsilon\big) \le 2^s t' \big(\mathcal{H}^s(A) + \varepsilon\big).$$

Letting $\varepsilon \to 0$, then $k \to \infty$ (continuity from below), then $t' \to t$ gives the claim. □

For $\mu = \mathcal{H}^s \llcorner A$ the argument is the proof of Theorem 28.22.4: on the set where $\Theta^{*s}(A, \cdot) \le t$ with $t < 2^{-s}$ the theorem gives $\mathcal{H}^s \le 2^s t \mathcal{H}^s$, which forces measure zero. The hypothesis $t > 0$ cannot be dropped: Lebesgue measure on $\mathbb{R}$ has $\Theta^{1/2}(\lambda, x) = 0$ everywhere, while $\lambda(\mathbb{R}) > 0$ and $\mathcal{H}^{1/2}(\mathbb{R}) = \infty$.

Corollary 28.22.15. *Let μ be as in the theorem and $s > 0$.*

1. *(*Absolute continuity*) If $\Theta^{*s}(\mu, x) < \infty$ for every x in a Borel set A, then every Borel set $E \subseteq A$ with $\mathcal{H}^s(E) = 0$ has $\mu(E) = 0$.*

2. *(*Mass distribution principle*) If A is a Borel set and there are $c, r_0 > 0$ with $\mu(\overline{B}(x, r)) \le c r^s$ for all $x \in A$ and $0 < r < r_0$, then $\mathcal{H}^s(A) \ge \alpha(s)\mu(A)/c$. In particular, if $\mu(A) > 0$ then $\dim_{\mathcal{H}} A \ge s$.*

Proof. (1) For integers $m, k \ge 1$ let $E_{m,k}$ be the set of $x \in E$ with $\mu(\overline{B}(x, r)) \le m\alpha(s)(2r)^s$ for $0 < r < 1/k$, a Borel set as in the proof above, on which $\Theta^{*s}(\mu, \cdot) \le m$. By the theorem $\mu(E_{m,k}) \le 2^s m \mathcal{H}^s(E_{m,k}) = 0$, and $E = \bigcup_{m,k} E_{m,k}$ because the upper density is finite on E. (2) On A, $\Theta^{*s}(\mu, x) \le c/(2^s\alpha(s))$, so the theorem gives $\mu(A) \le (c/\alpha(s))\mathcal{H}^s(A)$. If $\mu(A) > 0$, then $\mathcal{H}^s(A) > 0$, so $\dim_{\mathcal{H}} A \ge s$. □

For the Cantor measure, (2) with $c = 2^{1+s}$ gives $\mathcal{H}^s(C) \ge \alpha(s)2^{-1-s}$, a little weaker than the bound $\alpha(s)/2$ of Example 28.17.6, which estimated μ on arbitrary small sets rather than on balls. Statement (1) says that a measure with finite upper s-density cannot charge $\mathcal{H}^s$-null sets; for instance a measure with finite upper 1-density everywhere on $\mathbb{R}^2$ gives no mass to the Cantor set $C \times \{0\}$, of dimension $\log 2/\log 3 < 1$.

Remark 28.22.16.

1. *The reverse inequality.* Theorem 28.22.6 is the reverse of the theorem above: for μ as in the theorem, a Borel set A and an open $U \supseteq A$ with $t_1 \le \Theta^{*s}(\mu, x) \le t_2$ on A, they give $t_1\mathcal{H}^s(A) \le \mu(U)$ (as $\mu(U \cap \overline{B}(x, r)) = \mu(\overline{B}(x, r))$ for $x \in A$ and small r) and $\mu(A) \le 2^s t_2 \mathcal{H}^s(A)$; taking the infimum over U, which is $\mu(A)$ by outer regularity (Lemma 28.14.1, applied on bounded pieces), $t_1\mathcal{H}^s(A) \le \mu(A) \le 2^s t_2 \mathcal{H}^s(A)$. The factor 2^s on the right is lost because the proof encloses arbitrary sets of a cover in balls; the left inequality is proved with the $5r$-covering lemma, which works with balls from the start. For $\mu = \mathcal{H}^s \llcorner A$ the two inequalities are the two halves of the upper density theorem (Theorem 28.22.7).

2. *Differentiation of one measure by another.* For two Radon measures μ, ν on $\mathbb{R}^n$, the limit $\lim_{r\to 0} \nu(\overline{B}(x, r))/\mu(\overline{B}(x, r))$ exists for μ-almost every x and is the Radon–Nikodym derivative of the absolutely continuous part of ν with respect to μ [EG92, Chapter 1]. For $\mu = \lambda$ this is Theorem 28.16.3. For a general μ the Vitali covering lemma is useless, since $\mu(B(x, 3r))$ need not be comparable to $\mu(B(x, r))$, and it is replaced by the *Besicovitch covering theorem*, which uses the geometry of $\mathbb{R}^n$: if every point of a bounded set A is the centre of some ball of a family of closed balls with bounded radii, one can extract a subfamily that still covers A and in which no point lies in more than $N(n)$ balls, a number depending only on n. In a general metric space the Vitali argument survives when μ is doubling, $\mu(\overline{B}(x, 2r)) \le C\mu(\overline{B}(x, r))$; see Subsection 28.22.2.

3. *Rectifiable measures.* The rectifiability criteria have their natural form for measures. A Radon measure μ on $\mathbb{R}^n$ is *k-rectifiable* if $\mu = \theta \mathcal{H}^k \llcorner E$ with E countably k-rectifiable and θ a positive Borel function. *Preiss's theorem* says that μ is k-rectifiable if and only if $0 < \Theta^k(\mu, x) < \infty$ for μ-almost every x [Pre87], and *Marstrand's theorem* says that if $0 < \Theta^s(\mu, x) < \infty$ on a set of positive μ-measure, then s is an integer [Mat95]. Preiss's proof studies the *tangent measures* of μ at x, the weak limits (Section 28.15) of the rescaled measures $A \mapsto \mu(x + rA)/r^k$ as $r \to 0$; existence of the density forces them to be flat.

4. *Frostman's lemma.* The mass distribution principle has a converse: if $A \subseteq \mathbb{R}^n$ is a Borel set with $\mathcal{H}^s(A) > 0$, there is a nonzero finite Borel measure μ supported on a compact subset of A with $\mu(\overline{B}(x, r)) \le r^s$ for all x and r [Mat95]. So $\dim_{\mathcal{H}} A$ is the supremum of the s for which A carries a nonzero measure with $\mu(\overline{B}(x, r)) \le r^s$: Hausdorff dimension can be computed with measures instead of covers.

28.22.2 Differentiation with respect to doubling measures

Densities measure a measure μ against the function $r \mapsto \alpha(s)(2r)^s$. Measuring it against another measure ν instead, through the ratios $\mu(\overline{B}(x, r))/\nu(\overline{B}(x, r))$, leads to the general form of the Radon–Nikodym theorem in which the derivative $d\mu/d\nu$ is computed as a limit, as in Theorem 28.16.3 for $\nu = \lambda$. The proof there used $\lambda(3B) = 3^n\lambda(B)$, and the $5r$-covering lemma (Lemma 28.22.5) shows that a weak form of this property is all one needs, in any metric space. Throughout, X is a nonempty metric space, and for a Borel measure ν on X and any $A \subseteq X$ we write $\nu^*(A) = \inf\{\nu(E) : E \supseteq A \text{ Borel}\}$. This outer measure is countably subadditive (take a union of Borel supersets), and a set with $\nu^*(A) = 0$ lies in a Borel set of measure 0.

Definition 28.22.17. A Borel measure ν on X is *doubling* if $0 < \nu(\overline{B}(x, r)) < \infty$ for all $x \in X$ and $r > 0$, and there is a constant C with

$$\nu(\overline{B}(x, 2r)) \le C\, \nu(\overline{B}(x, r)) \qquad \text{for all } x \in X,\ r > 0.$$

Iterating, $\nu(\overline{B}(x, 2^k r)) \le C^k \nu(\overline{B}(x, r))$; in particular, for the enlarged ball $\widehat{B} = \overline{B}(x, 5r)$ of $B = \overline{B}(x, r)$,

$$\nu(\widehat{B}) \le \nu(\overline{B}(x, 8r)) \le C^3 \nu(B). \tag{28.6}$$

A doubling measure is finite on bounded sets, since every bounded set lies in a closed ball, and hence σ-finite: $X = \bigcup_k \overline{B}(x_0, k)$ for any $x_0 \in X$.

Example 28.22.18.

1. Lebesgue measure on $\mathbb{R}^n$ is doubling with $C = 2^n$, since $\lambda(\overline{B}(x, r)) = \alpha(n)(2r)^n$.

2. If w is a Borel function on $\mathbb{R}^n$ with $0 < m \le w \le M$, then $\nu = w\lambda$ is doubling with $C = 2^n M/m$: $\nu(\overline{B}(x, 2r)) \le M\lambda(\overline{B}(x, 2r)) = 2^n M\lambda(\overline{B}(x, r)) \le 2^n (M/m)\nu(\overline{B}(x, r))$.

3. The Gaussian measure $\gamma = e^{-y^2/2}\lambda$ on $\mathbb{R}$ is not doubling. For $x > 2$ the density $e^{-y^2/2}$ is decreasing on $[x - 2, x + 2]$, so

$$\frac{\gamma([x-2, x+2])}{\gamma([x-1, x+1])} \ge \frac{\frac{1}{2}e^{-(x-3/2)^2/2}}{2e^{-(x-1)^2/2}} = \frac{1}{4}e^{(x-5/4)/2},$$

estimating the numerator by the integral over $[x - 2, x - \frac{3}{2}]$; the right side is unbounded as $x \to \infty$. Far out, the measure of a ball is concentrated near its left end.

4. A point mass δ_a on $\mathbb{R}$ is not doubling, since balls missing a have measure 0; but δ_a is doubling on the one-point metric space $\{a\}$. Doubling is a property of the measure together with the metric space it lives on.

We need one approximation lemma, which replaces the role of $C_c(\mathbb{R}^n)$ in the Lebesgue differentiation theorem.

Lemma 28.22.19. *Let ν be a finite Borel measure on a metric space X and $1 \le p < \infty$. The bounded Lipschitz functions are dense in $L^p(\nu)$.*

Proof. By Proposition 28.2.6(4) and dominated convergence, simple functions $\sum_i a_i \mathbf{1}_{E_i}$ with E_i Borel are dense, so it suffices to approximate $\mathbf{1}_E$ for a Borel set E. Let $\varepsilon > 0$. By Lemma 28.14.1 there is a closed set $F \subseteq E$ with $\nu(E \setminus F) < \varepsilon$, so $\|\mathbf{1}_E - \mathbf{1}_F\|_p^p < \varepsilon$. If $F = \emptyset$, then $\|\mathbf{1}_E\|_p^p < \varepsilon$ and 0 approximates. Otherwise let $g_k(x) = \max(0, 1 - k\, d(x, F))$. It is Lipschitz with constant k, takes values in $[0,1]$, equals 1 on F, and $g_k(x) \to 0$ for $x \notin F$ because $d(x,F) > 0$ for such x, F being closed. So $g_k \to \mathbf{1}_F$ pointwise with $|g_k - \mathbf{1}_F| \le 1$, and as ν is finite, dominated convergence gives $\|g_k - \mathbf{1}_F\|_p \to 0$. □

From now on ν is a doubling measure on X with constant C.

Theorem 28.22.20 (Maximal inequality for doubling measures)**.** *Let $f \in L^1(\nu)$ and $t > 0$, and let A be the set of $x \in X$ such that*

$$\frac{1}{\nu(\overline{B}(x,r))} \int_{\overline{B}(x,r)} |f|\, d\nu > t \qquad \text{for some } 0 < r \le 1.$$

Then $\nu^*(A) \le C^3 \|f\|_1 / t$.

Proof. Let $\mathcal{F}$ be the family of balls $B = \overline{B}(x,r)$ with $x \in A$, $0 < r \le 1$ and $\int_B |f|\, d\nu > t\nu(B)$; every point of A is the centre of a ball of $\mathcal{F}$. Let $\mathcal{G}$ be the disjoint subfamily of Lemma 28.22.5. For finitely many balls of $\mathcal{G}$ the integrals $\int_B |f|\, d\nu$ add up to at most $\|f\|_1$, and each of them is $> t\nu(B) > 0$; so for each m only finitely many exceed $1/m$, and $\mathcal{G} = \{B_1, B_2, \ldots\}$ is countable. Every ball of $\mathcal{F}$ lies in some $\widehat{B_i}$, so $A \subseteq \bigcup_i \widehat{B_i}$, and by (28.6)

$$\nu^*(A) \le \sum_i \nu(\widehat{B_i}) \le C^3 \sum_i \nu(B_i) < \frac{C^3}{t} \sum_i \int_{B_i} |f|\, d\nu \le \frac{C^3}{t} \|f\|_1.$$

(If A is empty there is nothing to prove.) □

Theorem 28.22.21 (Lebesgue differentiation theorem for doubling measures)**.** *Let $f : X \to \mathbb{R}$ be a Borel function with $\int_B |f|\, d\nu < \infty$ for every closed ball B. For ν-almost every $x \in X$,*

$$\lim_{r \to 0} \frac{1}{\nu(\overline{B}(x,r))} \int_{\overline{B}(x,r)} |f(y) - f(x)|\, d\nu(y) = 0,$$

and in particular the averages of f over $\overline{B}(x,r)$ tend to $f(x)$.

Proof. Write $\langle g \rangle_{x,r}$ for the average of a function g over $\overline{B}(x,r)$ with respect to ν, and $\Omega(x) = \limsup_{r \to 0} \langle |f - f(x)| \rangle_{x,r}$. Fix $x_0 \in X$, an integer $k \ge 1$, $t > 0$ and $\varepsilon > 0$, and let $D = \overline{B}(x_0, k+1)$. The measure $E \mapsto \nu(E \cap D)$ is finite, so by Lemma 28.22.19 there is a bounded continuous g with $\int_D |f - g|\, d\nu < \varepsilon$. Let $h = (f - g)\mathbf{1}_D$, so $\|h\|_1 < \varepsilon$.

Let $x \in B(x_0, k)$ and $0 < r \le 1$. Then $\overline{B}(x,r) \subseteq D$, and for $y \in \overline{B}(x,r)$

$$|f(y) - f(x)| \le |h(y)| + |h(x)| + |g(y) - g(x)|.$$

Averaging over y gives $\langle |f - f(x)| \rangle_{x,r} \le \langle |h| \rangle_{x,r} + |h(x)| + \sup_{\overline{B}(x,r)} |g - g(x)|$, and the last term tends to 0 as $r \to 0$ because g is continuous. So, if $\Omega(x) > 2t$, then either $\langle |h| \rangle_{x,r} > t$ for some $r \le 1$, or $|h(x)| > t$. By Theorem 28.22.20 and Markov's inequality (Corollary 28.4.4(4)),

$$\nu^*\big(\{x \in B(x_0,k) : \Omega(x) > 2t\}\big) \le \frac{C^3\varepsilon}{t} + \frac{\varepsilon}{t}.$$

As ε is arbitrary, this set has outer measure 0. The set where $\Omega > 0$ is the union of these sets over $k \ge 1$ and $t = 1/j$, $j \ge 1$, so it has outer measure 0 and lies in a ν-null Borel set. Finally $|\langle f \rangle_{x,r} - f(x)| \le \langle |f - f(x)| \rangle_{x,r}$. □

Theorem 28.22.22 (Differentiation of measures with respect to a doubling measure)**.** *Let μ be a Borel measure on X that is finite on bounded Borel sets, and let $\mu = h\nu + \mu_s$ be its Lebesgue decomposition with respect to ν (Theorem 28.12.3), with $h \ge 0$ Borel and $\mu_s \perp \nu$. Then for ν-almost every x*

$$\lim_{r \to 0} \frac{\mu(\overline{B}(x,r))}{\nu(\overline{B}(x,r))} = h(x).$$

In particular, if $\mu \ll \nu$, the Radon–Nikodym derivative is $\frac{d\mu}{d\nu}(x) = \lim_{r\to 0} \mu(\overline{B}(x,r))/\nu(\overline{B}(x,r))$ for ν-almost every x; and $\mu \perp \nu$ if and only if this limit is 0 ν-almost everywhere.

Proof. Both measures are σ-finite, X being the union of the balls $\overline{B}(x_0,k)$, so the decomposition exists. For every closed ball B, $\int_B h\,d\nu \le \mu(B) < \infty$, so by Theorem 28.22.21 the averages of h over $\overline{B}(x,r)$ tend to $h(x)$ for almost every x. Since

$$\frac{\mu(\overline{B}(x,r))}{\nu(\overline{B}(x,r))} = \frac{1}{\nu(\overline{B}(x,r))} \int_{\overline{B}(x,r)} h\,d\nu + \frac{\mu_s(\overline{B}(x,r))}{\nu(\overline{B}(x,r))},$$

it remains to show that the last ratio tends to 0 for almost every x.

Let S be a Borel set with $\nu(S) = 0$ and $\mu_s(X \setminus S) = 0$. Fix $x_0 \in X$, $k \ge 1$, $t > 0$ and $\varepsilon > 0$, and let A be the set of $x \in B(x_0,k) \setminus S$ with $\limsup_{r\to 0} \mu_s(\overline{B}(x,r))/\nu(\overline{B}(x,r)) > t$. The measure $E \mapsto \mu_s(E \cap B(x_0,k+1))$ is finite and vanishes on the Borel set $B(x_0,k) \setminus S$, so by Lemma 28.14.1 there is an open $U' \supseteq B(x_0,k) \setminus S$ with $\mu_s(U' \cap B(x_0,k+1)) < \varepsilon$. The set $U = U' \cap B(x_0,k+1)$ is open, contains A, and has $\mu_s(U) < \varepsilon$.

Let $\mathcal{F}$ be the family of balls $B = \overline{B}(x,r)$ with $x \in A$, $r \le 1$, $B \subseteq U$ and $\mu_s(B) > t\nu(B)$. Each $x \in A$ is the centre of such balls, because $\overline{B}(x,r) \subseteq U$ for small r. Let $\mathcal{G}$ be the disjoint subfamily of Lemma 28.22.5. Its balls lie in the bounded set U, which has finite ν-measure, and have positive ν-measure, so $\mathcal{G} = \{B_1, B_2, \ldots\}$ is countable, as in the proof of Theorem 28.22.20. As there, $A \subseteq \bigcup_i \widehat{B}_i$ and

$$\nu^*(A) \le C^3 \sum_i \nu(B_i) < \frac{C^3}{t} \sum_i \mu_s(B_i) \le \frac{C^3}{t}\mu_s(U) < \frac{C^3\varepsilon}{t}.$$

So $\nu^*(A) = 0$. Taking the union over k and $t = 1/j$, and adding the null set S, the ratio $\mu_s(\overline{B}(x,r))/\nu(\overline{B}(x,r))$ tends to 0 outside a ν-null set.

If $\mu \ll \nu$, then $\mu_s = 0$ by uniqueness of the decomposition, and $h = d\mu/d\nu$ is the Radon–Nikodym derivative (Theorem 28.12.2). If $\mu \perp \nu$, then $h\nu = 0$ by uniqueness, so $h = 0$ almost everywhere; conversely, if the limit is 0 almost everywhere, then $h = 0$ almost everywhere and $\mu = \mu_s$. □

So the Radon–Nikodym derivative, obtained abstractly in Theorem 28.12.2, is a limit of ratios of measures of balls whenever the reference measure is doubling. For $f \in L^1_{\mathrm{loc}}$ and $\mu = f\nu$ the theorem is the Lebesgue differentiation theorem again; for $\mu = \nu \llcorner E$, E Borel, it is a density theorem: $\nu(E \cap \overline{B}(x,r))/\nu(\overline{B}(x,r))$ tends to 1 at almost every point of E and to 0 at almost every point outside E.

Remark 28.22.23.

1. *Densities as derivatives.* The density $\Theta^s(\mu, x)$ is the derivative of μ with respect to the function $r \mapsto \alpha(s)(2r)^s$ in place of a measure ν. Since this function is not the measure of the balls of a fixed measure, there is no Lebesgue decomposition to recover, and one only gets the inequalities of Theorems 28.22.6 and 28.22.14. The proofs are parallel: the singular part was handled above exactly as in Theorem 28.22.6, with $\nu(B)$ in place of $\alpha(s)(2r)^s$ for $B = \overline{B}(x,r)$, and with (28.6) in place of $\alpha(s)(10r)^s = 5^s\alpha(s)(2r)^s$.

2. *Beyond doubling.* Doubling is sufficient, not necessary. On $\mathbb{R}^n$ every Radon measure can serve as ν, by the Besicovitch covering theorem (Remark 28.16.6 and Remark 28.22.16(2)); so the non-doubling Gaussian measure of Example 28.22.18(3) still differentiates. In general metric spaces some covering property is needed; spaces with a doubling measure, the *spaces of homogeneous type*, are the standard setting for analysis on metric spaces [Hei01, Chapter 1].

3. *Ahlfors regularity.* A measure ν with $c^{-1}r^s \le \nu(\overline{B}(x,r)) \le cr^s$ for all $x \in X$ and $0 < r \le \operatorname{diam} X$ (so $c \ge 1$) is doubling with $C = 2^s c^2$: if $2r \le \operatorname{diam} X$, then $\nu(\overline{B}(x,2r)) \le c2^s r^s \le 2^s c^2 \nu(\overline{B}(x,r))$; if $r \le \operatorname{diam} X < 2r$, then $\nu(\overline{B}(x,2r)) = \nu(\overline{B}(x,\operatorname{diam} X)) \le c(2r)^s \le 2^s c^2 \nu(\overline{B}(x,r))$; and if $r > \operatorname{diam} X$, both balls are X. For such a measure, ν and $\mathcal{H}^s$ are comparable on Borel sets A: $\nu(A) \le (c/\alpha(s))\mathcal{H}^s(A)$ by Theorem 28.22.14, and $\mathcal{H}^s(A) \le 2^s c\,\alpha(s)\nu(U)$ for every open $U \supseteq A$ by Theorem 28.22.6 with $A_1 = A$, $A_2 = U$, which gives $\mathcal{H}^s(A) \le 2^s c\,\alpha(s)\nu(A)$ by outer regularity (Lemma 28.14.1, applied on bounded pieces). The Cantor measure on the Cantor set C is of this kind with $s = \log 2/\log 3$: Example 28.22.13(4) gives the upper bound, and for $x \in C$ and $3^{-k} \le r < 3^{1-k}$ the ball $\overline{B}(x,r)$ contains the interval of the k-th stage of the construction that contains x, of measure $2^{-k} = (3^{-k})^s \ge 3^{-s}r^s$.

Exercise 28.22.24. Let ν be a doubling measure on X with constant C.

1. Let $0 < \varepsilon \le R$ and let $m \ge 0$ be an integer with $2^m\varepsilon \ge 2R$. Show that a set of points of $\overline{B}(x,R)$ with pairwise distances $> 2\varepsilon$ has at most C^{m+1} elements.

2. Deduce that closed balls in X are totally bounded, that X is separable, and that if X is complete, closed balls are compact.

3. Deduce that the Hilbert space ℓ^2 of square-summable real sequences carries no doubling measure.

Solution. (1) Let $y_1, \dots, y_N \in \overline{B}(x,R)$ with $d(y_i,y_j) > 2\varepsilon$ for $i \ne j$. The balls $\overline{B}(y_i,\varepsilon)$ are pairwise disjoint and lie in $\overline{B}(x,R+\varepsilon) \subseteq \overline{B}(x,2R)$. Moreover $\overline{B}(x,R) \subseteq \overline{B}(y_i,2R)$, so $\nu(\overline{B}(x,R)) \le \nu(\overline{B}(y_i,2R)) \le C^m\nu(\overline{B}(y_i,2^{-m}2R)) \le C^m\nu(\overline{B}(y_i,\varepsilon))$. Summing over i,

$$NC^{-m}\nu(\overline{B}(x,R)) \le \sum_i \nu(\overline{B}(y_i,\varepsilon)) \le \nu(\overline{B}(x,2R)) \le C\nu(\overline{B}(x,R)),$$

and dividing by $\nu(\overline{B}(x,R)) > 0$ gives $N \le C^{m+1}$.

(2) Given $\varepsilon \le R$, choose a set $\{y_1,\dots,y_N\} \subseteq \overline{B}(x,R)$ with pairwise distances $> 2\varepsilon$ and with N as large as possible, which is possible by (1). Every $y \in \overline{B}(x,R)$ has $d(y,y_i) \le 2\varepsilon$

for some i, since otherwise y could be added. So finitely many open balls of radius 3ε cover $\overline{B}(x, R)$; for $\varepsilon > R$ the single ball $B(x, 3\varepsilon)$ does. Hence $\overline{B}(x, R)$ is totally bounded. A totally bounded metric space is separable (the centres of finite $1/j$-nets, $j \geq 1$, form a dense countable set), and $X = \bigcup_k \overline{B}(x_0, k)$ is a countable union of such spaces, so X is separable. A closed subset of a complete space is complete, so if X is complete, closed balls are compact by Theorem 18.7.4.

(3) The unit vectors $e_1, e_2, \ldots$ lie in the closed unit ball of ℓ^2 and have pairwise distances $\|e_i - e_j\| = \sqrt{2}$. So the closed unit ball is not totally bounded: no finitely many balls of radius $\frac{1}{2}$ cover it, since each such ball contains at most one e_i. By (2), there is no doubling measure on ℓ^2. Doubling measures live on spaces that are "finite-dimensional" in a metric sense. □

28.23 Exercises

Exercise 28.23.1. Show that the Cantor set, obtained from $[0, 1]$ by repeatedly removing open middle thirds, is compact, uncountable and of Lebesgue measure zero.

Solution. It is an intersection of closed subsets of $[0, 1]$, hence compact. After k steps it is covered by 2^k intervals of length 3^{-k}, so its measure is at most $(2/3)^k$. Its points are the numbers $\sum_k a_k 3^{-k}$ with $a_k \in \{0, 2\}$, and distinct sequences give distinct numbers, so it is in bijection with $\{0, 1\}^{\mathbb{N}}$, which is uncountable (Theorem 3.6.3). □

Exercise 28.23.2. (Borel–Cantelli.) If $\sum_k \mu(A_k) < \infty$, show that almost every point lies in only finitely many A_k.

Solution. By monotone convergence $\int \sum_k \mathbf{1}_{A_k} = \sum_k \mu(A_k) < \infty$, so $\sum_k \mathbf{1}_{A_k} < \infty$ a.e. □

Exercise 28.23.3. Show that there is no Lebesgue measurable $A \subseteq \mathbb{R}$ with $\lambda(A \cap I) = \frac{1}{2}\lambda(I)$ for every bounded interval I.

Solution. For such A, $\lambda(A \cap B(x, r))/\lambda(B(x, r)) = \frac{1}{2}$ for all x and r. By Corollary 28.9.5 this ratio tends to 1 at almost every point of A and to 0 at almost every point outside A; so A and $\mathbb{R} \setminus A$ are both null, which is impossible. □

Exercise 28.23.4. Show that $Mf \notin L^1(\mathbb{R}^n)$ for every $f \in L^1(\mathbb{R}^n)$ that is not zero almost everywhere; so the maximal inequality cannot be improved to $\|Mf\|_1 \leq C\|f\|_1$.

Solution. Choose R with $a = \int_{B(0,R)} |f| > 0$. For $\|x\| \geq R$, the ball $B(x, 2\|x\|)$ contains $B(0, R)$, so $Mf(x) \geq a/\lambda(B(x, 2\|x\|)) = a/(2^n\|x\|^n\lambda(B(0, 1)))$. The function $\|x\|^{-n}$ is not integrable on $\{\|x\| \geq R\}$: the shells $2^k R \leq \|x\| < 2^{k+1}R$ have measure $(2^n - 1)2^{kn}R^n\lambda(B(0, 1))$, and on each of them $\|x\|^{-n} \geq 2^{-(k+1)n}R^{-n}$, so each contributes at least the positive constant $(1 - 2^{-n})\lambda(B(0, 1))$ to the integral. □

Exercise 28.23.5. Show that $L^q(\mu) \subseteq L^p(\mu)$ for $p \leq q$ if $\mu(X) < \infty$, and that there is no inclusion in either direction for Lebesgue measure on $\mathbb{R}$.

Solution. By Hölder with exponents q/p and its conjugate, $\int |f|^p \leq (\int |f|^q)^{p/q}\mu(X)^{1-p/q}$. On $\mathbb{R}$, $|x|^{-1/2}\mathbf{1}_{[-1,1]}$ is in L^1 but not L^2, and $(1 + |x|)^{-1}$ is in L^2 but not L^1. □

Exercise 28.23.6. For $f \in L^1(\mathbb{R}^n)$ and $g \in L^p(\mathbb{R}^n)$, show using Fubini's theorem that $(f * g)(x) = \int f(x - y)g(y)\,dy$ is defined a.e. and $\|f * g\|_p \leq \|f\|_1\|g\|_p$.

Exercise 28.23.7. Show that the volume of the unit ball in $\mathbb{R}^n$ is $\omega_n = \pi^{n/2}/\Gamma(\frac{n}{2} + 1)$, where $\Gamma(s) = \int_0^\infty t^{s-1}e^{-t}\,dt$, by computing $\int_{\mathbb{R}^n} e^{-\|x\|^2}$ in two ways.

Exercise 28.23.8. Let $K \subseteq [0,1]$ be the set obtained by removing the open middle half $(\frac{1}{4}, \frac{3}{4})$ of $[0,1]$, then the open middle halves of the two remaining intervals, and so on; equivalently, the numbers $\sum_{k\geq 1} a_k 4^{-k}$ with all $a_k \in \{0,3\}$. Show that $\dim_{\mathcal{H}} K = \frac{1}{2}$.

Solution. Follow Example 28.17.6 with 3 replaced by 4 and the digits $\{0,2\}$ by $\{0,3\}$; now $s = \log 2/\log 4 = \frac{1}{2}$, so $4^s = 2$. The 2^k intervals of generation k have length 4^{-k}, which gives $\mathcal{H}^{1/2}(K) \leq \alpha(\frac{1}{2})2^k 4^{-k/2} = \alpha(\frac{1}{2})$. Two of them first differing at position $j \leq k$ have left ends differing by at least $3\cdot 4^{-j} - \sum_{j<i\leq k} 3\cdot 4^{-i} \geq 2\cdot 4^{-j}$, so they are at distance at least 4^{-k}. The function $F(\sum_k a_k 4^{-k}) = \sum_k (a_k/3)2^{-k}$ on K, extended to $[0,1]$ as in Counterexample 28.9.7, is continuous and nondecreasing, and its measure μ_F (Lemma 28.13.3) gives mass 2^{-k} to each interval of generation k and mass 0 to $[0,1]\setminus K$. A closed set of diameter d with $4^{-k-1} \leq d < 4^{-k}$ meets at most one interval of generation k, so its μ_F-measure is at most $2^{-k} = 2\cdot 4^{-(k+1)/2} \leq 2d^{1/2}$, and as in the example $\mathcal{H}^{1/2}(K) \geq \alpha(\frac{1}{2})/2 > 0$. □

Exercise 28.23.9. Let $h\colon \mathbb{R}^n \to \mathbb{R}$ be Lipschitz with constant L and $U \subseteq \mathbb{R}^n$ a bounded open set. Show that the graph $\Gamma = \{(x, h(x)) : x \in U\}$ satisfies $\lambda^n(U) \leq \mathcal{H}^n(\Gamma) \leq (1+L^2)^{n/2}\lambda^n(U)$, so that $\dim_{\mathcal{H}} \Gamma = n$, even though h need not be differentiable everywhere.

Solution. The map $g(x) = (x, h(x))$ satisfies $|g(x) - g(y)|^2 = |x-y|^2 + |h(x)-h(y)|^2 \leq (1+L^2)|x-y|^2$, so it is $\sqrt{1+L^2}$-Lipschitz, and its inverse, the projection $\Gamma \to U$, is 1-Lipschitz. By Proposition 28.17.3(3) and Theorem 28.17.5, $\lambda^n(U) = \mathcal{H}^n(U) \leq \mathcal{H}^n(\Gamma) \leq (1+L^2)^{n/2}\mathcal{H}^n(U)$. Both bounds are positive and finite, so $\mathcal{H}^s(\Gamma)$ is ∞ for $s < n$ and 0 for $s > n$ by Proposition 28.17.3(4). (By the general area formula of Remark 28.20.9 and Rademacher's theorem, $\mathcal{H}^n(\Gamma) = \int_U \sqrt{1+|\nabla h|^2}$.) □

Exercise 28.23.10. For $R > r > 0$ let $x(u,v) = ((R + r\cos u)\cos v, (R + r\cos u)\sin v, r\sin u)$. Show that x is injective with injective differential on $(0,2\pi)^2$, that $Jx = r(R + r\cos u)$, and that the torus $T = x(\mathbb{R}^2)$ has $\mathcal{H}^2(T) = 4\pi^2 Rr$.

Solution. $x_u = (-r\sin u\cos v, -r\sin u\sin v, r\cos u)$ and $x_v = (-(R+r\cos u)\sin v, (R+r\cos u)\cos v, 0)$ are orthogonal, of lengths r and $R + r\cos u > 0$, so $Jx = |x_u \times x_v| = r(R + r\cos u)$ and Dx is injective. The point $x(u,v)$ determines v modulo 2π (its projection to the plane $z = 0$ has argument v) and then u modulo 2π, so x is injective on $(0,2\pi)^2$. Its image is T minus the two circles $u = 0$ and $v = 0$, which have finite $\mathcal{H}^1$-measure and are therefore $\mathcal{H}^2$-null. By the area formula, $\mathcal{H}^2(T) = \int_0^{2\pi}\int_0^{2\pi} r(R + r\cos u)\,du\,dv = 4\pi^2 Rr$. □

Exercise 28.23.11. Let $(X, \mathcal{A}, \mu)$ be a complete measure space, f measurable and $g = f$ almost everywhere. Show that g is measurable. Deduce that for Lebesgue measure, changing a measurable function on a null set gives a measurable function, so that "measurable function defined almost everywhere" makes sense.

Solution. Let $N \in \mathcal{A}$ be a null set with $f = g$ outside N. For $a \in \mathbb{R}$, $\{g > a\} = (\{f > a\}\setminus N) \cup (\{g > a\} \cap N)$. The first set is measurable, and the second is a subset of the null set N, hence measurable by completeness. So g is measurable (Proposition 28.2.6(1)). Lebesgue measure is complete (Theorem 28.3.4). □

Exercise 28.23.12. For $A \subseteq [0,1]$ define the *inner measure* $\lambda_*(A) = \sup\{\lambda(K) : K \subseteq A \text{ compact}\}$, approximating A from inside instead of from outside. Show that $\lambda_*(A) = 1 - \lambda^*([0,1]\setminus A)$, that $\lambda_*(A) \leq \lambda^*(A)$, and that A is Lebesgue measurable if and only if $\lambda_*(A) = \lambda^*(A)$. (This was Lebesgue's original definition of measurability.)

Solution. Compact subsets $K \subseteq A$ correspond to relatively open sets $V = [0,1] \setminus K \supseteq [0,1] \setminus A$, with $\lambda(K) = 1 - \lambda(V)$; and $\lambda^*(B)$ is the infimum of $\lambda(U \cap [0,1])$ over open $U \supseteq B$ for $B \subseteq [0,1]$ (enlarge the covering boxes, as in the proof of Theorem 28.3.4). This gives the formula. If $K \subseteq A \subseteq U$ then $\lambda(K) \le \lambda^*(A) \le \lambda(U)$, so $\lambda_* \le \lambda^*$. If A is measurable, equality is inner regularity. Conversely, if $\lambda_*(A) = \lambda^*(A)$, choose compact $K_n \subseteq A$ and open $U_n \supseteq A$ with $\lambda(K_n) \to \lambda_*(A)$ and $\lambda(U_n) \to \lambda^*(A)$; then $F = \bigcup K_n \subseteq A \subseteq G = \bigcap U_n$ are Borel sets with $\lambda(G \setminus F) = \lambda(G) - \lambda(F) = 0$, so $A = F \cup (A \setminus F)$ with $A \setminus F \subseteq G \setminus F$ null, and A is measurable by completeness. □

Exercise 28.23.13. Let σ be the measure on $\mathbb{R}^2$ of Example 28.14.5(3), and $\varphi(t) = (\cos t, \sin t)$. Show that $\sigma(E) = \lambda(\{t \in [0, 2\pi] : \varphi(t) \in E\})$ for every Borel set E, and deduce that an arc $\{\varphi(t) : \alpha < t < \beta\}$ with $0 \le \alpha < \beta \le 2\pi$ has measure $\beta - \alpha$.

Solution. The right side defines a finite Borel measure ν, the push-forward of λ restricted to $[0, 2\pi]$, since preimages under the continuous φ of Borel sets are Borel. For $f = \mathbf{1}_E$, $\int f \, d\nu = \int_{[0,2\pi]} f \circ \varphi \, d\lambda$ by definition; by linearity this holds for simple functions, by monotone convergence for measurable $f \ge 0$, and then for $f \in C_c(\mathbb{R}^2)$. By Proposition 28.4.9, $\int_{[0,2\pi]} f \circ \varphi \, d\lambda = \Lambda f$. So ν represents Λ, and $\nu = \sigma$ by the uniqueness in Theorem 28.14.6. Since φ is injective on $[0, 2\pi)$ and $\varphi(2\pi) = \varphi(0)$, the set of $t \in [0, 2\pi]$ with $\varphi(t)$ in the arc is (α, β), of measure $\beta - \alpha$. □

Exercise 28.23.14. Let $\mu_k \rightharpoonup \mu$ be Radon measures on X (locally compact Hausdorff with a countable basis).

1. Show that $\mu(X) \le \liminf_k \mu_k(X)$, and that $\mu_k(X) \to \mu(X)$ if X is compact.
2. Suppose that the μ_k and μ are probability measures. Show that $\int f \, d\mu_k \to \int f \, d\mu$ for every bounded continuous $f : X \to \mathbb{R}$.

Solution. (1) The first statement is Proposition 28.15.3(1) with $U = X$; if X is compact, $1 \in C_c(X)$. (2) Let $\varepsilon > 0$. By inner regularity choose a compact K with $\mu(K) > 1 - \varepsilon$, and $\phi \in C_c(X)$ with $0 \le \phi \le 1$ and $\phi = 1$ on K. Then $\int \phi \, d\mu_k \to \int \phi \, d\mu > 1 - \varepsilon$, so $\int (1 - \phi) \, d\mu_k < 2\varepsilon$ for k large, while $\int (1 - \phi) \, d\mu < \varepsilon$. As $f\phi \in C_c(X)$,

$$\left| \int f \, d\mu_k - \int f \, d\mu \right| \le \left| \int f\phi \, d\mu_k - \int f\phi \, d\mu \right| + \|f\|_\infty \Big(\int (1 - \phi) \, d\mu_k + \int (1 - \phi) \, d\mu \Big),$$

whose lim sup is at most $3\varepsilon \|f\|_\infty$. So when no mass is lost, testing against $C_c(X)$ and against bounded continuous functions give the same notion of convergence. □

Exercise 28.23.15. *Length is not continuous.* For $k \ge 1$ let $\gamma_k(x) = (x, \frac{1}{k} \sin kx)$ for $x \in [0, 2\pi]$, and let μ_k be the length measure of γ_k, the Radon measure on $\mathbb{R}^2$ with

$$\int f \, d\mu_k = \int_0^{2\pi} f(\gamma_k(x)) \, |\gamma_k'(x)| \, dx = \int_0^{2\pi} f\big(x, \tfrac{1}{k} \sin kx\big) \sqrt{1 + \cos^2 kx} \, dx.$$

Show that $\gamma_k \to \gamma_0$, $\gamma_0(x) = (x, 0)$, uniformly, that $\mu_k \rightharpoonup c\mu_0$ with $c = \frac{1}{2\pi} \int_0^{2\pi} \sqrt{1 + \cos^2 t} \, dt$, where μ_0 is the length measure of the segment, and that $c > 1$. So the curves γ_k have length $2\pi c$, which does not converge to the length 2π of the limit curve.

Solution. $|\gamma_k(x) - \gamma_0(x)| \le 1/k$. Let $f \in C_c(\mathbb{R}^2)$, with modulus of uniform continuity ω. Then $|f(\gamma_k(x)) - f(x, 0)| \le \omega(1/k)$, so $\int f \, d\mu_k$ differs from $\int_0^{2\pi} f(x, 0) g(kx) \, dx$, where $g(t) = \sqrt{1 + \cos^2 t}$, by at most $2\pi\sqrt{2} \, \omega(1/k)$. The argument of Example 28.15.2(5), applied on

$[0,2\pi]$ to the continuous function $x \mapsto f(x,0)$ (only its continuity on $[0,2\pi]$ was used), shows that $\int_0^{2\pi} f(x,0)g(kx)\,dx \to \bar{g}\int_0^{2\pi} f(x,0)\,dx = c\int f\,d\mu_0$. Since $g \geq 1$, with equality only where $\cos t = 0$, and g is continuous, $c > 1$. The length of γ_k is $\int_0^{2\pi} g(kx)\,dx = \frac{1}{k}\int_0^{2\pi k} g = 2\pi c$, as the interval consists of k periods. In general length is only *lower semicontinuous* under uniform convergence of curves: the limit can be shorter, never longer. □

Exercise 28.23.16. Let μ be a Radon measure on $\mathbb{R}^n$ and $r > 0$. Show that $x \mapsto \mu(B(x,r))$ is lower semicontinuous and $x \mapsto \mu(\overline{B}(x,r))$ is upper semicontinuous, and that for fixed x the sphere $\{y : \|y-x\| = r\}$ has μ-measure 0 for all but countably many r.

Solution. Let $x_k \to x$. If $\|y-x\| < r$, then $\|y-x_k\| < r$ for k large, so $\mathbf{1}_{B(x,r)} \leq \liminf_k \mathbf{1}_{B(x_k,r)}$, and Fatou's lemma (Corollary 28.4.4) gives $\mu(B(x,r)) \leq \liminf_k \mu(B(x_k,r))$. If $\|y-x_k\| \leq r$ for infinitely many k, then $\|y-x\| \leq r$; so $\limsup_k \mathbf{1}_{\overline{B}(x_k,r)} \leq \mathbf{1}_{\overline{B}(x,r)}$, and Fatou's lemma applied to the non-negative functions $\mathbf{1}_{\overline{B}(x,r+1)} - \mathbf{1}_{\overline{B}(x_k,r)}$ (k large), whose integrals are finite, gives $\limsup_k \mu(\overline{B}(x_k,r)) \leq \mu(\overline{B}(x,r))$. The spheres of different radii are disjoint; those of radius less than R with measure at least $1/m$ number at most $m\mu(B(x,R))$, so only countably many spheres have positive measure. □

Exercise 28.23.17. Show directly from Example 28.17.6(2), without Theorem 28.18.10, that the Cantor set has box-counting dimension $\log 2/\log 3$.

Solution. Let $3^{-k-1} \leq \delta < 3^{-k}$. The 2^{k+1} intervals of generation $k+1$ have length $3^{-k-1} \leq \delta$ and cover C, so $N_\delta(C) \leq 2^{k+1}$. A set of diameter at most $\delta < 3^{-k}$ meets at most one of the 2^k intervals of generation k, and each of them contains points of C, so $N_\delta(C) \geq 2^k$. Since $k\log 3 < -\log\delta \leq (k+1)\log 3$,

$$\frac{k\log 2}{(k+1)\log 3} \leq \frac{\log N_\delta(C)}{-\log\delta} \leq \frac{(k+1)\log 2}{k\log 3} \qquad (k \geq 1),$$

and both bounds tend to $\log 2/\log 3$ as $\delta \to 0$, that is, as $k \to \infty$. □

Exercise 28.23.18. Let C be the Cantor set. Show that $C + C = \{x+y : x, y \in C\}$ is the interval $[0,2]$. (Hint: $C \times C$ is the attractor of Example 28.18.11(3); project it as in Example 28.18.12.) So the set $C \times C$, of dimension $\log 4/\log 3 < 2$, has a projection of positive length, while its projections to the axes are copies of C, of length 0.

Solution. Let $\pi(x,y) = x + y$ and $f_{a,b}(x,y) = (x/3 + a, y/3 + b)$ for $a, b \in \{0, \frac{2}{3}\}$. Then $\pi \circ f_{a,b} = g_{a+b} \circ \pi$ with $g_c(t) = t/3 + c$, and $a + b$ takes the values $0, \frac{2}{3}, \frac{4}{3}$. Since $C \times C = \bigcup_{a,b} f_{a,b}(C \times C)$, its image $\pi(C \times C) = C + C$ is a nonempty compact set with $C + C = g_0(C + C) \cup g_{2/3}(C + C) \cup g_{4/3}(C + C)$, that is, the attractor of $\{g_0, g_{2/3}, g_{4/3}\}$. The interval $[0,2]$ is also invariant: $g_0([0,2]) \cup g_{2/3}([0,2]) \cup g_{4/3}([0,2]) = [0, \frac{2}{3}] \cup [\frac{2}{3}, \frac{4}{3}] \cup [\frac{4}{3}, 2]$. By the uniqueness in Theorem 28.18.5, $C + C = [0,2]$. (More generally, by Marstrand's projection theorem a Borel set $A \subseteq \mathbb{R}^2$ with $\dim_{\mathcal{H}} A > 1$ has projections of positive length in almost every direction [Mat95].) □

Exercise 28.23.19. Show that for every $s \in [0,1]$ there is a compact set $K \subseteq [0,1]$ with $\dim_{\mathcal{H}} K = s$ and $0 < \mathcal{H}^s(K) < \infty$.

Solution. For $s = 0$ take a point, for $s = 1$ the interval $[0,1]$ (Theorem 28.17.5). For $0 < s < 1$ let $\rho = 2^{-1/s}$, so $0 < \rho < \frac{1}{2}$, and consider $f_1(x) = \rho x$, $f_2(x) = \rho x + 1 - \rho$. Since $f_1([0,1]) \cup f_2([0,1]) = [0,\rho] \cup [1-\rho, 1] \subseteq [0,1]$, the attractor K lies in $[0,1]$ (Theorem 28.18.5(1)), and the pieces $f_1(K) \subseteq [0,\rho]$ and $f_2(K) \subseteq [1-\rho, 1]$ are disjoint because $\rho < 1 - \rho$. The similarity dimension solves $2\rho^t = 1$, so it is s, and Theorem 28.18.10 applies. □

Exercise 28.23.20. Let K be the attractor of an iterated function system satisfying the strong separation condition, with similarity dimension s, and let μ be the measure constructed in the proof of Theorem 28.18.10.

1. Show that $\mathcal{H}^s(K_w) = r_w^s \mathcal{H}^s(K)$ for every word w, and explain why this, together with $0 < \mathcal{H}^s(K) < \infty$, forces (28.2).

2. Show that two Borel probability measures on K which agree on all the sets K_w are equal. Deduce that $\mu(B) = \mathcal{H}^s(B)/\mathcal{H}^s(K)$ for every Borel set $B \subseteq K$.

Solution. (1) f_w is a similarity with ratio r_w, so $\mathcal{H}^s(f_w(K)) = r_w^s \mathcal{H}^s(K)$. The sets $K_1, \dots, K_N$ are disjoint compact sets with union K, so $\mathcal{H}^s(K) = \sum_i \mathcal{H}^s(K_i) = \left(\sum_i r_i^s\right)\mathcal{H}^s(K)$, and dividing by $\mathcal{H}^s(K) \in (0, \infty)$ gives $\sum_i r_i^s = 1$. This is the heuristic of the introduction to Section 28.18.

(2) Let $\mathcal{P}$ consist of $\emptyset$ and the sets K_w, including $K = K_\varnothing$. Two of the K_w are either nested (if one word begins with the other, by Theorem 28.18.5(2)) or disjoint (if the words first differ at some position, by Step 1 of the proof of Theorem 28.18.10), so $\mathcal{P}$ is closed under finite intersections. Every relatively open $G \subseteq K$ is a countable union of sets $K_w \subseteq G$: if $x \in G$ has address ω, then $x \in K_{\omega|k}$ and $\operatorname{diam} K_{\omega|k} \le r^k \operatorname{diam} K$, so $K_{\omega|k} \subseteq G$ for k large; and there are only countably many words. So $\sigma(\mathcal{P})$ contains the open subsets of K, hence all Borel subsets, and Lemma 28.3.10 shows that two probability measures agreeing on $\mathcal{P}$ agree on all Borel sets. Finally, $B \mapsto \mathcal{H}^s(B)/\mathcal{H}^s(K)$ is a Borel probability measure on K (Proposition 28.17.3(1) and Theorem 28.18.10) which by (1) gives the value $r_w^s = \mu(K_w)$ to every K_w. □

Exercise 28.23.21. Let S be the Sierpiński gasket of a triangle T with perimeter P (Example 28.18.7(3)). Show:

1. $\lambda^2(S) = 0$;

2. two distinct triangles $f_v(T)$, $f_w(T)$ with $|v| = |w|$ meet in at most one point;

3. S contains the boundary ∂T, and more generally the boundaries of all triangles $f_w(T)$;

4. $\mathcal{H}^1(S) = \infty$, so that $1 \le \dim_{\mathcal{H}} S \le \log 3/\log 2$.

Solution. (1) $F^k(T)$ is the union of the 3^k triangles $f_w(T)$, $|w| = k$, which are images of T under similarities of ratio 2^{-k}, so of area $4^{-k}\lambda^2(T)$ (Proposition 28.17.3(3) and Theorem 28.17.5). Hence $\lambda^2(S) \le \lambda^2(F^k(T)) \le (\frac{3}{4})^k \lambda^2(T) \to 0$.

(2) For $i \ne j$ the corner triangles $f_i(T)$ and $f_j(T)$ meet only in the midpoint of the side $p_i p_j$. If $v \ne w$ first differ at position j and u is their common beginning of length $j-1$, then $f_v(T) \subseteq f_u(f_{v_j}(T))$ and $f_w(T) \subseteq f_u(f_{w_j}(T))$, and these meet in the image under the injective map f_u of a single point.

(3) The side $[p_i, p_j]$ is the union of $[p_i, m]$ and $[m, p_j]$, m its midpoint, which are sides of $f_i(T)$ and $f_j(T)$. So $\partial T \subseteq F(\partial T)$, and inductively $\partial T \subseteq F(\partial T) \subseteq F^2(\partial T) \subseteq \cdots$, since F preserves inclusions. As $F^k(\partial T) \subseteq F^k(T)$, $\partial T \subseteq \bigcap_k F^k(T) = S$ (Theorem 28.18.5(1)). Then $f_w(\partial T) \subseteq f_w(S) \subseteq S$.

(4) A segment of length ℓ is isometric to an interval, so it has $\mathcal{H}^1$-measure ℓ (Theorem 28.17.5). By (3), S contains the boundaries of the 3^k triangles of generation k, each the union of three segments of total length $2^{-k}P$. By (2) these 3^{k+1} segments meet each other only in finitely many points, which are $\mathcal{H}^1$-null; so, $\mathcal{H}^1$ being a measure on Borel sets, $\mathcal{H}^1(S) \ge 3^k 2^{-k} P = (\frac{3}{2})^k P$ for every k. Hence $\mathcal{H}^1(S) = \infty$ and $\dim_{\mathcal{H}} S \ge 1$; the upper bound is Proposition 28.18.9, with $3 \cdot 2^{-s} = 1$. (By Remark 28.18.13, $\dim_{\mathcal{H}} S = \log 3/\log 2$.) □

Exercise 28.23.22. Let $h\colon [0,1] \to \mathbb{R}$ satisfy $|h(x) - h(y)| \le c|x-y|^\alpha$ for some $c > 0$ and $0 < \alpha \le 1$ (a *Hölder continuous* function), and let $G = \{(x, h(x)) : x \in [0,1]\}$ be its graph. Show that $1 \le \dim_{\mathcal{H}} G \le \overline{\dim}_B G \le 2 - \alpha$.

Solution. Projection to the first coordinate is 1-Lipschitz and maps G onto $[0,1]$, so $\mathcal{H}^1(G) \geq 1$ and $\dim_{\mathcal{H}} G \geq 1$. For $m \geq 1$ divide $[0,1]$ into m intervals I_j of length $\frac{1}{m}$. On I_j the values of h lie in an interval of length at most $cm^{-\alpha}$, which is covered by at most $cm^{1-\alpha}+1$ intervals of length $\frac{1}{m}$; so the part of G over I_j is covered by at most $cm^{1-\alpha}+1$ squares of side $\frac{1}{m}$, and G by at most $m(cm^{1-\alpha}+1) \leq (c+1)m^{2-\alpha}$ of them. The squares have diameter $\sqrt{2}/m$. Given $0 < \delta < \sqrt{2}$, choose m with $\sqrt{2}/(m+1) \leq \delta < \sqrt{2}/m$; then $N_\delta(G) \leq (c+1)(m+1)^{2-\alpha}$ and $-\log\delta > \log(m/\sqrt{2})$, so

$$\frac{\log N_\delta(G)}{-\log\delta} \leq \frac{\log(c+1)+(2-\alpha)\log(m+1)}{\log m - \log\sqrt{2}} \to 2-\alpha \qquad (\delta \to 0).$$

The middle inequality is Proposition 28.18.2(3). For $\alpha = 1$, a Lipschitz function, the graph has dimension 1, in accordance with Exercise 28.23.9; rough functions can have graphs of dimension close to 2. □

Exercise 28.23.23. Let $g\colon \mathbb{R}^n \to \mathbb{R}$ be continuous, $n \geq 2$, and $\Phi(R) = \int_{B(0,R)} g\, d\lambda^n$. Show that Φ is differentiable on $(0,\infty)$ with $\Phi'(R) = \int_{|x|=R} g\, d\mathcal{H}^{n-1}$, and that the averages $\frac{1}{n\omega_n R^{n-1}} \int_{|x|=R} g\, d\mathcal{H}^{n-1}$ tend to $g(0)$ as $R \to 0$.

Solution. Apply Corollary 28.21.3 to the positive and negative parts of $g\mathbf{1}_{B(0,R)}$, which are bounded Borel functions vanishing outside a bounded set; subtracting, $\Phi(R) = \int_0^R \eta(r)\, dr$ with $\eta(r) = r^{n-1}\int_{S^{n-1}} g(r\theta)\, d\mathcal{H}^{n-1}(\theta)$. As $r \to r_0$, $g(r\theta) \to g(r_0\theta)$ uniformly in $\theta \in S^{n-1}$, by uniform continuity of g on a compact ball, and $\mathcal{H}^{n-1}(S^{n-1}) = n\omega_n < \infty$; so η is continuous on $[0,\infty)$, and $\Phi'(R) = \eta(R)$ by the fundamental theorem of calculus (Theorem 27.8.3). By the scaling in the proof of Corollary 28.21.3, $\eta(R) = \int_{|x|=R} g\, d\mathcal{H}^{n-1}$. Finally $\eta(R)/(n\omega_n R^{n-1}) - g(0) = \frac{1}{n\omega_n}\int_{S^{n-1}} (g(R\theta)-g(0))\, d\mathcal{H}^{n-1}(\theta)$, which is at most $\sup_{|x|=R}|g(x)-g(0)| \to 0$ in absolute value. □

Exercise 28.23.24. (*Dirichlet's approximation theorem.*) Let $x \in \mathbb{R}$ and $N \geq 1$. Using the pigeonhole principle for the $N+1$ numbers $kx - \lfloor kx\rfloor \in [0,1)$, $k = 0,\dots,N$, show that there are integers p, q with $1 \leq q \leq N$ and $|qx - p| < 1/N$. Deduce that an irrational x has infinitely many approximations p/q with $|x - p/q| < 1/q^2$.

Solution. Divide $[0,1)$ into the N intervals $[\frac{i}{N}, \frac{i+1}{N})$. Two of the $N+1$ numbers, for $k < l$ say, lie in the same interval, so $|(l-k)x - (\lfloor lx\rfloor - \lfloor kx\rfloor)| < 1/N$; take $q = l-k$ and $p = \lfloor lx\rfloor - \lfloor kx\rfloor$. Then $|x - p/q| < 1/(qN) \leq 1/q^2$, and also $|x-p/q| < 1/N$. Writing p/q in lowest terms p'/q' with $q' \leq q$ keeps $|x - p'/q'| < 1/q^2 \leq 1/q'^2$. If x is irrational, no fraction equals x, so a finite set of fractions has positive minimal distance from x; since letting $N \to \infty$ produces fractions arbitrarily close to x, we obtain infinitely many distinct ones. □

Exercise 28.23.25. For $x \in [0,1)$ let $e_k(x) = \lfloor 10^k x\rfloor - 10\lfloor 10^{k-1}x\rfloor$ be its decimal digits. Show that for almost every x:

1. every finite block of decimal digits occurs infinitely often among the $e_k(x)$;
2. the frequency $\frac{1}{n}\#\{k \leq n : e_k(x) = 7\}$ tends to $\frac{1}{10}$.

Solution. The analogue of Lemma 28.7.4 holds with the same proof: prescribing the digits at the positions of a finite set S defines a set of measure $10^{-|S|}$, a union of decimal intervals of length 10^{-K}, $K = \max S$, and events determined by disjoint sets of positions are independent, with the product formula for integrals. (1) is then proved as in Example 28.7.7, with probability 10^{-m} for a block of length m. For (2) let $\rho_k = \mathbf{1}_{\{e_k=7\}} - \frac{1}{10}$, so $\int \rho_k = 0$ and $|\rho_k| \leq 1$,

and $S_n = \rho_1 + \cdots + \rho_n$. In $\int S_n^4 = \sum \int \rho_i\rho_j\rho_k\rho_l$, a term in which some index occurs exactly once vanishes by the product formula. The remaining terms have all indices equal (n terms) or two values each occurring twice ($3n(n-1)$ terms), and each is at most 1 in absolute value; so $\int S_n^4 \le 3n^2$, and Step 2 of the proof of Theorem 28.7.9 applies verbatim. □

Exercise 28.23.26. Let $L(F) = F_1(0) + 2F_2(0)$ for $F = (F_1, F_2) \in C_c(\mathbb{R}, \mathbb{R}^2)$. Find the measure μ and the field ν of Theorem 28.14.9, and check (28.1) directly.

Solution. $L(F) = \langle F(0), (1,2)\rangle$, so $L(F) = \int \langle F, \nu\rangle \, d\mu$ with $\mu = \sqrt{5}\,\delta_0$ and $\nu(0) = (1,2)/\sqrt{5}$, a unit vector. For an open $V \ni 0$ and $|F| \le 1$ with support in V, the Cauchy–Schwarz inequality gives $L(F) \le |(1,2)| = \sqrt{5}$, with equality when $F(0) = (1,2)/\sqrt{5}$, which is possible for $F = \psi\,(1,2)/\sqrt{5}$ with $\psi \prec V$, $\psi(0) = 1$; for $0 \notin V$ the supremum is 0. So the total variation is $\sqrt{5}\,\delta_0$, not $\delta_0 + 2\delta_0 = 3\delta_0$: the components cannot be estimated separately, as $|F| \le 1$ couples them. □

Exercise 28.23.27. Show that the intersection of the two solid cylinders $\{x^2 + y^2 \le R^2\}$ and $\{x^2 + z^2 \le R^2\}$ in $\mathbb{R}^3$ (the *Steinmetz solid*) has volume $\frac{16}{3}R^3$, using Cavalieri's principle with slices perpendicular to the x-axis.

Solution. For $|x| \le R$ the slice is $\{(y,z) : |y| \le \sqrt{R^2 - x^2}, |z| \le \sqrt{R^2 - x^2}\}$, a square of side $2\sqrt{R^2 - x^2}$, and it is empty for $|x| > R$. By Proposition 28.11.5 the volume is $\int_{-R}^{R} 4(R^2 - x^2)\,dx = 4\big(2R^3 - \frac{2}{3}R^3\big) = \frac{16}{3}R^3$. (Archimedes knew this too; compare with the ball inscribed in the solid, whose slices are the inscribed discs, of area $\frac{\pi}{4}$ times that of the squares, and whose volume is $\frac{\pi}{4}\cdot\frac{16}{3}R^3 = \frac{4}{3}\pi R^3$.) □

Exercise 28.23.28. Use the Pappus–Guldin theorems to compute the volume and the lateral area of the cone of revolution with base radius R and height h, obtained by rotating the triangle with vertices $(0,0)$, $(R,0)$, $(0,h)$ of the (r,z)-plane around the z-axis. (The centroid of a triangle is the average of its vertices.)

Solution. The triangle has area $\frac{1}{2}Rh$ and centroid at distance $\bar r = \frac{1}{3}(0 + R + 0) = \frac{R}{3}$ from the axis, so the volume is $2\pi\frac{R}{3}\cdot\frac{1}{2}Rh = \frac{1}{3}\pi R^2 h$, by Corollary 28.11.8. The lateral surface comes from the segment from $(R,0)$ to $(0,h)$, of length $\sqrt{R^2 + h^2}$, whose centroid is its midpoint, at distance $\frac{R}{2}$; by Proposition 28.20.6 the area is $2\pi\frac{R}{2}\sqrt{R^2 + h^2} = \pi R\sqrt{R^2 + h^2}$. (That the centroid of a triangle is the average of its vertices follows by applying an affine map taking it to the triangle $(0,0)$, $(1,0)$, $(0,1)$, which changes all areas by the same factor, and computing $\int_0^1 \int_0^{1-r} r\,dz\,dr = \frac{1}{6} = \frac{1}{3}\cdot\frac{1}{2}$.) □

Exercise 28.23.29. Compute the volume of the solid obtained by rotating the region $\{(r,z) : 0 < r \le \pi, 0 \le z \le \sin r\}$ around the z-axis, using shells, and check the result with the Pappus–Guldin theorem.

Solution. By Proposition 28.11.7(2), with $a \to 0$ by monotone convergence, the volume is $2\pi\int_0^\pi r\sin r\,dr = 2\pi\big[\sin r - r\cos r\big]_0^\pi = 2\pi^2$. The region has area $\int_0^\pi \sin r\,dr = 2$, and by symmetry about $r = \frac{\pi}{2}$ its centroid has $\bar r = \frac{\pi}{2}$; indeed $2\pi\cdot\frac{\pi}{2}\cdot 2 = 2\pi^2$. □

Exercise 28.23.30. Show that the solid paraboloid $\{(x,y,z) : x^2 + y^2 \le z \le h\}$ has half the volume of the circumscribed cylinder $\{x^2 + y^2 \le h, 0 \le z \le h\}$, a result of Archimedes.

Solution. By the disc method with $f(z) = \sqrt{z}$ on $[0,h]$, the volume is $\pi\int_0^h z\,dz = \frac{1}{2}\pi h^2$, and the cylinder of radius $\sqrt{h}$ and height h has volume $\pi h\cdot h = \pi h^2$. □

Chapter 29

Complex Analysis

29.1 Introduction

A function of one complex variable that is differentiable once is analytic, and is determined by its values on any set with a limit point. This rigidity, which has no analogue in real analysis, is the source of the special features of complex geometry: on a compact complex manifold there are few holomorphic functions, and the interplay between holomorphic and topological invariants leads to Hodge theory. This chapter proves Cauchy's theorem in homotopy form (Theorem 29.3.3), the Cauchy integral formula and its consequences, the residue theorem, and the Riemann mapping theorem (Theorem 29.6.5). The last section studies the Riemann sphere $\hat{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$: stereographic projection, the rational functions as the meromorphic functions on $\hat{\mathbb{C}}$ (Theorem 29.7.5), and the Möbius transformations, with the cross-ratio and their classification into parabolic, elliptic, hyperbolic and loxodromic ones (Theorem 29.7.14). References: [Ahl78], [SS03], [Con78] and [Rud87, Chapters 10–16].
Prerequisites. Chapter 27 (Real Analysis) and Chapter 19 (Homotopy and Covering Spaces).
On the way to the Hodge conjecture. Needed: holomorphic functions, Cauchy's theorem and the Cauchy integral formula, and Laurent series and residues. The Riemann mapping theorem and the Riemann sphere (Sections 29.6, 29.7) can be postponed.

We write $D(a, r) = \{z : |z - a| < r\}$, $\overline{D}(a, r)$ for its closure, and $\mathbb{D} = D(0, 1)$. All domains (= nonempty connected open subsets of $\mathbb{C}$) are denoted U, V.

29.2 Holomorphic functions

Definition 29.2.1. Let $U \subseteq \mathbb{C}$ be open. A function $f : U \to \mathbb{C}$ is *holomorphic* if the limit $f'(a) = \lim_{h \to 0}(f(a + h) - f(a))/h$, $h \in \mathbb{C}^\times$, exists for every $a \in U$. An *entire* function is one holomorphic on $\mathbb{C}$.

The definition looks exactly like the one for real functions, but h now tends to 0 through all complex numbers, from every direction at once, and the difference quotient must have the same limit along all of them. This single requirement turns out to be extraordinarily strong: it implies that f has derivatives of all orders and is given by its Taylor series (Theorem 29.4.2 and Corollary 29.4.3). Before seeing why, let us compute a few derivatives directly from the definition.

Example 29.2.2. Let $a \in \mathbb{C}$ and $h \in \mathbb{C}^\times$ small.

1. $f(z) = z^n$, $n \geq 1$. By the binomial theorem $(a + h)^n - a^n = na^{n-1}h + \sum_{k=2}^{n} \binom{n}{k} a^{n-k}h^k$, so the difference quotient is $na^{n-1} + \sum_{k=2}^{n} \binom{n}{k} a^{n-k}h^{k-1} \to na^{n-1}$. So $(z^n)' = nz^{n-1}$, as over $\mathbb{R}$.

2. $f(z) = 1/z$ on $\mathbb{C}^\times$. For $a \neq 0$ and $|h| < |a|$, $\frac{1}{h}\left(\frac{1}{a+h} - \frac{1}{a}\right) = \frac{-1}{a(a+h)} \to -\frac{1}{a^2}$.

3. $f(z) = \bar{z}$. The difference quotient is $\bar{h}/h$, which equals 1 for real h and -1 for purely imaginary h. So the limit exists at no point: $\bar{z}$ is a perfectly smooth map of the plane, an isometry even, but it is nowhere complex differentiable. The same happens for $\operatorname{Re} z$, whose quotient $\operatorname{Re} h/h$ is 1 on the real axis and 0 on the imaginary axis.

4. $f(z) = |z|^2 = z\bar{z}$. Here $|a+h|^2 - |a|^2 = \bar{a}h + a\bar{h} + |h|^2$, so the quotient is $\bar{a} + a\,\bar{h}/h + \bar{h}$. For $a = 0$ it is $\bar{h} \to 0$; for $a \neq 0$ the middle term $a\,\bar{h}/h$ has no limit, by (3). So $|z|^2$ is complex differentiable at 0 and nowhere else. A function can be complex differentiable at a single point; "holomorphic" asks for it at every point of an open set, and all the theory below depends on this.

Proposition 29.2.3 (Cauchy–Riemann)**.** *Identify $\mathbb{C}$ with $\mathbb{R}^2$ and write $f = u + iv$. Then f is holomorphic at a if and only if f is differentiable at a as a map of real variables (Definition 27.10.2) and its derivative is complex linear, which holds if and only if*

$$\partial_x u = \partial_y v, \qquad \partial_y u = -\partial_x v \quad \text{at } a.$$

Then $f'(a) = \partial_x u + i\partial_x v$. Sums, products, quotients and composites of holomorphic functions are holomorphic, with the usual rules.

Proof. Complex differentiability at a says $f(a+h) = f(a) + ch + o(|h|)$ with $c = f'(a) \in \mathbb{C}$, which is real differentiability with $Df(a)$ the real linear map $h \mapsto ch$, that is, with matrix $\left(\begin{smallmatrix} \alpha & -\beta \\ \beta & \alpha \end{smallmatrix}\right)$ for $c = \alpha + i\beta$. Comparing with the Jacobian matrix $\left(\begin{smallmatrix} \partial_x u & \partial_y u \\ \partial_x v & \partial_y v \end{smallmatrix}\right)$ gives the equations. The rules follow as in Proposition 27.6.2, whose proofs are valid over $\mathbb{C}$. □

Example 29.2.4. Polynomials are entire; $1/z$ is holomorphic on $\mathbb{C}^\times$; power series are holomorphic in their disc of convergence, with the termwise derivative (Theorem 27.6.20); exp is entire with $\exp' = \exp$. The function $\bar{z}$ is nowhere holomorphic, since $\partial_x u = 1 \neq -1 = \partial_y v$.

The Cauchy–Riemann equations have a geometric meaning. A real linear map $\mathbb{R}^2 \to \mathbb{R}^2$ is complex linear exactly when its matrix is $\left(\begin{smallmatrix} \alpha & -\beta \\ \beta & \alpha \end{smallmatrix}\right)$, that is, when it is multiplication by $c = \alpha + i\beta = |c|e^{i\varphi}$: a rotation by φ followed by a dilation by $|c|$. So near a point where $f'(a) \neq 0$, a holomorphic map looks, to first order, like a rotation and a dilation, which preserve angles and orientation. Maps with this property are called *conformal*, and the converse also holds.

Proposition 29.2.5. *1. Let f be holomorphic near a with $f'(a) \neq 0$, and let γ_1, γ_2 be C^1 curves with $\gamma_1(0) = \gamma_2(0) = a$ and nonzero tangent vectors $\gamma_1'(0), \gamma_2'(0)$. Then $(f \circ \gamma_j)'(0) = f'(a)\gamma_j'(0)$. Hence the image curves have tangent vectors rotated by the same angle $\arg f'(a)$ and stretched by the same factor $|f'(a)|$, and the oriented angle between them equals that between γ_1 and γ_2.*

2. Conversely, let f be real differentiable at a with $A = Df(a)$ invertible, and suppose that A preserves oriented angles, that is, Aw/Av and w/v have the same argument for all nonzero $v, w \in \mathbb{C}$. Then f is complex differentiable at a.

Proof. (1) By the chain rule (Proposition 27.6.2) and Proposition 29.2.3, $(f \circ \gamma_j)'(0) = Df(a)\gamma_j'(0) = f'(a)\gamma_j'(0)$. The quotient of the two image tangent vectors is $\gamma_2'(0)/\gamma_1'(0)$, the same as for the original ones, and the oriented angle from one vector to another is the argument of this quotient.

(2) Let $p = A(1) \neq 0$ and $q = A(i)$. The oriented angle from 1 to i is $\frac{\pi}{2}$, so q/p has argument $\frac{\pi}{2}$: $q = itp$ for some $t > 0$. The oriented angle from 1 to $1 + i$ is $\frac{\pi}{4}$, so $A(1 + i)/A(1) = (p + q)/p = 1 + it$ has argument $\frac{\pi}{4}$, which forces $t = 1$. Hence $A(x + iy) = xp + yip = (x + iy)p$: A is multiplication by p, so it is complex linear, and f is complex differentiable at a with $f'(a) = p$ by Proposition 29.2.3. □

Example 29.2.6.

1. *Critical points.* For $f(z) = z^2$ and $a = 0$, where $f'(0) = 0$, angles are not preserved but doubled: the ray $\{re^{i\theta} : r > 0\}$ is mapped to the ray $\{r^2 e^{2i\theta}\}$. In general, near a zero of order m of f' the map multiplies angles by $m + 1$; this follows from the local form of holomorphic maps (Theorem 29.5.12).

2. *The exponential.* $e^{x+iy} = e^x e^{iy}$ maps the vertical line $x = x_0$ onto the circle of radius e^{x_0}, and the horizontal line $y = y_0$ onto the ray of argument y_0. The lines of the grid meet at right angles, and so do their images, circles and rays from the origin, as Proposition 29.2.5 predicts, since $\exp' = \exp$ never vanishes.

3. *Reflection.* $z \mapsto \bar{z}$ preserves the size of angles but reverses their orientation, and it is not holomorphic (Example 29.2.2(3)). The argument in (2) adapts: an invertible real linear map that preserves unoriented angles is either complex linear or of the form $z \mapsto p\bar{z}$, so the maps that preserve unoriented angles, at points where the derivative is invertible, are the holomorphic and the *antiholomorphic* ones (those f with $\bar{f}$ holomorphic).

Definition 29.2.7. A *path* is a piecewise continuously differentiable map $\gamma\colon [a, b] \to \mathbb{C}$; it is *closed* if $\gamma(a) = \gamma(b)$. Its image is γ^* and its length is $L(\gamma) = \int_a^b |\gamma'(t)|\, dt$. For continuous f on γ^*,

$$\int_\gamma f(z)\, dz = \int_a^b f(\gamma(t))\gamma'(t)\, dt.$$

Lemma 29.2.8. *The integral is unchanged by increasing C^1 reparametrisations, changes sign under reversal, and $|\int_\gamma f| \leq L(\gamma) \sup_{\gamma^*} |f|$. If $f = F'$ for a holomorphic F on an open set containing γ^*, then $\int_\gamma f = F(\gamma(b)) - F(\gamma(a))$; in particular $\int_\gamma f = 0$ for closed γ. For the circle $\gamma(t) = a + re^{2\pi it}$, $t \in [0, 1]$, one has $\int_\gamma (z - a)^n\, dz = 0$ for $n \neq -1$ and $= 2\pi i$ for $n = -1$.*

Proof. Reparametrisation and reversal follow from the substitution rule (Corollary 27.8.4), the estimate from Proposition 27.8.2. If $f = F'$, then $(F \circ \gamma)' = f(\gamma)\gamma'$ on each C^1 piece, so the integral telescopes by the fundamental theorem of calculus. For the circle and $n \neq -1$, $(z - a)^n$ has the primitive $(z - a)^{n+1}/(n + 1)$; for $n = -1$ the integral is $\int_0^1 2\pi i\, dt$. □

In the definition, $f(\gamma(t))\gamma'(t)$ is a complex-valued function of the real variable t, and its integral is taken separately on the real and the imaginary part (Definition 27.8.1): $\int_a^b (g + ih) = \int_a^b g + i \int_a^b h$. So a complex line integral is a pair of real line integrals, and the formal rule $f\, dz = (u + iv)(dx + i\, dy)$ says which ones.

Proposition 29.2.9. *Let $\gamma = x + iy$ be a path and $f = u + iv$ continuous on γ^*, with x, y, u, v real. Then*

$$\int_\gamma f(z)\, dz = \int_\gamma (u\, dx - v\, dy) + i \int_\gamma (v\, dx + u\, dy),$$

where the two integrals on the right are real line integrals of the second kind (Definition 27.11.12) of the vector fields $(u, -v)$ and (v, u) in $\mathbb{R}^2 = \mathbb{C}$. Moreover $\left|\int_\gamma f(z)\, dz\right| \leq \int_\gamma |f|\, ds$, where $\int_\gamma |f|\, ds = \int_a^b |f(\gamma(t))|\,|\gamma'(t)|\, dt$ is a line integral of the first kind (Definition 27.11.9), also written $\int_\gamma |f|\,|dz|$.

Proof. On each C^1 piece, $f(\gamma(t))\gamma'(t) = (u+iv)(x'+iy') = (ux'-vy')+i(vx'+uy')$, with u and v evaluated at $\gamma(t)$. The real part is $\langle (u,-v),(x',y')\rangle$ and the imaginary part $\langle (v,u),(x',y')\rangle$, and integrating them gives the two line integrals. The estimate is the norm inequality $|\int g| \le \int |g|$ of Proposition 27.8.2(3), since $|f(\gamma(t))\gamma'(t)| = |f(\gamma(t))|\,|\gamma'(t)|$. □

For instance, for $f(z) = \bar{z} = x - iy$ the two real fields are (x,y) and $(-y,x)$. The first is the gradient of $\frac{1}{2}(x^2+y^2)$, so its integral over a closed path vanishes; the second is the rotation field, whose integral over the unit circle is 2π (Example 27.11.14(1)). This gives $\int_\gamma \bar{z}\,dz = 0 + 2\pi i$, as in Example 29.2.11(1) below.

Remark 29.2.10. The two real forms are closed exactly when f satisfies the Cauchy–Riemann equations: for u, v of class C^1, $d(u\,dx - v\,dy) = -(u_y + v_x)\,dx \wedge dy$ and $d(v\,dx + u\,dy) = (u_x - v_y)\,dx \wedge dy$ (Proposition 29.2.3). So, if f is holomorphic with continuous derivative and γ bounds a region D in its domain, Green's theorem (Chapter 40) gives $\int_\gamma f\,dz = \iint_D 0 = 0$: this is Cauchy's original proof of his theorem. The proof below, through Goursat's theorem, does not assume that f' is continuous, and does not need Green's theorem. In the language of Chapter 36, $f\,dz$ is a complex-valued 1-form, and $d(f\,dz) = \frac{\partial f}{\partial \bar{z}}\,d\bar{z} \wedge dz$, which vanishes for holomorphic f.

Example 29.2.11.

1. *A function without primitive.* Let $\gamma(t) = e^{2\pi i t}$, $t \in [0,1]$, be the unit circle. On it $\bar{z} = e^{-2\pi i t}$ and $\gamma'(t) = 2\pi i e^{2\pi i t}$, so $\int_\gamma \bar{z}\,dz = \int_0^1 2\pi i\,dt = 2\pi i \neq 0$. By Lemma 29.2.8, $\bar{z}$ is not the derivative of a holomorphic function on any open set containing the circle.

2. *Dependence on the path.* Integrate $\bar{z}$ from 0 to $1+i$ in two ways. Along the segment $\gamma(t) = t(1+i)$: $\int_0^1 t(1-i)(1+i)\,dt = \int_0^1 2t\,dt = 1$. Along the segment from 0 to 1 followed by the segment from 1 to $1+i$, parametrised by t and $1+it$: $\int_0^1 t\,dt + \int_0^1 (1-it)\,i\,dt = \frac{1}{2} + \left(i + \frac{1}{2}\right) = 1+i$. The results differ. For a function with a primitive, such as $z^2 = (z^3/3)'$, every path from 0 to $1+i$ gives $(1+i)^3/3$.

3. *A holomorphic function without primitive.* $1/z$ is holomorphic on $\mathbb{C}^\times$, yet $\int_\gamma dz/z = 2\pi i$ over the unit circle (Lemma 29.2.8); so $1/z$ has no primitive on $\mathbb{C}^\times$, that is, there is no holomorphic logarithm on $\mathbb{C}^\times$. What goes wrong is the hole at 0: Cauchy's theorem below says that integrals of holomorphic functions over closed paths vanish when the path can be shrunk to a point inside the domain.

29.3 Cauchy's theorem

Example 29.2.11 shows that integrals over closed paths need not vanish, either because the function is not holomorphic ($\bar{z}$) or because the domain has a hole ($1/z$). Cauchy's theorem says that these are the only obstructions. For a function $f = u + iv$ of class C^1 on a neighbourhood of a triangle T there is a quick argument, using Green's formula $\int_{\partial T}(P\,dx + Q\,dy) = \iint_T (\partial_x Q - \partial_y P)\,dx\,dy$ (proved in Chapter 36 in the language of forms) with $P = f$ and $Q = i f$, since $dz = dx + i\,dy$:

$$\int_{\partial T} f\,dz = \iint_T \left(i\,\partial_x f - \partial_y f\right) dx\,dy = 0,$$

because the Cauchy–Riemann equations say exactly that $\partial_y f = i\,\partial_x f$ (Proposition 29.2.3: $\partial_y f = \partial_y u + i\partial_y v = -\partial_x v + i\partial_x u$). Goursat's theorem proves the same conclusion assuming only that f' exists, without its continuity, by subdividing the triangle and using the linear

approximation of f at one point. This is what later allows us to prove, rather than assume, that holomorphic functions are smooth.

Theorem 29.3.1 (Goursat)**.** *Let U be open, $p \in U$, and $f : U \to \mathbb{C}$ continuous on U and holomorphic on $U \setminus \{p\}$. Then $\int_{\partial T} f = 0$ for every closed triangle $T \subseteq U$, where ∂T is its boundary traversed once.*

Proof. First assume f is holomorphic on all of U. Let $I = \int_{\partial T} f$. Joining the midpoints of the sides divides T into four triangles whose boundary integrals add up to I (the inner edges cancel), so one of them, T_1, has $|\int_{\partial T_1} f| \geq |I|/4$. Iterating gives nested triangles T_n with $\operatorname{diam} T_n = 2^{-n} \operatorname{diam} T$, $L(\partial T_n) = 2^{-n} L(\partial T)$ and $|\int_{\partial T_n} f| \geq 4^{-n}|I|$. Their intersection is a point z_0. Given $\varepsilon > 0$, holomorphy at z_0 gives δ with $|f(z) - f(z_0) - f'(z_0)(z - z_0)| \leq \varepsilon|z - z_0|$ for $|z - z_0| < \delta$. The affine function $f(z_0) + f'(z_0)(z - z_0)$ has a primitive, so its integral over ∂T_n vanishes, and for large n, $|\int_{\partial T_n} f| \leq \varepsilon \operatorname{diam}(T_n) L(\partial T_n) = \varepsilon 4^{-n} \operatorname{diam}(T) L(\partial T)$. Hence $|I| \leq \varepsilon \operatorname{diam}(T) L(\partial T)$ for all ε.

If f is only continuous at p: if $p \notin T$ we are done. If p is a vertex of T, write T as the union of a small triangle T' with vertex p and two triangles not containing p; then $|\int_{\partial T} f| = |\int_{\partial T'} f| \leq L(\partial T') \sup_T |f| \to 0$ as T' shrinks. For general $p \in T$, join p to the vertices. □

Corollary 29.3.2. *Let U be convex, $p \in U$, and f continuous on U and holomorphic on $U \setminus \{p\}$. Then f has a primitive on U, and $\int_\gamma f = 0$ for every closed path γ in U.*

Proof. Fix $z_0 \in U$ and set $F(z) = \int_{[z_0, z]} f$, the integral over the segment. For $z, z + h \in U$, the triangle with vertices $z_0, z, z + h$ lies in U, so $F(z + h) - F(z) = \int_{[z, z+h]} f$ by Theorem 29.3.1. Hence $|F(z + h) - F(z) - f(z)h| \leq |h| \sup_{[z,z+h]} |f - f(z)| = o(|h|)$ by continuity, so $F' = f$. Apply Lemma 29.2.8. □

Theorem 29.3.3 (Cauchy's theorem, homotopy form)**.** *Let f be holomorphic on an open $U \subseteq \mathbb{C}$ and let γ_0, γ_1 be paths in U that are homotopic in U, either as closed paths or with fixed endpoints. Then $\int_{\gamma_0} f = \int_{\gamma_1} f$. In particular $\int_\gamma f = 0$ for every closed path that is null-homotopic in U, and every holomorphic function on a simply connected open set has a primitive.*

Proof. Let $H : [0, 1]^2 \to U$ be the homotopy, $H(s, 0) = \gamma_0(s)$, $H(s, 1) = \gamma_1(s)$. Its image is compact, so there is $\rho > 0$ with $D(H(s, t), \rho) \subseteq U$ for all (s, t), and by uniform continuity there is N with $|H(s, t) - H(s', t')| < \rho$ whenever $|s - s'|, |t - t'| \leq 1/N$. Put $z_{jk} = H(j/N, k/N)$ and let $D_{jk} = D(z_{jk}, \rho)$, so that H maps the square $[j/N, (j + 1)/N] \times [k/N, (k + 1)/N]$ into D_{jk}. Let P_k be the closed polygonal path through $z_{0k}, z_{1k}, \ldots, z_{Nk}$.

Each segment $[z_{jk}, z_{j+1,k}]$ and the corresponding piece of $H(-, k/N)$ lie in the convex set D_{jk}, where f has a primitive by Corollary 29.3.2; so the integrals of f over them agree, and $\int_{\gamma_0} f = \int_{P_0} f$, $\int_{\gamma_1} f = \int_{P_N} f$ (for γ_0, γ_1 piecewise C^1; the intermediate paths are only continuous, and the polygonal paths replace them). The closed polygon with vertices $z_{jk}, z_{j+1,k}, z_{j+1,k+1}, z_{j,k+1}$ lies in the convex set D_{jk}, so the integral of f over it vanishes. Summing over j, the contributions of the segments $[z_{jk}, z_{j,k+1}]$ cancel in pairs (for closed homotopies because $z_{0k} = z_{Nk}$; for fixed endpoints because those segments are constant), so $\int_{P_k} f = \int_{P_{k+1}} f$. Hence $\int_{P_0} f = \int_{P_N} f$. The last statement follows by fixing $z_0 \in U$ and setting $F(z) = \int_\gamma f$ for any path from z_0 to z, which is independent of the path since U is simply connected; then $F' = f$ as in Corollary 29.3.2. □

Definition 29.3.4. For a closed path γ and $a \notin \gamma^*$, the *winding number* is $n(\gamma, a) = \frac{1}{2\pi i} \int_\gamma \frac{dz}{z - a}$.

Proposition 29.3.5. *$n(\gamma, a)$ is an integer; it is constant on connected components of $\mathbb{C} \setminus \gamma^*$ and zero on the unbounded component. Homotopic closed paths in $\mathbb{C} \setminus \{a\}$ have the same winding number about a, and for the circle $\gamma(t) = a + re^{2\pi i t}$ one has $n(\gamma, a) = 1$.*

Proof. Let $\gamma\colon [0,1] \to \mathbb{C}$ and $\varphi(t) = \int_0^t \frac{\gamma'(s)}{\gamma(s)-a}\,ds$. Then $(e^{-\varphi}(\gamma - a))' = 0$ on each C^1 piece, so $e^{\varphi(1)} = (\gamma(1)-a)/(\gamma(0)-a) = 1$ and $\varphi(1) \in 2\pi i\mathbb{Z}$ by Theorem 27.7.3. The function $a \mapsto n(\gamma, a)$ is continuous on $\mathbb{C} \setminus \gamma^*$ and integer valued, hence locally constant, and it tends to 0 as $|a| \to \infty$. Homotopy invariance is Theorem 29.3.3 applied to $z \mapsto 1/(z-a)$ on $\mathbb{C} \setminus \{a\}$, and the circle was computed in Lemma 29.2.8. □

29.4 The Cauchy integral formula

Theorem 29.4.1. *Let U be convex, f holomorphic on U, γ a closed path in U and $a \in U \setminus \gamma^*$. Then*

$$n(\gamma, a) f(a) = \frac{1}{2\pi i} \int_\gamma \frac{f(z)}{z-a}\,dz.$$

In particular, if $\overline{D}(a,r) \subseteq U$ and γ is the circle $\partial D(a,r)$ traversed once, then $f(w) = \frac{1}{2\pi i}\int_\gamma \frac{f(z)}{z-w}dz$ for $w \in D(a,r)$.

Proof. Define $g(z) = (f(z) - f(a))/(z-a)$ for $z \neq a$ and $g(a) = f'(a)$. Then g is continuous on U and holomorphic on $U \setminus \{a\}$, so $\int_\gamma g = 0$ by Corollary 29.3.2. For the second statement, note that $n(\gamma, w) = n(\gamma, a) = 1$ for $w \in D(a,r)$ by Proposition 29.3.5, and apply the formula in the convex set $D(a,r')$ for $r < r'$ with $\overline{D}(a,r') \subseteq U$. □

Theorem 29.4.2. *Let f be holomorphic on an open U and $D(a,R) \subseteq U$. Then $f(w) = \sum_{n\geq 0} c_n (w-a)^n$ on $D(a,R)$, with $c_n = \frac{1}{2\pi i}\int_{\partial D(a,r)} \frac{f(z)}{(z-a)^{n+1}}dz = \frac{f^{(n)}(a)}{n!}$ for any $0 < r < R$. In particular holomorphic functions have holomorphic derivatives of all orders, and $|f^{(n)}(a)| \leq n!\, r^{-n} \sup_{|z-a|=r} |f|$ (*Cauchy estimates*).*

Proof. Fix $|w-a| < r < R$. For $|z-a| = r$, $\frac{1}{z-w} = \sum_{n\geq 0} \frac{(w-a)^n}{(z-a)^{n+1}}$, converging uniformly in z since $|w-a|/r < 1$. Multiplying by $f(z)/2\pi i$ and integrating term by term (uniform convergence, Proposition 27.8.2) gives the expansion with the stated c_n, by Theorem 29.4.1. A power series is infinitely complex differentiable with $c_n = f^{(n)}(a)/n!$ (Theorem 27.6.20), and the estimate follows from Lemma 29.2.8. □

The last statement of Theorem 29.4.2 deserves a closer look, because nothing like it is true for real functions. Definition 29.2.1 only asks that $f'(a)$ exists at every point; it does not ask that f' be continuous. For a function of one real variable this would be a much weaker requirement than being of class C^1: $x^2 \sin(1/x)$, extended by 0 at 0, is differentiable everywhere with a discontinuous derivative, and its antiderivatives are differentiable twice but not three times. For complex differentiability the hierarchy collapses: one derivative gives all of them, and they are all continuous.

Corollary 29.4.3. *Let $f = u + iv$ be holomorphic on an open $U \subseteq \mathbb{C}$, and identify $\mathbb{C}$ with $\mathbb{R}^2$, $z = x + iy$.*

1. *The derivatives $f', f'', \ldots, f^{(k)}, \ldots$ exist and are holomorphic, hence continuous, on U.*
2. *As a function of the two real variables x, y, f is of class C^∞, and for all $a, b \geq 0$*

$$\partial_x^a \partial_y^b f = i^b f^{(a+b)}.$$

In particular u and v are of class C^∞.

3. *u and v are* harmonic*: $\partial_x^2 u + \partial_y^2 u = 0$ and $\partial_x^2 v + \partial_y^2 v = 0$ on U.*

Proof. (1) By Theorem 29.4.2, applied on discs $D(a, R) \subseteq U$, the derivative of a holomorphic function is holomorphic. By induction on k every $f^{(k)}$ exists and is holomorphic. A function that is complex differentiable at a point is continuous there, since $f(a+h) - f(a) = h \cdot (f(a+h) - f(a))/h \to 0 \cdot f'(a) = 0$.

(2) Let g be holomorphic on U. By Proposition 29.2.3, g is real differentiable and $Dg(a)$ is multiplication by $g'(a)$. The partial derivatives are the values of $Dg(a)$ on the basis vectors 1 and i of $\mathbb{R}^2 = \mathbb{C}$:

$$\partial_x g(a) = g'(a) \cdot 1 = g'(a), \qquad \partial_y g(a) = g'(a) \cdot i = i g'(a).$$

So ∂_x and ∂_y map holomorphic functions to holomorphic functions, acting as $g \mapsto g'$ and $g \mapsto ig'$. Applying this $a + b$ times, starting from $g = f$ and using (1), shows that every partial derivative $\partial_x^a \partial_y^b f$ (in any order of differentiation) exists and equals $i^b f^{(a+b)}$, which is continuous by (1). Hence f is C^∞ by definition, and so are its real and imaginary parts $u = \operatorname{Re} f$ and $v = \operatorname{Im} f$, whose partial derivatives are the real and imaginary parts of those of f.

(3) By (2), $\partial_x^2 f + \partial_y^2 f = f'' + i^2 f'' = 0$. The real and imaginary parts of this equation are $\Delta u = 0$ and $\Delta v = 0$, where $\Delta = \partial_x^2 + \partial_y^2$, since ∂_x and ∂_y commute with taking real and imaginary parts. □

Remark 29.4.4. *Where does the regularity come from?* The proof of Corollary 29.4.3 passes through four steps, and it is worth seeing what each one uses.

1. *Goursat's theorem* (Theorem 29.3.1) uses complex differentiability only at a single point z_0 for each triangle, through the linear approximation $f(z) = f(z_0) + f'(z_0)(z - z_0) + o(|z - z_0|)$. No continuity of f' is needed. This is the crucial step: the classical proof of Cauchy's theorem by Green's formula, $\int_{\partial T} f\,dz = \iint_T (\partial_x f + i\partial_y f)\,i\,dx\,dy$, needs f to be of class C^1, and would give the result only for C^1 functions.

2. From vanishing integrals over triangles one gets a primitive on discs (Corollary 29.3.2), and from that the Cauchy integral formula (Theorem 29.4.1), applied to the auxiliary function $g(z) = (f(z) - f(a))/(z - a)$, which is continuous at a and holomorphic elsewhere. This is why Goursat's theorem allows one exceptional point.

3. The Cauchy formula $f(w) = \frac{1}{2\pi i} \int_{|z-a|=r} \frac{f(z)}{z-w}\,dz$ expresses f inside the disc as an average of its values on the circle against the kernel $1/(z - w)$, which is infinitely differentiable in w. All the regularity of the kernel passes to f: one may differentiate under the integral sign, or, as in Theorem 29.4.2, expand the kernel in a geometric series and obtain a power series.

4. Power series are infinitely differentiable (Theorem 27.6.20).

So the equation $\partial f/\partial \bar{z} = 0$ (the Cauchy–Riemann equations, see below) forces smoothness. This is the first instance of *elliptic regularity*: solutions of elliptic differential equations are as smooth as the equation allows, whatever regularity was assumed a priori; Chapter 42 proves this in general, and it is what makes harmonic forms smooth in the Hodge theorem.

It is often convenient to package the two real partial derivatives into the *Wirtinger derivatives*

$$\frac{\partial}{\partial z} = \frac{1}{2}\Big(\partial_x - i\partial_y\Big), \qquad \frac{\partial}{\partial \bar{z}} = \frac{1}{2}\Big(\partial_x + i\partial_y\Big),$$

defined for real differentiable functions. For $f = u + iv$ the real and imaginary parts of $2\,\partial f/\partial\bar z = (\partial_x u - \partial_y v) + i(\partial_x v + \partial_y u)$ are the two Cauchy–Riemann expressions, so a real differentiable f is holomorphic exactly when $\partial f/\partial\bar z = 0$, and then $\partial f/\partial z = f'$. On C^2 functions

$$4\frac{\partial}{\partial z}\frac{\partial}{\partial \bar z} = (\partial_x - i\partial_y)(\partial_x + i\partial_y) = \partial_x^2 + \partial_y^2 = \Delta,$$

since ∂_x and ∂_y commute on C^2 functions (Theorem 27.10.5). This gives a second proof of part (3): $\Delta f = 4\frac{\partial}{\partial z}\big(\frac{\partial f}{\partial \bar z}\big) = 0$. The Wirtinger derivatives satisfy the product rule, and $\partial\bar g/\partial\bar z = \overline{\partial g/\partial z}$, as one checks from the definitions.

Example 29.4.5. 1. From $z^2 = (x^2-y^2) + i\,2xy$, the functions x^2-y^2 and $2xy$ are harmonic; from $e^z = e^x\cos y + ie^x\sin y$, so are $e^x\cos y$ and $e^x\sin y$. The level curves of u and v meet at right angles wherever $f' \neq 0$: by the Cauchy–Riemann equations, $\nabla u = (\partial_x u, \partial_y u)$ and $\nabla v = (-\partial_y u, \partial_x u)$ are orthogonal vectors of the same length $|f'|$.

2. $\log|f|$ *is harmonic where* $f \neq 0$. On a disc $D \subseteq U$ on which f has no zeros, f'/f is holomorphic, so it has a primitive g (Corollary 29.3.2); then $(fe^{-g})' = (f' - fg')e^{-g} = 0$, so $f = ce^g$ with a constant $c = e^{c_0} \neq 0$, and $\log|f| = \operatorname{Re}(g + c_0)$ is harmonic. For example $\log|z| = \frac{1}{2}\log(x^2+y^2)$ is harmonic on $\mathbb{C}^\times$, although it is not the real part of a holomorphic function g on all of $\mathbb{C}^\times$: by the Cauchy–Riemann equations $g' = \partial_x \operatorname{Re} g - i\partial_y \operatorname{Re} g$, which for $\operatorname{Re} g = \log|z|$ is $(x - iy)/(x^2+y^2) = 1/z$, and $1/z$ has no primitive on $\mathbb{C}^\times$, its integral over the unit circle being $2\pi i$ (Lemma 29.2.8).

3. $|f|^2$ *is not harmonic, but subharmonic.* With the product rule, $\frac{\partial}{\partial\bar z}(f\bar f) = f\,\overline{f'}$, because $\partial f/\partial\bar z = 0$ and $\partial\bar f/\partial\bar z = \overline{f'}$; differentiating again, $\frac{\partial}{\partial z}\big(f\,\overline{f'}\big) = f'\,\overline{f'}$, since $\overline{f'}$ has $\partial/\partial z$ equal to $\overline{\partial f'/\partial\bar z} = 0$. Hence $\Delta|f|^2 = 4|f'|^2 \geq 0$. For $f(z) = z$ this is $\Delta(x^2+y^2) = 4$.

Counterexample 29.4.6. The Cauchy–Riemann equations at a point do not imply complex differentiability there; Proposition 29.2.3 also requires real differentiability. Let $f(x+iy) = \sqrt{|xy|}$, so $u = \sqrt{|xy|}$ and $v = 0$. Since u vanishes on both axes, $\partial_x u(0) = \partial_y u(0) = 0$, and the Cauchy–Riemann equations hold at 0. But for $h = t(1+i)$ with $t \in \mathbb{R}^\times$, $(f(h) - f(0))/h = |t|/(t(1+i))$, which is $\frac{1}{1+i}$ for $t > 0$ and $-\frac{1}{1+i}$ for $t < 0$; so $f'(0)$ does not exist. Existence of the partial derivatives only concerns the two directions of the axes, while complex differentiability concerns all directions at once.

Corollary 29.4.7. *1. (Liouville) A bounded entire function is constant; more generally, if* $|f(z)| \leq C(1+|z|)^m$ *for an entire* f*, then* f *is a polynomial of degree at most* m*.*

2. (Fundamental theorem of algebra) Every nonconstant polynomial over $\mathbb{C}$ *has a root (cf. Chapter 9).*

3. (Morera) A continuous function on an open set whose integral over the boundary of every closed triangle contained in the set vanishes is holomorphic.

4. (Weierstrass) If holomorphic functions f_n *on* U *converge uniformly on compact subsets to* f*, then* f *is holomorphic and* $f_n^{(k)} \to f^{(k)}$ *uniformly on compact subsets.*

Proof. (1) By the Cauchy estimates with $r \to \infty$, $f^{(n)}(a) = 0$ for $n > m$ and all a. (2) If p has no root, $1/p$ is entire and tends to 0 at infinity, hence is bounded and constant. (3) Locally on a disc the hypothesis gives a primitive F as in Corollary 29.3.2, and F is holomorphic, hence so is $F' = f$ by Theorem 29.4.2. (4) The uniform limit is continuous and satisfies Morera's condition by Theorem 29.3.1 and uniform convergence; convergence of derivatives follows from the Cauchy integral formula for $f^{(k)}$ on circles inside U. □

Remark 29.4.8. *Is f holomorphic if and only if $\partial f/\partial\bar z = 0$?* Yes, with two provisos: the equation must hold on an open set, and f must be real differentiable there (for instance of class C^1), since the Wirtinger derivatives are only defined for such functions.

1. *Open sets.* Holomorphy is a condition on an open set, and $\partial f/\partial\bar z = 0$ at a single point only gives complex differentiability at that point. For $f(z) = |z|^2 = z\bar z$, $\partial f/\partial\bar z = z$ vanishes only at 0: f is complex differentiable at 0, with $f'(0) = \lim \bar h = 0$, and nowhere else, so it is holomorphic on no open set.

2. *Real differentiability.* Requiring only that the partial derivatives exist and satisfy the Cauchy–Riemann equations is not enough, even at every point of an open set. Let $f(z) = e^{-z^{-4}}$ for $z \neq 0$ and $f(0) = 0$. Away from 0, f is holomorphic. On the real axis $f(x) = e^{-x^{-4}}$, and on the imaginary axis $f(iy) = e^{-y^{-4}}$ since $(iy)^4 = y^4$; both tend to 0 faster than any power, so $\partial_x f(0) = \partial_y f(0) = 0$ and the Cauchy–Riemann equations hold everywhere. But on the diagonal $z = re^{i\pi/4}$, $z^4 = -r^4$ and $f(z) = e^{r^{-4}} \to \infty$ as $r \to 0$: f is not even continuous at 0. Counterexample 29.4.6 shows the same phenomenon at a single point for a continuous function.

3. *The Looman–Menchoff theorem.* Continuity is the only thing missing in (2): if f is continuous on U, its partial derivatives exist at every point of U and satisfy the Cauchy–Riemann equations, then f is holomorphic [GM78]. The proof is delicate (it uses Baire's theorem); we do not need it.

4. *Weak solutions.* The equation can also be imposed in the weak sense, by moving the derivative onto test functions; then continuity alone suffices, as the next proposition shows. This is the point of view of distributions (Chapter 32), in which every locally integrable weak solution of $\partial f/\partial\bar z = 0$ agrees almost everywhere with a holomorphic function, a first case of elliptic regularity (Remark 29.4.4).

Proposition 29.4.9. *Let $U \subseteq \mathbb{C}$ be open and $f : U \to \mathbb{C}$ continuous. Then f is holomorphic if and only if*

$$\int_U f\,\frac{\partial\varphi}{\partial\bar z}\,dA = 0 \qquad \text{for every smooth } \varphi : U \to \mathbb{C} \text{ with compact support,}$$

where $dA = dx\,dy$ is Lebesgue measure.

Proof. Necessity. If f is holomorphic, it is C^∞ (Corollary 29.4.3). Extend $f\varphi$ by 0 outside the support of φ; it is then a C^1 function on $\mathbb{C}$ with compact support. For fixed y, $\int_{\mathbb{R}} \partial_x(f\varphi)\,dx = 0$ by the fundamental theorem of calculus, and likewise for ∂_y; integrating over the other variable (Fubini's theorem), $\int (f\,\partial_x\varphi + \varphi\,\partial_x f)\,dA = 0$, and similarly for y. Combining, $\int f\,\partial\varphi/\partial\bar z\,dA = -\int \varphi\,\partial f/\partial\bar z\,dA = 0$.

Sufficiency. By Corollary 27.10.8 there is a smooth $\rho \geq 0$ on $\mathbb{C}$ with support in the unit disc and $\int \rho\,dA = 1$; put $\rho_\varepsilon(w) = \varepsilon^{-2}\rho(w/\varepsilon)$, which has support in $\overline{D}(0,\varepsilon)$ and integral 1. Let $U_\varepsilon = \{z : \overline{D}(z,\varepsilon) \subseteq U\}$, an open set, and for $z \in U_\varepsilon$

$$f_\varepsilon(z) = \int_U f(w)\,\rho_\varepsilon(z-w)\,dA(w).$$

Step 1: f_ε is C^1 on U_ε, with derivatives obtained by differentiating ρ_ε. Fix $z_0 \in U_\varepsilon$ and $\delta > 0$ with $\overline{D}(z_0, \varepsilon+\delta) \subseteq U$. For $|z - z_0| < \delta$ the integrand vanishes outside the compact disc $K = \overline{D}(z_0, \varepsilon+\delta)$, and $|f(w)\,\partial_x\rho_\varepsilon(z-w)| \leq \sup_K|f| \cdot \sup|\partial_x\rho_\varepsilon| \cdot 1_K(w)$, an integrable bound independent of z. By Proposition 28.4.13, applied to the real and imaginary parts,

$\partial_x f_\varepsilon(z) = \int f(w)(\partial_x \rho_\varepsilon)(z-w)\,dA(w)$, and similarly for ∂_y. These are continuous in z, by dominated convergence with the same bound, so f_ε is C^1, and

$$\frac{\partial f_\varepsilon}{\partial \bar z}(z) = \int_U f(w)\,\frac{\partial \rho_\varepsilon}{\partial \bar z}(z-w)\,dA(w).$$

Step 2: f_ε is holomorphic. For fixed $z \in U_\varepsilon$ the function $\varphi(w) = \rho_\varepsilon(z-w)$ is smooth with compact support in U, and by the chain rule $\partial_x\varphi(w) = -(\partial_x\rho_\varepsilon)(z-w)$ and $\partial_y\varphi(w) = -(\partial_y\rho_\varepsilon)(z-w)$, so $\partial\varphi/\partial\bar w = -(\partial\rho_\varepsilon/\partial\bar z)(z-w)$. The hypothesis gives $\partial f_\varepsilon/\partial\bar z(z) = -\int f\,\partial\varphi/\partial\bar w\,dA = 0$. So f_ε is real differentiable with $\partial f_\varepsilon/\partial\bar z = 0$ on U_ε, hence holomorphic there.

Step 3: $f_\varepsilon \to f$ uniformly on compact sets. Let $C \subseteq U$ be compact and $\varepsilon_0 > 0$ with $C' = \{w : \operatorname{dist}(w, C) \le \varepsilon_0\} \subseteq U$; then $C \subseteq U_\varepsilon$ for $\varepsilon \le \varepsilon_0$. Substituting $w \mapsto z - w$ and using $\int \rho_\varepsilon = 1$, for $z \in C$

$$|f_\varepsilon(z) - f(z)| = \left|\int \big(f(z-w) - f(z)\big)\rho_\varepsilon(w)\,dA(w)\right| \le \sup\{|f(z-w) - f(z)| : |w| \le \varepsilon\},$$

which tends to 0 uniformly in $z \in C$, because f is uniformly continuous on the compact set C'. Every compact subset of U lies in U_ε for small ε, so by Weierstrass's theorem (Corollary 29.4.7(4)), applied on the open sets U_{ε_0}, f is holomorphic on each U_{ε_0}, hence on U. □

The function f_ε is a *regularisation* of f by convolution with the *mollifier* ρ_ε: it is smooth, close to f, and it inherits every linear constant-coefficient equation that f satisfies weakly. The weak equation must hold on all of U: $1/z$ is holomorphic on $\mathbb{C}^\times$ and locally integrable on $\mathbb{C}$, but on $\mathbb{C}$ it does not satisfy the weak equation, since $\int (1/z)\,\partial\varphi/\partial\bar z\,dA = -\pi\varphi(0)$ (Exercise 29.8.15); the point 0 carries a "source".

Theorem 29.4.10 (Identity theorem)**.** *Let f be holomorphic on a domain U. If the zero set of f has a limit point in U, then $f \equiv 0$. Consequently two holomorphic functions agreeing on a set with a limit point in U are equal, and the zeros of a nonzero f are isolated, each of finite order m with $f(z) = (z-a)^m g(z)$, g holomorphic and $g(a) \neq 0$.*

Proof. Let A be the set of $a \in U$ with $f^{(n)}(a) = 0$ for all n; it is closed in U, and open because f vanishes identically near such a point by Theorem 29.4.2. If $z_k \to a$ with $z_k \neq a$ and $f(z_k) = 0$, and if some derivative at a were nonzero, then with m minimal, $f(z) = (z-a)^m g(z)$ with $g(a) \neq 0$ by the power series expansion, so f would have no zeros near a other than a. Hence $a \in A$, and $A = U$ by connectedness. □

Theorem 29.4.11 (Maximum modulus principle)**.** *Let f be holomorphic on a domain U. If $|f|$ has a local maximum in U, then f is constant. If moreover U is bounded and f extends continuously to $\overline{U}$, then $|f|$ attains its maximum on ∂U.*

Proof. Theorem 29.4.1 on circles gives the mean value property $f(a) = \int_0^1 f(a + re^{2\pi it})\,dt$. If $|f| \le |f(a)|$ on $D(a,R)$, then for $r < R$, $|f(a)| \le \int_0^1 |f(a + re^{2\pi it})|\,dt \le |f(a)|$, so $|f| = |f(a)|$ on every such circle by continuity, and $|f|$ is constant on $D(a,R)$. Then $f\bar f$ is constant; if $f(a) \neq 0$ this makes $\bar f = c/f$ holomorphic, so both f and $\bar f$ satisfy the Cauchy–Riemann equations and $f' = 0$ on the disc. In either case f is constant on $D(a,R)$, hence on U by Theorem 29.4.10. The last statement follows from compactness of $\overline{U}$. □

29.5 Singularities, Laurent series and residues

Theorem 29.5.1 (Laurent expansion)**.** *Let f be holomorphic on the annulus $A = \{r < |z-a| < R\}$, $0 \le r < R \le \infty$. There are unique $c_n \in \mathbb{C}$, $n \in \mathbb{Z}$, with $f(z) = \sum_{n\in\mathbb{Z}} c_n (z-a)^n$, converging absolutely and uniformly on compact subsets of A, and $c_n = \frac{1}{2\pi i}\int_{\partial D(a,\rho)} \frac{f(z)}{(z-a)^{n+1}}dz$ for any $r < \rho < R$.*

Proof. Fix w with $r < r_1 < |w-a| < r_2 < R$. The function $g(z) = (f(z) - f(w))/(z-w)$, extended by $f'(w)$ at w, is continuous on A and holomorphic off w, hence holomorphic by Corollary 29.4.7(3) and Theorem 29.3.1. The circles $\partial D(a, r_1)$ and $\partial D(a, r_2)$ are homotopic as closed paths in A (move radially), so $\int_{\partial D(a,r_2)} g = \int_{\partial D(a,r_1)} g$ by Theorem 29.3.3. Since $n(\partial D(a, r_2), w) = 1$ and $n(\partial D(a, r_1), w) = 0$, this gives

$$f(w) = \frac{1}{2\pi i}\int_{\partial D(a,r_2)} \frac{f(z)}{z-w}dz - \frac{1}{2\pi i}\int_{\partial D(a,r_1)} \frac{f(z)}{z-w}dz.$$

In the first integral expand $\frac{1}{z-w} = \sum_{n\ge 0} \frac{(w-a)^n}{(z-a)^{n+1}}$, in the second $\frac{-1}{z-w} = \sum_{n\ge 1} \frac{(z-a)^{n-1}}{(w-a)^n}$, both uniformly convergent on the respective circles, and integrate term by term. The resulting coefficients are independent of the radius, again by homotopy invariance. Uniqueness follows by integrating the series against $(z-a)^{-n-1}$ term by term. □

Definition 29.5.2. Let f be holomorphic on a punctured disc $D(a, R) \setminus \{a\}$, with Laurent coefficients c_n. The singularity at a is *removable* if $c_n = 0$ for all $n < 0$, a *pole of order m* if $c_{-m} \ne 0$ and $c_n = 0$ for $n < -m$, and *essential* otherwise. The *residue* is $\operatorname{Res}_a f = c_{-1}$. A function holomorphic on U except for poles at a discrete closed subset is *meromorphic*; the *order* $\operatorname{ord}_a f$ is m at a zero of order m and $-m$ at a pole of order m.

Proposition 29.5.3. *Let f be holomorphic on $D(a, R) \setminus \{a\}$.*

1. *(Riemann) If f is bounded near a, the singularity is removable.*
2. *The singularity is a pole if and only if $|f(z)| \to \infty$ as $z \to a$.*
3. *(Casorati–Weierstrass) If the singularity is essential, $f(D(a, \varepsilon) \setminus \{a\})$ is dense in $\mathbb{C}$ for every $\varepsilon > 0$.*

Proof. (1) If $|f| \le M$ near a, then $|c_{-n}| \le M\rho^n$ for small ρ by Theorem 29.5.1, so $c_{-n} = 0$ for $n \ge 1$. (2) If f has a pole of order m, then $(z-a)^m f(z)$ extends holomorphically with nonzero value at a, so $|f| \to \infty$. Conversely, if $|f| \to \infty$, then $1/f$ is holomorphic and nonvanishing near a with limit 0, so by (1) it extends with a zero of some order m at a, and $f = 1/(1/f)$ has a pole of order m. (3) If the image of some punctured disc misses $D(w, \delta)$, then $g = 1/(f-w)$ is bounded there, hence extends holomorphically by (1); then $f = w + 1/g$ has a removable singularity or a pole by (2). □

Example 29.5.4. The function $f(z) = e^{1/z}$ on $\mathbb{C} \setminus \{0\}$ has Laurent series $\sum_{n\ge 0} z^{-n}/n!$, so 0 is an essential singularity. More than Casorati–Weierstrass holds here: every $w \ne 0$ is taken infinitely often in every punctured disc around 0. Indeed, if $w = e^c$, the points $z_k = 1/(c + 2\pi i k)$, $k \in \mathbb{Z}$, satisfy $f(z_k) = w$ and tend to 0. The value 0 is never taken. On the real axis, $e^{1/x} \to \infty$ as $x \to 0^+$ and $\to 0$ as $x \to 0^-$, while along the imaginary axis $|e^{1/(iy)}| = 1$: the behaviour near an essential singularity depends on the direction of approach.

Counterexample 29.5.5. Real analysis does not see the radius of convergence. The function $g(x) = 1/(1+x^2)$ is real-analytic on all of $\mathbb{R}$, but its Taylor series $\sum_n (-1)^n x^{2n}$ at 0 has radius of convergence 1. The reason is complex: g extends to the meromorphic function $1/(1+z^2)$

with poles at $\pm i$, at distance 1 from 0. By Theorem 29.4.2 the series converges on $D(0,1)$, and it cannot converge on a larger disc: its sum would be holomorphic there, equal to $1/(1+z^2)$ on $D(0,1)$ by the identity theorem, hence bounded near i, whereas $|1/(1+z^2)| \to \infty$ as $z \to i$. Similarly $x \mapsto e^{-1/x^2}$ (extended by 0) is smooth on $\mathbb{R}$ with all derivatives zero at 0, so it is not real-analytic there; as a complex function, e^{-1/z^2} has an essential singularity at 0, and it is unbounded along the imaginary axis.

Lemma 29.5.6. *Let h be holomorphic on an open U and define $g\colon U \times U \to \mathbb{C}$ by $g(z,w) = (h(z)-h(w))/(z-w)$ for $z \neq w$ and $g(z,z) = h'(z)$. Then g is continuous, and holomorphic in each variable separately.*

Proof. Holomorphy in each variable off the diagonal is clear, and at $z = w$ the singularity is removable by Proposition 29.5.3(1), since g is bounded near it by the estimate below. For continuity at (a,a), take $\overline{D}(a,r) \subseteq U$; for $z, w \in D(a,r)$ the segment $[w,z]$ lies in the disc and $g(z,w) = \int_0^1 h'(w + t(z-w))\,dt$ (by the fundamental theorem of calculus applied to $t \mapsto h(w+t(z-w))$, also valid when $z = w$). Since h' is continuous, hence uniformly continuous on $\overline{D}(a, r/2)$, this expression is continuous in (z,w) there. □

Theorem 29.5.7 (Cauchy's theorem, homology form)**.** *Let h be holomorphic on an open $U \subseteq \mathbb{C}$ and let γ be a closed path in U with $n(\gamma, z) = 0$ for every $z \in \mathbb{C} \setminus U$. Then $\int_\gamma h = 0$, and $n(\gamma,w)h(w) = \frac{1}{2\pi i}\int_\gamma \frac{h(z)}{z-w}\,dz$ for every $w \in U \setminus \gamma^*$.*

Proof. (Dixon.) With g as in Lemma 29.5.6, let $\varphi(w) = \frac{1}{2\pi i}\int_\gamma g(z,w)\,dz$ for $w \in U$. It is continuous, since g is uniformly continuous on $\gamma^* \times K$ for compact $K \subseteq U$, and holomorphic: for a closed triangle $T \subseteq U$, Fubini's theorem for continuous functions (Proposition 27.8.9) and Theorem 29.3.1 give $\int_{\partial T} \varphi(w)\,dw = \frac{1}{2\pi i}\int_\gamma \left(\int_{\partial T} g(z,w)\,dw\right) dz = 0$, so Morera's theorem applies. Let $V = \{w \in \mathbb{C} \setminus \gamma^* : n(\gamma,w) = 0\}$, an open set, and $\psi(w) = \frac{1}{2\pi i}\int_\gamma \frac{h(z)}{z-w}\,dz$ on V, which is holomorphic (same argument). For $w \in U \cap V$, $\varphi(w) = \psi(w) - n(\gamma,w)h(w) = \psi(w)$. By hypothesis $U \cup V = \mathbb{C}$, so φ and ψ define an entire function F. The unbounded component of $\mathbb{C} \setminus \gamma^*$ lies in V, and $\psi(w) \to 0$ as $|w| \to \infty$; so F is bounded, hence constant equal to 0 by Liouville's theorem (Corollary 29.4.7). Thus $\varphi \equiv 0$, which is the integral formula. Applying it to $z \mapsto (z-w)h(z)$ at the point w gives $0 = \frac{1}{2\pi i}\int_\gamma h$. □

Theorem 29.5.8 (Residue theorem)**.** *Let U be simply connected and open, $S \subseteq U$ discrete and closed in U, and f holomorphic on $U \setminus S$. For every closed path γ in $U \setminus S$,*

$$\frac{1}{2\pi i}\int_\gamma f = \sum_{a \in S} n(\gamma, a)\operatorname{Res}_a f,$$

a finite sum.

Proof. Let $W = \{z \in \mathbb{C} \setminus \gamma^* : n(\gamma,z) \neq 0\}$, a union of bounded components of $\mathbb{C} \setminus \gamma^*$, so $K = \overline{W} \subseteq W \cup \gamma^*$ is compact. If $z \notin U$, then $1/(w-z)$ is holomorphic on the simply connected U, hence has a primitive, so $n(\gamma,z) = 0$; therefore $K \subseteq U$, and $S \cap K$ is finite, say $\{a_1, \dots, a_k\}$, because S is discrete and closed in U. Let $P_j(z) = \sum_{n \geq 1} c_{-n}^{(j)}(z-a_j)^{-n}$ be the principal part of f at a_j. It converges locally uniformly on $\mathbb{C} \setminus \{a_j\}$, because the Laurent series of f converges on the punctured disc and the principal part, as a power series in $1/(z-a_j)$, then has infinite radius of convergence; so P_j is holomorphic there. The function $h = f - \sum_j P_j$ has removable singularities at $a_1, \dots, a_k$, hence extends holomorphically to $U' = U \setminus (S \setminus \{a_1, \dots, a_k\})$. For $z \notin U'$ we have $n(\gamma,z) = 0$: either $z \notin U$, or $z \in S \setminus \{a_1, \dots, a_k\}$, which was excluded from

K. So $\int_\gamma h = 0$ by Theorem 29.5.7. Finally $\int_\gamma P_j = 2\pi i\, n(\gamma, a_j) c_{-1}^{(j)}$, since the terms with $n \geq 2$ have primitives, and $n(\gamma, a) = 0$ for the remaining $a \in S$. □

Example 29.5.9. $\int_{-\infty}^{\infty} \frac{dx}{1+x^2} = \pi$. Integrate $f(z) = 1/(1+z^2)$ over the boundary of the half-disc $\{|z| \leq R, \operatorname{Im} z \geq 0\}$: the only singularity inside is the simple pole at i with residue $\lim_{z\to i}(z-i)f(z) = 1/(2i)$, so the integral is π. The contribution of the semicircle is at most $\pi R/(R^2-1) \to 0$, and the integral over $[-R, R]$ tends to the improper integral.

Theorem 29.5.10 (Argument principle and Rouché)**.** *Let U be simply connected, f meromorphic on U and γ a closed path in U avoiding the zeros and poles of f. Then $\frac{1}{2\pi i}\int_\gamma \frac{f'}{f} = \sum_a n(\gamma, a) \operatorname{ord}_a f$. If g is holomorphic on U and $|f-g| < |f|$ on γ^*, with f holomorphic, then f and g have the same number of zeros counted with multiplicity and weighted by $n(\gamma, -)$.*

Proof. Near a zero or pole, $f(z) = (z-a)^m h(z)$ with $h(a) \neq 0$ and $m = \operatorname{ord}_a f$, so $f'/f = m/(z-a) + h'/h$ has residue m at a; apply Theorem 29.5.8. For Rouché's theorem, the functions $f_t = f + t(g-f)$, $t \in [0,1]$, have no zeros on γ^* because $|f_t| \geq |f| - |g-f| > 0$; the integer $N(t) = \frac{1}{2\pi i}\int_\gamma f_t'/f_t$ depends continuously on t (the integrand is continuous in (t,z) and γ^* is compact), hence is constant. □

Example 29.5.11. *More proofs of the fundamental theorem of algebra.* Let $p(z) = z^n + a_{n-1}z^{n-1} + \cdots + a_0$, $n \geq 1$. Besides the algebraic proof (Theorem 9.7.3, by Galois theory and the intermediate value theorem) and Liouville's theorem (Corollary 29.4.7(2)):

1. *By Rouché's theorem, or by winding numbers.* On the circle $|z| = R$ with $R > 1 + \sum_i |a_i|$, $|p(z) - z^n| \leq \sum_i |a_i| R^i < R^n = |z^n|$. By the theorem, p has as many zeros in $|z| < R$ as z^n, namely n, counted with multiplicity. Topologically: the loops $t \mapsto p(Re^{it})$ and $t \mapsto R^n e^{int}$ in $\mathbb{C} \setminus 0$ are homotopic, so they have the same winding number n about 0; if p had no zeros, $t \mapsto p(re^{it})$, $0 \leq r \leq R$, would be a homotopy in $\mathbb{C} \setminus 0$ to a constant loop, of winding number 0.

2. *By the minimum modulus (d'Alembert–Argand).* Since $|p(z)| \geq |z|^n(1 - \sum_i |a_i||z|^{i-n}) \to \infty$, $|p|$ attains a minimum on $\mathbb{C}$ (on a large closed disc by compactness, and outside it $|p| > |p(0)|$). Suppose the minimum is attained at z_0 with $p(z_0) \neq 0$. Expanding in h, $p(z_0+h) = p(z_0) + ch^k + h^{k+1}q(h)$ with $c \neq 0$, $k \geq 1$ and q a polynomial. Choose ζ with $c\zeta^k = -p(z_0)$ (k-th roots exist by the polar form). For $0 < t < 1$, $p(z_0 + t\zeta) = (1-t^k)p(z_0) + t^{k+1}\zeta^{k+1}q(t\zeta)$, so $|p(z_0+t\zeta)| \leq (1-t^k)|p(z_0)| + Ct^{k+1} < |p(z_0)|$ for small $t > 0$, contradicting minimality. This proof uses only that $\mathbb{C}$ has k-th roots and that continuous functions on compact sets have minima.

Theorem 29.5.12 (Open mapping theorem)**.** *A nonconstant holomorphic function on a domain is an open map. If it is injective, its derivative has no zeros and its inverse is holomorphic.*

Proof. Let $w_0 = f(z_0)$. By Theorem 29.4.10 the zero of $f - w_0$ at z_0 has finite order $m \geq 1$ and is isolated, so there is r with $|f - w_0| \geq \delta > 0$ on $|z - z_0| = r$ and no other zero in $\overline{D}(z_0, r)$. For $|w - w_0| < \delta$, Rouché's theorem applied to $f - w_0$ and $f - w$ on the circle shows that $f - w$ has m zeros in $D(z_0, r)$; so $D(w_0, \delta) \subseteq f(D(z_0, r))$. If f is injective, then $m = 1$ at every point, that is, $f' \neq 0$; and f^{-1} is continuous because f is open, and differentiable with derivative $1/f'(f^{-1})$ by the computation of Proposition 27.6.8, valid over $\mathbb{C}$. □

29.6 Conformal maps and the Riemann mapping theorem

Lemma 29.6.1 (Schwarz)**.** *Let $f : \mathbb{D} \to \mathbb{D}$ be holomorphic with $f(0) = 0$. Then $|f(z)| \leq |z|$ and $|f'(0)| \leq 1$, with equality for some $z \neq 0$ or in the second inequality only if $f(z) = \lambda z$ with $|\lambda| = 1$.*

Proof. The function $g(z) = f(z)/z$, extended by $f'(0)$ at 0, is holomorphic on $\mathbb{D}$ (Proposition 29.5.3(1)). On $|z| = r$, $|g| \le 1/r$, so by the maximum principle $|g| \le 1/r$ on $D(0, r)$; letting $r \to 1$ gives $|g| \le 1$. Equality at an interior point forces g to be a constant of modulus 1. □

Proposition 29.6.2. *For $a \in \mathbb{D}$ the Möbius map $\phi_a(z) = \frac{z-a}{1-\bar{a}z}$ is a biholomorphic self-map of $\mathbb{D}$ with $\phi_a(a) = 0$ and inverse ϕ_{-a}. Every biholomorphic self-map of $\mathbb{D}$ is $z \mapsto \lambda\phi_a(z)$ with $|\lambda| = 1$.*

Proof. For $|z| < 1$ and $|a| < 1$, $|1 - \bar{a}z|^2 - |z - a|^2 = (1 - |a|^2)(1 - |z|^2) > 0$, so ϕ_a maps $\mathbb{D}$ into $\mathbb{D}$, and a computation gives $\phi_{-a}\phi_a = \mathrm{id}$. If F is a biholomorphic self-map with $F(a) = 0$, then $g = F \circ \phi_{-a}$ fixes 0, and Lemma 29.6.1 applied to g and g^{-1} gives $|g'(0)| = 1$, hence $g(z) = \lambda z$. □

Theorem 29.6.3 (Montel)**.** *Let $\mathcal{F}$ be a family of holomorphic functions on an open U that is uniformly bounded on every compact subset. Then every sequence in $\mathcal{F}$ has a subsequence converging uniformly on compact subsets to a holomorphic function.*

Proof. Let $K \subseteq U$ be compact and 2ρ the distance from K to $\mathbb{C} \setminus U$ (or 1 if $U = \mathbb{C}$), and let K' be the set of points at distance $\le \rho$ from K, a compact subset of U. By the Cauchy estimates, $|f'| \le \rho^{-1} \sup_{K'} |f|$ on K for all $f \in \mathcal{F}$, so $\mathcal{F}$ is equicontinuous on K (mean value inequality). By the Arzelà–Ascoli theorem (Theorem 27.15.4) a sequence has a subsequence converging uniformly on K. Exhausting U by compact sets $K_1 \subseteq K_2 \subseteq \cdots$ and taking a diagonal subsequence gives uniform convergence on all compact subsets; the limit is holomorphic by Corollary 29.4.7(4). □

Theorem 29.6.4 (Hurwitz)**.** *Let $f_n \to f$ uniformly on compact subsets of a domain U, with f_n holomorphic and f nonconstant. If every f_n is nowhere zero, so is f; if every f_n is injective, so is f.*

Proof. Suppose $f(z_0) = 0$. Since $f \not\equiv 0$, there is r with $\overline{D}(z_0, r) \subseteq U$ and $f \neq 0$ on the circle $|z - z_0| = r$, so $|f| \ge \delta > 0$ there. Then $f_n \to f$ and $f_n' \to f'$ uniformly on the circle, so $\frac{1}{2\pi i}\int f_n'/f_n \to \frac{1}{2\pi i}\int f'/f \ge 1$, and by Theorem 29.5.10 f_n has a zero inside for large n. For injectivity, if $f(z_1) = f(z_2)$ with $z_1 \neq z_2$, apply the first part on a punctured neighbourhood of z_2 to the functions $f_n - f_n(z_1)$, which are nowhere zero there. □

Theorem 29.6.5 (Riemann mapping theorem)**.** *Every simply connected domain $U \subsetneq \mathbb{C}$ is biholomorphic to $\mathbb{D}$. More precisely, for $z_0 \in U$ there is a unique biholomorphic $\psi\colon U \to \mathbb{D}$ with $\psi(z_0) = 0$ and $\psi'(z_0) > 0$.*

Proof. Let $\mathcal{F}$ be the set of injective holomorphic maps $U \to \mathbb{D}$ sending z_0 to 0.

$\mathcal{F} \neq \emptyset$. Choose $b \notin U$. Since $z - b$ is nowhere zero on the simply connected U, the function $(z - b)'/(z - b)$ has a primitive h (Theorem 29.3.3); adjusting by a constant, $e^h = z - b$. Let $\phi = e^{h/2}$, so $\phi^2 = z - b$. Then ϕ is injective, and $\phi(z_1) = -\phi(z_2)$ implies $z_1 = z_2$ and $\phi(z_1) = 0$, which is impossible; so $\phi(U)$ and $-\phi(U)$ are disjoint. By Theorem 29.5.12, $\phi(U)$ contains a disc $D(w_0, \varrho)$, hence $|\phi(z) + w_0| \ge \varrho$ on U, and $z \mapsto \varrho/(\phi(z) + w_0)$ maps U injectively into $\mathbb{D}$. Composing with a suitable ϕ_a (Proposition 29.6.2) gives an element of $\mathcal{F}$.

An extremal element. Injective holomorphic maps have nonvanishing derivative, so $\eta = \sup_{\psi \in \mathcal{F}} |\psi'(z_0)| > 0$. Take $\psi_n \in \mathcal{F}$ with $|\psi_n'(z_0)| \to \eta$; by Theorem 29.6.3 a subsequence converges uniformly on compact subsets to a holomorphic ψ with $|\psi'(z_0)| = \eta > 0$, so ψ is nonconstant, hence injective by Theorem 29.6.4, with $\psi(z_0) = 0$ and $|\psi| \le 1$; by the open mapping theorem $\psi(U) \subseteq \mathbb{D}$. So $\psi \in \mathcal{F}$ and $|\psi'(z_0)| = \eta$.

Surjectivity. Suppose $\alpha \in \mathbb{D} \setminus \psi(U)$. Then $\phi_\alpha \circ \psi$ is nowhere zero on U, so as above it has a holomorphic square root g, which is injective because g^2 is. Let $F = \phi_{g(z_0)} \circ g \in \mathcal{F}$. Writing $s(w) = w^2$, we have $\psi = \phi_{-\alpha} \circ s \circ \phi_{-g(z_0)} \circ F = \Phi \circ F$ with $\Phi\colon \mathbb{D} \to \mathbb{D}$ holomorphic and $\Phi(0) = 0$. As s is not injective, Φ is not injective, so Φ is not a rotation and $|\Phi'(0)| < 1$

by Lemma 29.6.1. Then $\eta = |\psi'(z_0)| = |\Phi'(0)|\,|F'(z_0)| < |F'(z_0)| \le \eta$, a contradiction. So ψ is a biholomorphism onto $\mathbb{D}$, and multiplying by a unimodular constant makes $\psi'(z_0) > 0$.

Uniqueness. If ψ_1, ψ_2 both work, $\psi_2 \circ \psi_1^{-1}$ is an automorphism of $\mathbb{D}$ fixing 0 with positive derivative there, hence the identity by Proposition 29.6.2. □

Remark 29.6.6. A real function u on an open $U \subseteq \mathbb{C}$ is *harmonic* if it is C^2 with $\partial_x^2 u + \partial_y^2 u = 0$. Real and imaginary parts of holomorphic functions are harmonic (Corollary 29.4.3). Conversely, on a simply connected U every harmonic u is the real part of a holomorphic function: the function $\partial_x u - i\partial_y u$ is holomorphic (its Cauchy–Riemann equations are the harmonicity of u and the symmetry of second derivatives), so it has a primitive f, and $\operatorname{Re} f$ differs from u by a constant. Harmonic functions therefore satisfy the mean value property and the maximum principle; this is the one-variable case of the Hodge theory of Chapter 43.

29.7 The Riemann sphere

Many statements of complex analysis become simpler once the point ∞ is added to the plane: a pole is a point where a function takes the value ∞, lines are circles through ∞, and the rational functions are exactly the functions that are meromorphic everywhere, ∞ included. The resulting space is a sphere, the first example of a compact Riemann surface; its symmetries, the Möbius transformations, form the group $\mathrm{PSL}_2(\mathbb{C})$, which reappears in hyperbolic geometry, in the theory of modular forms and in the classification of Riemann surfaces.

29.7.1 The sphere and stereographic projection

Definition 29.7.1. The *Riemann sphere* is the one-point compactification $\hat{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$ of $\mathbb{C}$ (Definition 18.9.2). The neighbourhoods of ∞ are the sets containing $\{|z| > R\} \cup \{\infty\}$ for some R, so $z_n \to \infty$ in $\hat{\mathbb{C}}$ if and only if $|z_n| \to \infty$.

Identifying $\mathbb{C}$ with $\mathbb{R}^2$ by $z = x + iy \mapsto (x, y)$, Example 18.9.4 gives a homeomorphism $\tau\colon \hat{\mathbb{C}} \to S^2 \subseteq \mathbb{R}^3$,

$$\tau(z) = \frac{(2x, 2y, |z|^2 - 1)}{|z|^2 + 1} = \frac{(2\operatorname{Re} z, 2\operatorname{Im} z, |z|^2 - 1)}{|z|^2 + 1}, \qquad \tau(\infty) = N = (0, 0, 1),$$

whose inverse is the stereographic projection from the north pole N: the point $\tau(z)$ is the second intersection of S^2 with the line through N and $(x, y, 0)$. The unit circle is mapped to the equator, the unit disc $\mathbb{D}$ to the southern hemisphere, 0 to the south pole and ∞ to the north pole.

Proposition 29.7.2. *1. (*Chordal distance*) For $z, w \in \mathbb{C}$,*

$$\|\tau(z) - \tau(w)\| = \frac{2|z - w|}{\sqrt{(1 + |z|^2)(1 + |w|^2)}}, \qquad \|\tau(z) - N\| = \frac{2}{\sqrt{1 + |z|^2}}.$$

2. The map $z \mapsto 1/z$, with $0 \mapsto \infty \mapsto 0$, corresponds to the rotation by the angle π about the x_1-axis: $\tau(1/z) = (x_1, -x_2, -x_3)$ if $\tau(z) = (x_1, x_2, x_3)$. In particular it preserves the chordal distance.

Proof. (1) Since $\|\tau(z)\| = \|\tau(w)\| = 1$, $\|\tau(z) - \tau(w)\|^2 = 2 - 2\langle\tau(z), \tau(w)\rangle$, and

$$2 - 2\langle\tau(z), \tau(w)\rangle = 2\,\frac{(|z|^2 + 1)(|w|^2 + 1) - 4\operatorname{Re}(z\bar{w}) - (|z|^2 - 1)(|w|^2 - 1)}{(|z|^2 + 1)(|w|^2 + 1)} = \frac{4(|z|^2 + |w|^2 - 2\operatorname{Re}(z\bar{w}))}{(|z|^2 + 1)(|w|^2 + 1)},$$

which is $4|z-w|^2/((1+|z|^2)(1+|w|^2))$. The second formula is in Example 18.9.4.

(2) For $z \neq 0$, $1/z = \bar{z}/|z|^2$ has real part $x/|z|^2$ and imaginary part $-y/|z|^2$, so

$$\tau(1/z) = \frac{(2x/|z|^2, -2y/|z|^2, 1/|z|^2 - 1)}{1/|z|^2 + 1} = \frac{(2x, -2y, 1-|z|^2)}{1+|z|^2},$$

which is $(x_1, -x_2, -x_3)$; and τ maps 0 and ∞ to the south and north poles, which the rotation exchanges. □

A *generalised circle* in $\hat{\mathbb{C}}$ is either a circle in $\mathbb{C}$ or a set $L \cup \{\infty\}$ with L a line in $\mathbb{C}$. Every generalised circle is the set of solutions in $\hat{\mathbb{C}}$ of an equation

$$A|z|^2 + 2\beta x + 2\gamma y + C = 0, \qquad A, \beta, \gamma, C \in \mathbb{R}, \quad \beta^2 + \gamma^2 > AC, \tag{29.1}$$

where ∞ counts as a solution when $A = 0$: for $A \neq 0$ this is the circle with centre $-(\beta + i\gamma)/A$ and radius $\sqrt{\beta^2+\gamma^2-AC}/|A|$, and for $A = 0$ a line. Through any three distinct points of $\hat{\mathbb{C}}$ passes exactly one generalised circle: the circle through three non-collinear points of $\mathbb{C}$, the line through three collinear ones, and the line through the two finite points if one of them is ∞.

Proposition 29.7.3. *The map τ induces a bijection between the generalised circles in $\hat{\mathbb{C}}$ and the circles on S^2, that is, the intersections of S^2 with planes at distance less than 1 from the origin. The lines correspond to the circles through N.*

Proof. A plane is $\{ax_1 + bx_2 + cx_3 = d\}$ with $a^2+b^2+c^2 = 1$, and it meets S^2 in a circle exactly when $|d| < 1$. The point $\tau(z)$, $z \in \mathbb{C}$, lies on it if and only if $2ax + 2by + c(|z|^2 - 1) = d(|z|^2 + 1)$, that is,

$$(c-d)|z|^2 + 2ax + 2by - (c+d) = 0,$$

an equation of the form (29.1) with $A = c-d$, $\beta = a$, $\gamma = b$, $C = -(c+d)$, for which $\beta^2+\gamma^2-AC = a^2+b^2+c^2-d^2 = 1-d^2 > 0$. The point $N = \tau(\infty)$ lies on the plane if and only if $c = d$, that is, $A = 0$. Conversely, given (A, β, γ, C) with $\beta^2+\gamma^2 > AC$, the numbers $a = s\beta$, $b = s\gamma$, $c = s(A-C)/2$, $d = -s(A+C)/2$ satisfy the equations above, and $a^2+b^2+c^2-d^2 = s^2(\beta^2+\gamma^2-AC) > 0$; choosing $s > 0$ with $a^2+b^2+c^2 = 1$ gives a plane with $1-d^2 > 0$ whose circle corresponds to the given generalised circle. □

Stereographic projection also preserves angles between curves; equivalently, the round metric of S^2 pulls back to the conformal metric $4|dz|^2/(1+|z|^2)^2$ (Chapter 40).

29.7.2 Meromorphic functions on the sphere

The behaviour of a function at ∞ is defined through the coordinate $w = 1/z$.

Definition 29.7.4. Let f be holomorphic on $\{|z| > R\}$, and $g(w) = f(1/w)$ on $0 < |w| < 1/R$. Then f is *holomorphic at* ∞, has a *pole*, a *zero* or an *essential singularity* at ∞, if g has the corresponding property at 0, and $\operatorname{ord}_\infty f = \operatorname{ord}_0 g$. In terms of the Laurent expansion $f(z) = \sum_{n\in\mathbb{Z}} c_n z^n$ on $|z| > R$ (Theorem 29.5.1), where $g(w) = \sum_n c_n w^{-n}$: f is holomorphic at ∞ if $c_n = 0$ for $n > 0$, and has a pole of order m if $c_m \neq 0$ and $c_n = 0$ for $n > m$. The *residue at* ∞ is

$$\operatorname{Res}_\infty f = -\frac{1}{2\pi i}\int_{|z|=\rho} f(z)\,dz = -c_{-1} \qquad (\rho > R),$$

the circle traversed counterclockwise. A function f on $\hat{\mathbb{C}}$ is *meromorphic* if it is meromorphic on $\mathbb{C}$ and holomorphic or has a pole at ∞; it is regarded as a map $\hat{\mathbb{C}} \to \hat{\mathbb{C}}$ by sending the poles to ∞, which is continuous by Proposition 29.5.3(2).

The residue at ∞ is not the residue of g at 0: it belongs to the differential $f(z)\,dz = -f(1/w)w^{-2}\,dw$, and $\operatorname{Res}_\infty f = \operatorname{Res}_0(-g(w)/w^2)$. For instance $f(z) = 1/z$ is holomorphic at ∞, with a zero of order 1 there, but $\operatorname{Res}_\infty(1/z) = -1$. The minus sign is there because the circle $|z| = \rho$, traversed counterclockwise, goes around ∞ clockwise.

A rational function $R = p/q$, with p, q coprime polynomials and $q \neq 0$, is meromorphic on $\hat{\mathbb{C}}$: near ∞, $R(z) = z^{\deg p - \deg q} h(1/z)$ with h holomorphic near 0 and $h(0) \neq 0$ (the ratio of the leading coefficients), so

$$\operatorname{ord}_\infty \frac{p}{q} = \deg q - \deg p. \tag{29.2}$$

The *degree* of R is $\deg R = \max(\deg p, \deg q)$.

Theorem 29.7.5. *The meromorphic functions on $\hat{\mathbb{C}}$ are exactly the rational functions. More precisely, if f is meromorphic on $\hat{\mathbb{C}}$, with poles $a_1, \dots, a_k$ in $\mathbb{C}$, principal parts $P_j(z) = \sum_{n=1}^{m_j} c_{-n}^{(j)}(z - a_j)^{-n}$ there, and principal part $P_\infty(z) = \sum_{n=1}^{m} c_n z^n$ at ∞ (the positive part of its Laurent expansion at ∞), then*

$$f = c + P_\infty + P_1 + \cdots + P_k$$

for a constant c. This is the partial fraction decomposition *of f, and it is unique.*

Proof. Let $f = \sum_n c_n z^n$ on $|z| > R$. Since f is not essential at ∞, $c_n = 0$ for large n, so P_∞ is a polynomial. The poles of f in $\mathbb{C}$ lie in the compact disc $|z| \leq R$, where f is holomorphic outside a discrete closed set of poles, so there are finitely many, $a_1, \dots, a_k$. Each P_j is a rational function, holomorphic on $\hat{\mathbb{C}} \setminus \{a_j\}$ and vanishing at ∞. The function $h = f - P_\infty - \sum_j P_j$ has removable singularities at the a_j, so it extends to an entire function. As $z \to \infty$, $f(z) - P_\infty(z) = \sum_{n \leq 0} c_n z^n \to c_0$ and $P_j(z) \to 0$, so h is bounded outside a large disc, hence bounded on $\mathbb{C}$, and constant by Liouville's theorem (Corollary 29.4.7). So f is rational. Uniqueness: the principal parts, and hence c, are determined by f. □

So a meromorphic function on $\hat{\mathbb{C}}$ is determined, up to an additive constant, by its principal parts, and up to a multiplicative constant by its zeros and poles: if f and g have the same zeros and poles with the same orders, f/g is meromorphic on $\hat{\mathbb{C}}$ with only removable singularities, so it has no principal parts and is constant by the theorem. This is the simplest instance of the interplay of local data and global holomorphic functions studied for general compact Riemann surfaces in Chapter 59.

Proposition 29.7.6. *Let R be a nonconstant rational function of degree d. For every $w \in \hat{\mathbb{C}}$, the equation $R(z) = w$ has exactly d solutions in $\hat{\mathbb{C}}$, counted with multiplicity; here the multiplicity of a solution a is $\operatorname{ord}_a(R - w)$ if a and w are finite, and is defined through the coordinates $1/z$ near $z = \infty$ and $1/R$ near $w = \infty$ otherwise. Consequently $\sum_{a \in \hat{\mathbb{C}}} \operatorname{ord}_a R = 0$: a rational function has as many zeros as poles on $\hat{\mathbb{C}}$, counted with multiplicity.*

Proof. Write $R = p/q$ with p, q coprime. Let $w \in \mathbb{C}$. The finite solutions of $R(z) = w$ are the roots of $p - wq$: at a root a of $p - wq$ we have $q(a) \neq 0$, as otherwise $p(a) = 0$ too, and then $\operatorname{ord}_a(R - w) = \operatorname{ord}_a(p - wq)$. By the fundamental theorem of algebra, these multiplicities add up to $e = \deg(p - wq) \leq d$. The point ∞ is a solution exactly when $R - w = (p - wq)/q$ vanishes at ∞, with multiplicity $\deg q - e$ by (29.2). If $\deg p > \deg q$, then $e = \deg p = d$ and $R(\infty) = \infty \neq w$. If $\deg p \leq \deg q = d$, then either $e = d$, and $R - w$ does not vanish at ∞; or $e < d$, and ∞ is a solution of multiplicity $d - e$. In all cases the total is d. For $w = \infty$, the solutions are the poles: the roots of q, with multiplicities adding up to $\deg q$, and ∞ if $\deg p > \deg q$, with multiplicity $\deg p - \deg q$; the total is again d. Finally $\sum_a \operatorname{ord}_a R$ is the number of zeros minus the number of poles, $d - d = 0$. □

Proposition 29.7.7. *For every rational function R, $\sum_{a\in\hat{\mathbb{C}}} \operatorname{Res}_a R = 0$, the sum running over ∞ and the poles of R in $\mathbb{C}$.*

Proof. Choose ρ larger than the absolute values of all poles of R in $\mathbb{C}$. By the residue theorem in the simply connected set $\mathbb{C}$ (Theorem 29.5.8), $\frac{1}{2\pi i}\int_{|z|=\rho} R(z)\,dz = \sum_{a\in\mathbb{C}} \operatorname{Res}_a R$, and the left side is $-\operatorname{Res}_\infty R$ by definition. □

Example 29.7.8.

1. The residue at ∞ often computes a contour integral at once. For $n \geq 2$, $\int_{|z|=2} \frac{dz}{z^n-1} = 0$, because $\frac{1}{z^n-1} = z^{-n}(1+z^{-n}+z^{-2n}+\cdots)$ for $|z|>1$ has $c_{-1}=0$; computing the n residues at the roots of unity would be longer. Similarly $\int_{|z|=2} \frac{z^{n-1}\,dz}{z^n-1} = 2\pi i$, which is also $2\pi i$ times the number of roots of z^n-1 in the disc, by the argument principle (Theorem 29.5.10).

2. Applying the proposition to $R(z) = \frac{1}{z(z-1)}$: the residues at 0 and 1 are -1 and 1, and indeed $R = z^{-2}(1+z^{-1}+\cdots)$ has $\operatorname{Res}_\infty R = 0$.

3. A polynomial of degree $d \geq 1$ is a rational function of degree d with a single pole, of order d, at ∞; Proposition 29.7.6 says it takes every value d times in $\mathbb{C}$, which is the fundamental theorem of algebra.

29.7.3 Möbius transformations

Definition 29.7.9. For $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{C})$, the *Möbius transformation* $M_A\colon \hat{\mathbb{C}} \to \hat{\mathbb{C}}$ is

$$M_A(z) = \frac{az+b}{cz+d},$$

with $M_A(-d/c) = \infty$ and $M_A(\infty) = a/c$ if $c \neq 0$, and $M_A(\infty) = \infty$ if $c = 0$.

It is convenient to write points of $\hat{\mathbb{C}}$ in *homogeneous coordinates*: the nonzero vector $(z_1, z_2) \in \mathbb{C}^2$ represents $z_1/z_2 \in \hat{\mathbb{C}}$ (with $z_1/0 = \infty$), and two vectors represent the same point if and only if they are proportional. So $\hat{\mathbb{C}}$ is the set of lines through 0 in $\mathbb{C}^2$, the *complex projective line* $\mathbb{P}^1(\mathbb{C})$, and M_A is the map induced by the linear map A: if (z_1, z_2) represents z, then $A(z_1, z_2) = (az_1 + bz_2, cz_1 + dz_2)$ represents $M_A(z)$. (The cases with ∞ in the definition are exactly what this description gives.)

Proposition 29.7.10.

1. *$M_A M_B = M_{AB}$, and $M_A = \mathrm{id}$ if and only if A is a scalar matrix. So the Möbius transformations form a group, isomorphic to $\mathrm{PGL}_2(\mathbb{C}) = \mathrm{GL}_2(\mathbb{C})/\mathbb{C}^*$, and also to $\mathrm{PSL}_2(\mathbb{C}) = \mathrm{SL}_2(\mathbb{C})/\{\pm 1\}$.*

2. *Each M_A is a homeomorphism of $\hat{\mathbb{C}}$ and a rational function of degree 1; its derivative $\det A/(cz+d)^2$ never vanishes on $\mathbb{C}\setminus\{-d/c\}$. Conversely every rational function of degree 1, and every bijective meromorphic function $\hat{\mathbb{C}} \to \hat{\mathbb{C}}$, is a Möbius transformation.*

3. *The Möbius transformations are generated by the translations $z \mapsto z+b$, the maps $z \mapsto az$ ($a \neq 0$) and the inversion $z \mapsto 1/z$.*

4. *Möbius transformations map generalised circles to generalised circles.*

Proof. (1) The first statement is the description in homogeneous coordinates: AB induces the composite of the maps induced by B and A. If $M_A = \mathrm{id}$, every line in $\mathbb{C}^2$ is mapped to itself, so every nonzero vector is an eigenvector of A; then e_1, e_2 and $e_1 + e_2$ are eigenvectors, which forces the two eigenvalues for e_1, e_2 to agree, and A is scalar. So $A \mapsto M_A$ induces an isomorphism from $\mathrm{GL}_2(\mathbb{C})/\mathbb{C}^*$ onto the group of Möbius transformations. Every A is a scalar

multiple of a matrix of determinant 1 (divide by a square root of $\det A$), and a scalar matrix of determinant 1 is ± 1, which gives the second description.

(2) M_A is bijective with inverse $M_{A^{-1}}$. It is continuous on $\hat{\mathbb{C}}$: away from $-d/c$ and ∞ this is clear, $|M_A(z)| \to \infty$ as $z \to -d/c$ since the numerator does not vanish there ($a(-d/c)+b = -\det A/c$), and $M_A(z) \to a/c$ (or ∞ if $c = 0$) as $z \to \infty$. A continuous bijection of the compact Hausdorff space $\hat{\mathbb{C}}$ is a homeomorphism. The polynomials $az + b$ and $cz + d$ are coprime, since $ad - bc \neq 0$, so M_A has degree 1, and the formula for the derivative is the quotient rule. Conversely, a rational function $(az + b)/(cz + d)$ of degree 1 in lowest terms has $ad - bc \neq 0$, since otherwise the numerator and denominator would be proportional. If f is a meromorphic bijection of $\hat{\mathbb{C}}$, it is rational (Theorem 29.7.5) of some degree $d \geq 1$, and by Proposition 29.7.6 each value has a single preimage, of multiplicity d. If $d \geq 2$, then f' would vanish at every point of $\mathbb{C}$ that is not a pole and not mapped to ∞, which is impossible for a nonconstant function. So $d = 1$.

(3) If $c = 0$, $M_A(z) = (a/d)z + b/d$. If $c \neq 0$, $M_A(z) = \frac{a}{c} - \frac{\det A}{c(cz+d)}$, the composite of $z \mapsto cz + d$, $z \mapsto 1/z$, multiplication by $-\det A/c$ and translation by a/c.

(4) By (3) it suffices to check the generators. Translations and the maps $z \mapsto az$ are similarities of the plane, which map circles to circles and lines to lines, and fix ∞. The inversion corresponds under τ to a rotation of S^2 (Proposition 29.7.2(2)), which maps plane sections of S^2 to plane sections; by Proposition 29.7.3 it maps generalised circles to generalised circles. □

The proof of (4) by the sphere avoids a computation; directly, substituting $z = 1/u$ in (29.1) and multiplying by $|u|^2$ gives $A + 2\beta \operatorname{Re} u - 2\gamma \operatorname{Im} u + C|u|^2 = 0$, again of the same form. Under inversion, circles through 0 become lines, and lines not through 0 become circles through 0.

Theorem 29.7.11. *Given distinct points $z_1, z_2, z_3 \in \hat{\mathbb{C}}$ and distinct points $w_1, w_2, w_3 \in \hat{\mathbb{C}}$, there is exactly one Möbius transformation M with $M(z_i) = w_i$ for $i = 1, 2, 3$.*

Proof. If $z_1, z_2, z_3 \in \mathbb{C}$, the map

$$S(z) = \frac{(z - z_1)(z_2 - z_3)}{(z - z_3)(z_2 - z_1)}$$

is Möbius, with $S(z_1) = 0$, $S(z_2) = 1$, $S(z_3) = \infty$. If one of the z_i is ∞, delete the two factors containing it: $S(z) = \frac{z_2 - z_3}{z - z_3}$, $\frac{z - z_1}{z - z_3}$ or $\frac{z - z_1}{z_2 - z_1}$ for z_1, z_2 or $z_3 = \infty$. Doing the same for the w_i gives T, and $M = T^{-1}S$ has the required property. For uniqueness it suffices to show that a Möbius map fixing 0, 1, ∞ is the identity: from $M(\infty) = \infty$, $c = 0$, so $M(z) = \alpha z + \beta$; then $M(0) = 0$ gives $\beta = 0$ and $M(1) = 1$ gives $\alpha = 1$. □

Definition 29.7.12. For distinct $z_1, z_2, z_3 \in \hat{\mathbb{C}}$ and $z \in \hat{\mathbb{C}}$, the *cross-ratio* (z, z_1, z_2, z_3) is $S(z)$, for the unique Möbius S with $S(z_1) = 0$, $S(z_2) = 1$, $S(z_3) = \infty$; for finite points

$$(z, z_1, z_2, z_3) = \frac{(z - z_1)(z_2 - z_3)}{(z - z_3)(z_2 - z_1)}.$$

Corollary 29.7.13. *1. For every Möbius transformation M, $(Mz, Mz_1, Mz_2, Mz_3) = (z, z_1, z_2, z_3)$.*

2. Four distinct points z, z_1, z_2, z_3 lie on a generalised circle if and only if (z, z_1, z_2, z_3) is real.

Proof. (1) SM^{-1} sends Mz_1, Mz_2, Mz_3 to 0, 1, ∞, so it is the map defining the left side, and its value at Mz is $S(z)$. (2) Let C be the generalised circle through z_1, z_2, z_3. By Proposition 29.7.10(4), applied to S and S^{-1}, S maps C onto the generalised circle through 0, 1, ∞, which is $\mathbb{R} \cup \{\infty\}$. So $z \in C$ if and only if $S(z) \in \mathbb{R} \cup \{\infty\}$, and $S(z) \neq \infty$ since $z \neq z_3$. □

29.7.4 Fixed points and conjugacy classes

A point $z = z_1/z_2$ is fixed by M_A if and only if (z_1, z_2) is an eigenvector of A. Since A has one or two eigenlines unless it is scalar, a Möbius transformation other than the identity has one or two fixed points in $\hat{\mathbb{C}}$. Normalising $\det A = 1$, the trace $\operatorname{tr} A$ is determined by M_A up to sign, so $(\operatorname{tr} A)^2$ is an invariant of M_A, unchanged under conjugation $M \mapsto NMN^{-1}$.

Theorem 29.7.14. *Let $M = M_A \neq \mathrm{id}$ with $\det A = 1$, and $t = \operatorname{tr} A$.*

1. *If $t^2 = 4$, M has exactly one fixed point and is conjugate to the translation $z \mapsto z + 1$; M is called* parabolic.
2. *If $t^2 \neq 4$, M has exactly two fixed points and is conjugate to $z \mapsto kz$ for some $k \neq 0, 1$, determined up to $k \leftrightarrow k^{-1}$ by $k + 2 + k^{-1} = t^2$. Then M is called* elliptic *if $|k| = 1$, equivalently $t \in (-2, 2)$;* hyperbolic *if $k > 0$, equivalently $t \in \mathbb{R}$ with $|t| > 2$; and* loxodromic *otherwise, equivalently $t \notin \mathbb{R}$.*

Two Möbius transformations other than the identity are conjugate if and only if they have the same invariant t^2.

Proof. Conjugating M_A by M_P replaces A by PAP^{-1}. By the Jordan normal form (Theorem 11.8.4), a non-scalar $A \in \mathrm{SL}_2(\mathbb{C})$ is conjugate either to $\left(\begin{smallmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{smallmatrix}\right)$ with $\lambda \neq \lambda^{-1}$, or to $\left(\begin{smallmatrix} \lambda & 1 \\ 0 & \lambda \end{smallmatrix}\right)$ with $\lambda^2 = 1$; a diagonal matrix with $\lambda = \lambda^{-1}$ would be scalar. In the second case $t = 2\lambda = \pm 2$, M is conjugate to $z \mapsto z \pm 1$, and $z \mapsto z - 1$ is conjugate to $z \mapsto z + 1$ by $z \mapsto -z$; the only fixed point of a translation is ∞. In the first case M is conjugate to $z \mapsto kz$ with $k = \lambda^2 \neq 1$, which fixes 0 and ∞, and $t^2 = (\lambda + \lambda^{-1})^2 = k + 2 + k^{-1}$; here $t^2 \neq 4$ since $k \neq 1$. Exchanging the eigenvectors replaces k by k^{-1}. The eigenvalues λ, λ^{-1} are the roots of $X^2 - tX + 1$, and $k = \lambda^2$. If $t \in (-2, 2)$, the roots are non-real and conjugate with product 1, so $|\lambda| = 1$ and $|k| = 1$; conversely $|\lambda| = 1$ gives $t = \lambda + \bar{\lambda} = 2 \operatorname{Re} \lambda \in [-2, 2]$, and $t \neq \pm 2$ as $t^2 \neq 4$. If t is real with $|t| > 2$, the roots are real, so $k > 0$; conversely $k > 0$ means $\lambda \in \mathbb{R}$, so $t = \lambda + \lambda^{-1}$ is real, and $|t| > 2$ since $\lambda \neq \pm 1$. As $t^2 \neq 4$, a real t falls in one of these two cases, so the remaining, loxodromic, case is $t \notin \mathbb{R}$. Finally, transformations with the same t^2 are conjugate, since both are conjugate to the same normal form ($z \mapsto z + 1$, or $z \mapsto kz$ with k determined up to inversion, and $z \mapsto k^{-1}z$ is conjugate to $z \mapsto kz$ by $z \mapsto 1/z$). □

The names describe the dynamics. A hyperbolic map $z \mapsto kz$, $k > 1$, pushes every point away from the repelling fixed point 0 towards the attracting fixed point ∞ along rays; an elliptic map $z \mapsto e^{i\theta}z$ rotates around its two fixed points, and corresponds to a rotation of the sphere about the axis through them; a loxodromic map spirals from one fixed point to the other; and a parabolic map moves points along circles tangent at the single fixed point. For example $z \mapsto 1/z$, with matrix $i\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ of determinant 1 and trace 0, is elliptic of order 2 with fixed points ± 1, in accordance with Proposition 29.7.2(2).

29.7.5 The disc, the half-plane and the sphere

Three subgroups of the Möbius group correspond to the three simply connected Riemann surfaces of the uniformisation theorem (Chapter 44): the sphere, the plane and the disc.

Proposition 29.7.15. *Let $\mathbb{H} = \{\operatorname{Im} z > 0\}$.*

1. *The* Cayley transform $\kappa(z) = \frac{z-i}{z+i}$ *maps $\mathbb{H}$ biholomorphically onto $\mathbb{D}$, and $\mathbb{R} \cup \{\infty\}$ onto the unit circle.*
2. *For $A \in \mathrm{SL}_2(\mathbb{R})$, $\operatorname{Im} M_A(z) = \operatorname{Im} z/|cz + d|^2$, so M_A maps $\mathbb{H}$ onto itself.*

3. *Every biholomorphic self-map of $\mathbb{H}$ is M_A for some $A \in \mathrm{SL}_2(\mathbb{R})$, unique up to sign; so* $\mathrm{Aut}(\mathbb{H}) \cong \mathrm{PSL}_2(\mathbb{R})$.

Proof. (1) $|\kappa(z)| < 1$ if and only if $|z - i| < |z + i|$, that is, z is closer to i than to $-i$, that is, $\operatorname{Im} z > 0$; similarly $|\kappa(z)| = 1$ exactly on $\mathbb{R}$, and $\kappa(\infty) = 1$. Since κ is a bijection of $\hat{\mathbb{C}}$, it maps $\mathbb{H}$ onto $\mathbb{D}$, and it is holomorphic with holomorphic inverse $M_{A^{-1}}$.

(2) $(az + b)(c\bar{z} + d) = ac|z|^2 + adz + bc\bar{z} + bd$ has imaginary part $(ad - bc)\operatorname{Im} z = \operatorname{Im} z$, and $\operatorname{Im} M_A(z) = \operatorname{Im}\big((az + b)(c\bar{z} + d)\big)/|cz + d|^2$. So M_A maps $\mathbb{H}$ into itself, and so does its inverse $M_{A^{-1}}$, $A^{-1} \in \mathrm{SL}_2(\mathbb{R})$.

(3) Let f be a biholomorphic self-map of $\mathbb{H}$. Then $\kappa f \kappa^{-1}$ is a biholomorphic self-map of $\mathbb{D}$, hence a Möbius transformation by Proposition 29.6.2, and so $f = M$ is Möbius. As a homeomorphism of $\hat{\mathbb{C}}$ mapping $\mathbb{H}$ onto itself, M maps the boundary $\mathbb{R} \cup \{\infty\}$ of $\mathbb{H}$ onto itself. Choose three distinct real points z_i; the $w_i = M(z_i)$ lie in $\mathbb{R} \cup \{\infty\}$, and in the proof of Theorem 29.7.11 the maps S and T have real coefficients, so $M = T^{-1}S = M_A$ with $A \in \mathrm{GL}_2(\mathbb{R})$. By the computation in (2), $\operatorname{Im} M_A(z) = \det A \operatorname{Im} z/|cz + d|^2$, so $\det A > 0$, and dividing A by $\sqrt{\det A}$ gives $A \in \mathrm{SL}_2(\mathbb{R})$. Finally $M_A = M_B$ with $A, B \in \mathrm{SL}_2(\mathbb{R})$ forces $A = \pm B$ by Proposition 29.7.10(1). □

So the three groups are: all of $\mathrm{PSL}_2(\mathbb{C})$ for the sphere (Proposition 29.7.10(2)); the affine maps $z \mapsto az + b$, the Möbius maps fixing ∞, for the plane (Exercise 29.8.2); and $\mathrm{PSL}_2(\mathbb{R}) \cong \mathrm{PSU}(1,1)$ for the half-plane or the disc. The subgroup $\mathrm{PSL}_2(\mathbb{Z})$ acting on $\mathbb{H}$ gives the moduli space of elliptic curves (Chapter 51).

The rotations of the sphere form a fourth, compact, subgroup. In homogeneous coordinates the chordal distance of Proposition 29.7.2 reads

$$\|\tau(z) - \tau(w)\| = \frac{2|z_1 w_2 - z_2 w_1|}{\|(z_1, z_2)\|\,\|(w_1, w_2)\|} \qquad (z = z_1/z_2,\ w = w_1/w_2),$$

as one sees by taking $z_2 = w_2 = 1$ (both sides are unchanged by rescaling either vector, and the case of ∞ follows by continuity). The numerator is $|\det|$ of the matrix with columns (z_1, z_2) and (w_1, w_2), so a matrix $A \in \mathrm{SU}(2)$, which preserves determinants and norms, gives a Möbius transformation M_A preserving the chordal distance, an isometry of S^2. These isometries are rotations, and every rotation arises in this way; this is the double covering $\mathrm{SU}(2) \to \mathrm{SO}(3)$ of Chapter 34. The matrices in $\mathrm{SU}(2)$ are those of the form $\left(\begin{smallmatrix} a & -\bar{b} \\ b & \bar{a} \end{smallmatrix}\right)$ with $|a|^2 + |b|^2 = 1$; for instance $z \mapsto e^{i\theta} z$ is the rotation by θ about the vertical axis.

Remark 29.7.16.

1. *Riemann surfaces.* With the two charts z and $1/z$, $\hat{\mathbb{C}}$ is a compact Riemann surface, biholomorphic to the projective line $\mathbb{CP}^1$; meromorphic functions on $\hat{\mathbb{C}}$ are the holomorphic maps $\hat{\mathbb{C}} \to \hat{\mathbb{C}}$ other than the constant ∞, and the Möbius transformations are its automorphisms (Chapter 44). It is the only compact Riemann surface of genus 0.

2. *Riemann–Hurwitz.* A rational function of degree d has $2d - 2$ critical points on $\hat{\mathbb{C}}$, counted with multiplicity; for a polynomial of degree d these are the $d - 1$ zeros of p' and the point ∞, of multiplicity $d - 1$. This is the Riemann–Hurwitz formula for maps $\hat{\mathbb{C}} \to \hat{\mathbb{C}}$ [For81].

3. *Iteration.* Iterating a rational function of degree $d \geq 2$ on $\hat{\mathbb{C}}$ is the subject of complex dynamics, with its Julia and Fatou sets; the family $z \mapsto z^2 + c$ gives the Mandelbrot set. For Möbius transformations iteration is simple, by Theorem 29.7.14: the iterates of $z \mapsto kz$ are $z \mapsto k^n z$, and those of $z \mapsto z + 1$ are $z \mapsto z + n$.

29.8 Exercises

Exercise 29.8.1. Show that $\mathbb{D}$ and $\mathbb{C}$ are not biholomorphic, although they are homeomorphic.

Solution. A biholomorphism $\mathbb{C} \to \mathbb{D}$ would be a bounded entire function, hence constant (Corollary 29.4.7). They are homeomorphic by $z \mapsto z/(1+|z|)$ (Counterexample 18.7.10). □

Exercise 29.8.2. Show that every biholomorphic map $\mathbb{C} \to \mathbb{C}$ is $z \mapsto az + b$ with $a \neq 0$.

Solution. Let f be such a map and consider $g(z) = f(1/z)$ on $\mathbb{C}^\times$. If 0 were an essential singularity of g, then by Casorati–Weierstrass the image $f(\{|z| > 1\})$ would be dense, while $f(\mathbb{D})$ is open and disjoint from it, a contradiction. So g has a pole or removable singularity at 0, which means $|f(z)| \leq C|z|^m$ for large $|z|$; by Liouville's theorem f is a polynomial, and it is injective only if $\deg f = 1$. □

Exercise 29.8.3. Use Rouché's theorem to show that $z^5 + 3z + 1$ has exactly one root in $\mathbb{D}$ and all five roots in $D(0,2)$.

Exercise 29.8.4. Compute $\int_0^{2\pi} \frac{dt}{a+\cos t}$ for $a > 1$ by writing $z = e^{it}$ and using the residue theorem.

Exercise 29.8.5. Give an example of a domain U and a nowhere vanishing holomorphic f on U with no holomorphic logarithm, and relate this to $\pi_1(U)$.

Exercise 29.8.6. Find the Möbius transformation sending $1, i, -1$ to $0, 1, \infty$, and show that it maps $\mathbb{D}$ onto $\mathbb{H}$. Find a Möbius transformation mapping the half-plane $\{\operatorname{Re} z > 0\}$ onto $\mathbb{D}$ with $1 \mapsto 0$.

Solution. By Theorem 29.7.11, $S(z) = \frac{(z-1)(i+1)}{(z+1)(i-1)}$, and $\frac{1+i}{i-1} = -i$, so $S(z) = i\frac{1-z}{1+z}$. It maps the unit circle, through $1, i, -1$, onto $\mathbb{R} \cup \{\infty\}$, so it maps $\mathbb{D}$ onto one of the two half-planes; as $S(0) = i$, it is $\mathbb{H}$. For the second part, $z \mapsto iz$ maps $\{\operatorname{Re} z > 0\}$ onto $\mathbb{H}$, and then the Cayley transform gives $\frac{iz-i}{iz+i} = \frac{z-1}{z+1}$, which sends 1 to 0. □

Exercise 29.8.7. Let $\lambda = (z, z_1, z_2, z_3)$. Show that permuting the four points changes the cross-ratio into one of λ, $1-\lambda$, $1/\lambda$, $1/(1-\lambda)$, $(\lambda-1)/\lambda$, $\lambda/(\lambda-1)$, and that each value is obtained from four of the 24 permutations.

Solution. We may assume the four points are finite (move them by a Möbius map, Corollary 29.7.13(1)). The permutations $(z\, z_1)(z_2\, z_3)$, $(z\, z_2)(z_1\, z_3)$ and $(z\, z_3)(z_1\, z_2)$ leave the cross-ratio unchanged: for instance $(z_1, z, z_3, z_2) = \frac{(z_1-z)(z_3-z_2)}{(z_1-z_2)(z_3-z)}$, and numerator and denominator are those of (z, z_1, z_2, z_3), each with two signs changed; the other two are similar. With the identity they form a normal subgroup V of order 4, and every permutation is the product of an element of V and a permutation fixing the first entry, so it suffices to permute z_1, z_2, z_3. Moving them to $0, 1, \infty$, so that $z = \lambda$, and using the formulas of Theorem 29.7.11 for points at ∞:

$$(\lambda,0,1,\infty) = \lambda, \quad (\lambda,1,0,\infty) = 1-\lambda, \quad (\lambda,0,\infty,1) = \frac{\lambda}{\lambda-1}, \quad (\lambda,1,\infty,0) = \frac{\lambda-1}{\lambda}, \quad (\lambda,\infty,0,1) = \frac{1}{1-\lambda}, \quad (\lambda,$$

Each value is obtained from a coset of V, that is, from four permutations. □

Exercise 29.8.8. Classify the following Möbius transformations as parabolic, elliptic, hyperbolic or loxodromic, and find their fixed points: $z \mapsto \frac{z}{z+1}$, $z \mapsto \frac{2z+1}{z+1}$, $z \mapsto 2iz$, $z \mapsto -\frac{1}{z}$, $z \mapsto \frac{z-i}{z+i}$. Show that a Möbius transformation of finite order $n \geq 2$ is elliptic and conjugate to $z \mapsto e^{2\pi ij/n}z$ for some j prime to n.

Solution. Compute $t^2 = (\operatorname{tr} A)^2/\det A$, which is the invariant for the normalised matrix. $\frac{z}{z+1}$: $t^2 = 4$, parabolic, fixed point 0. $\frac{2z+1}{z+1}$: $t^2 = 9$, hyperbolic, fixed points $z^2 - z - 1 = 0$, $z = (1 \pm \sqrt{5})/2$. $2iz$: $t^2 = (1+2i)^2/(2i) = (-3+4i)/(2i) = 2 + \frac{3}{2}i$, loxodromic, fixed points 0, ∞. $-1/z$: $t^2 = 0$, elliptic, fixed points $\pm i$. $\frac{z-i}{z+i}$: $t^2 = 4/(2i) = -2i$, loxodromic, fixed points the roots of $z^2 + (i-1)z + i = 0$. If $M^n = \mathrm{id}$ with $M \neq \mathrm{id}$, then M is not parabolic (the iterates of $z+1$ are $z+n$), so it is conjugate to $z \mapsto kz$ with $k^n = 1$, $k \neq 1$, which is elliptic; replacing n by the exact order, k is a primitive n-th root of unity. □

Exercise 29.8.9. Let $J(z) = \frac{1}{2}(z + z^{-1})$. Show that J is a rational function of degree 2 with critical points ± 1, that it maps the circle $|z| = r \neq 1$ onto an ellipse with foci ± 1 and the unit circle onto $[-1, 1]$, and that it maps $\mathbb{D} \setminus \{0\}$ biholomorphically onto $\mathbb{C} \setminus [-1, 1]$. (This *Joukowski map* was used to model the flow around aircraft wings.)

Solution. $J = (z^2+1)/(2z)$ has degree 2, and $J'(z) = \frac{1}{2}(1 - z^{-2})$ vanishes at ± 1. For $z = re^{i\theta}$, $J(z) = \frac{1}{2}(r+r^{-1})\cos\theta + \frac{i}{2}(r-r^{-1})\sin\theta$, an ellipse with semi-axes $a = \frac{1}{2}(r+r^{-1})$ and $b = \frac{1}{2}|r-r^{-1}|$, so $a^2 - b^2 = 1$ and the foci are ± 1; for $r = 1$ it is $\cos\theta \in [-1, 1]$. Next $J(z) = J(w)$ if and only if $(z-w)(1 - \frac{1}{zw}) = 0$, that is, $w = z$ or $w = 1/z$; so J is injective on $\mathbb{D} \setminus \{0\}$. Every $w \in \mathbb{C}$ is taken twice counted with multiplicity (Proposition 29.7.6), by z and $1/z$; if $w \notin [-1, 1]$, neither lies on the unit circle, so exactly one lies in $\mathbb{D} \setminus \{0\}$. The inverse is holomorphic, since $J' \neq 0$ on $\mathbb{D} \setminus \{0\}$. □

Exercise 29.8.10. Let $a \neq b$ in $\mathbb{C}$ and $k > 0$. Show that $\{z : |z-a| = k|z-b|\}$ is a circle for $k \neq 1$ and the perpendicular bisector of a and b for $k = 1$ (a *circle of Apollonius*). Deduce that the images of the circles $|w| = k$ under the Möbius map $w \mapsto \frac{a-bw}{1-w}$, inverse of $z \mapsto \frac{z-a}{z-b}$, are these circles.

Solution. Squaring, $|z|^2 - 2\operatorname{Re}(z\bar{a}) + |a|^2 = k^2(|z|^2 - 2\operatorname{Re}(z\bar{b}) + |b|^2)$, that is, $(1-k^2)|z|^2 - 2\operatorname{Re}\big(z(\bar{a} - k^2\bar{b})\big) + |a|^2 - k^2|b|^2 = 0$, which is of the form (29.1); it is a line, the bisector, if $k = 1$. For $k \neq 1$ the set is nonempty and not a point (it meets the line through a and b in two points, dividing the segment internally and externally in the ratio k), so it is a circle. The second statement is the first, since $|w| = k$ means $|z-a| = k|z-b|$ for z the preimage of w. □

Exercise 29.8.11. Compute $\int_{|z|=3} \frac{z^5\,dz}{(z-1)(z^5+2)}$ using the residue at ∞.

Solution. All poles lie in $|z| < 3$. For large $|z|$, $\frac{z^5}{(z-1)(z^5+2)} = \frac{1}{z-1} \cdot \frac{1}{1+2z^{-5}} = z^{-1}(1 + z^{-1} + \cdots)(1 - 2z^{-5} + \cdots)$, whose coefficient of z^{-1} is 1. So $\operatorname{Res}_\infty = -1$ and, by Proposition 29.7.7, the integral is $2\pi i \sum_{a\in\mathbb{C}} \operatorname{Res}_a = -2\pi i \operatorname{Res}_\infty = 2\pi i$. □

Exercise 29.8.12. Let $f = u + iv$ be holomorphic on a connected open set U. Show that f is constant if any of the following holds: (1) u is constant; (2) f takes only real values; (3) $|f|$ is constant; (4) $\bar{f}$ is also holomorphic.

Solution. If $f' = 0$ on U, then f is constant on every disc in U (Lemma 29.2.8, integrating along segments), so the set where f takes a given value is open, as is its complement, and f is constant since U is connected. (1) If u is constant, $\partial_x u = \partial_y u = 0$, so $\partial_x v = -\partial_y u = 0$ by the Cauchy–Riemann equations, and $f' = \partial_x u + i\partial_x v = 0$. (2) Then $v = 0$, and $-if = v - iu$ has constant real part; apply (1). (3) If $|f|^2$ is constant, then $0 = \Delta|f|^2 = 4|f'|^2$ by Example 29.4.5(3). (4) Then $f + \bar{f} = 2u$ is holomorphic and real valued; by (2) u is constant, and (1) applies. □

Exercise 29.8.13. (*Cauchy–Riemann equations in polar coordinates.*) Let $f = u + iv$ be real differentiable on an open set $U \subseteq \mathbb{C}^\times$, and write $z = re^{i\theta}$. Show that f is holomorphic if and only if

$$\partial_r u = \frac{1}{r}\partial_\theta v, \qquad \partial_r v = -\frac{1}{r}\partial_\theta u,$$

and that then $f'(z) = e^{-i\theta}\partial_r f$. Deduce that the principal logarithm $\operatorname{Log} z = \log r + i\theta$, $-\pi < \theta < \pi$, is holomorphic on $\mathbb{C} \setminus (-\infty, 0]$ with derivative $1/z$.

Solution. By the chain rule, $\partial_r = \cos\theta\,\partial_x + \sin\theta\,\partial_y$ and $\partial_\theta = -r\sin\theta\,\partial_x + r\cos\theta\,\partial_y$ on functions of $(x, y) = (r\cos\theta, r\sin\theta)$. Hence

$$\partial_\theta f - ir\,\partial_r f = r\big((-\sin\theta - i\cos\theta)\partial_x f + (\cos\theta - i\sin\theta)\partial_y f\big) = -ire^{-i\theta}\big(\partial_x f + i\,\partial_y f\big).$$

The Cauchy–Riemann equations say $\partial_x f + i\,\partial_y f = 0$ (its real and imaginary parts are $\partial_x u - \partial_y v$ and $\partial_x v + \partial_y u$). So f is holomorphic if and only if $\partial_\theta f = ir\,\partial_r f$, whose real and imaginary parts are the stated equations. Then $\partial_r f = \cos\theta\, f' + \sin\theta\, if' = e^{i\theta} f'$. For Log, which is real differentiable because (r, θ) are smooth functions of (x, y) on the slit plane, $u = \log r$ and $v = \theta$ give $\partial_r u = \frac{1}{r} = \frac{1}{r}\partial_\theta v$ and $\partial_r v = 0 = -\frac{1}{r}\partial_\theta u$, and $\operatorname{Log}'(z) = e^{-i\theta}/r = 1/z$. □

Exercise 29.8.14. For integers $m, n \geq 0$ compute $\int_\gamma z^n \bar{z}^m\,dz$ over the unit circle $\gamma(t) = e^{2\pi i t}$. Deduce that a polynomial $p(z, \bar{z}) = \sum c_{nm} z^n \bar{z}^m$ satisfies $\int_\gamma p\,dz = 2\pi i \sum_n c_{n,n+1}$; in particular this integral can be nonzero only if p really involves $\bar{z}$.

Solution. On the circle $\bar{z} = 1/z$, so the integrand is z^{n-m}, and by Lemma 29.2.8 the integral is $2\pi i$ if $n - m = -1$ and 0 otherwise. The formula for p follows by linearity, and if p does not involve $\bar{z}$ then $c_{n,n+1} = 0$ for all n. □

Exercise 29.8.15. Show that $1/z$ is locally integrable on $\mathbb{C}$, and that for every smooth $\varphi\colon \mathbb{C} \to \mathbb{C}$ with compact support

$$\int_{\mathbb{C}} \frac{1}{z}\,\frac{\partial\varphi}{\partial\bar{z}}\,dA = -\pi\varphi(0).$$

So $1/z$ does not satisfy the weak equation of Proposition 29.4.9 on $\mathbb{C}$, although it is holomorphic on $\mathbb{C}^\times$: the weak equation sees the pole. In the language of distributions, $\frac{\partial}{\partial\bar{z}}\frac{1}{\pi z} = \delta_0$, and $\frac{1}{\pi z}$ is a fundamental solution of $\partial/\partial\bar{z}$. (Hint: in polar coordinates $\frac{\partial}{\partial\bar{z}} = \frac{e^{i\theta}}{2}\big(\partial_r + \frac{i}{r}\partial_\theta\big)$.)

Solution. In polar coordinates $z = re^{i\theta}$ the area element is $dA = r\,dr\,d\theta$ (Corollary 28.21.3 for $n = 2$, the measure $\mathcal{H}^1$ on the unit circle being $d\theta$), so $\int_{|z|<R} |z|^{-1}\,dA = \int_0^{2\pi}\int_0^R dr\,d\theta = 2\pi R < \infty$: $1/z$ is locally integrable. By the chain rule, $\partial_r = \cos\theta\,\partial_x + \sin\theta\,\partial_y$ and $\partial_\theta = -r\sin\theta\,\partial_x + r\cos\theta\,\partial_y$, so $\partial_r + \frac{i}{r}\partial_\theta = e^{-i\theta}\partial_x + ie^{-i\theta}\partial_y = 2e^{-i\theta}\frac{\partial}{\partial\bar{z}}$, which is the hint. Hence $\frac{1}{z}\frac{\partial\varphi}{\partial\bar{z}} = \frac{1}{2r}\big(\partial_r\varphi + \frac{i}{r}\partial_\theta\varphi\big)$, and by dominated convergence (the integrand is integrable) and Fubini's theorem,

$$\int_{\mathbb{C}} \frac{1}{z}\frac{\partial\varphi}{\partial\bar{z}}\,dA = \lim_{\varepsilon\to 0}\frac{1}{2}\int_\varepsilon^\infty\int_0^{2\pi}\Big(\partial_r\varphi + \frac{i}{r}\partial_\theta\varphi\Big)d\theta\,dr.$$

The θ-integral of $\partial_\theta\varphi$ vanishes, $\varphi(re^{i\theta})$ being 2π-periodic in θ, and $\int_\varepsilon^\infty \partial_r\varphi\,dr = -\varphi(\varepsilon e^{i\theta})$ since φ has compact support. So the integral is $\lim_{\varepsilon\to 0}\big(-\frac{1}{2}\int_0^{2\pi}\varphi(\varepsilon e^{i\theta})\,d\theta\big) = -\pi\varphi(0)$, by continuity of φ. □

Chapter 30

Functional Analysis

30.1 Introduction

Hodge theory rests on an analytic theorem: on a compact Riemannian manifold every cohomology class has a unique harmonic representative. The proof solves the equation $\Delta u = f$ in a space of generalised functions and then shows that the solution is smooth. The functional analysis needed for the first step is in this chapter: Hilbert spaces and orthogonal projections, the consequences of Baire's theorem, compact operators, the spectral theorem for compact self-adjoint operators (Theorem 30.6.3) and the Fredholm alternative (Theorem 30.6.4). Around this core we develop the classical theory: the applications of Baire's theorem, among them a continuous function whose Fourier series diverges (Theorem 30.5.5); the spectrum of a bounded operator and the spectral radius formula (Theorem 30.7.3); the separation of convex sets, weak closures and the direct method of the calculus of variations (Section 30.10); and dual spaces and reflexivity, with Goldstine's and Kakutani's theorems on weak compactness and the Markov–Kakutani fixed point theorem (Section 30.11). The guiding theme is what survives from finite-dimensional linear algebra and what does not: in infinite dimensions linear maps need not be continuous, norms need not be equivalent, closed bounded sets need not be compact, injective operators need not be surjective, and bases have to be replaced by orthonormal bases, whose expansions are convergent series. We also introduce Fréchet spaces, such as the space of smooth functions, whose topology is given by countably many seminorms; they are the natural home of distributions (Chapter 32). References: [Bre11], [Rud91], [RS80].

Prerequisites. Chapter 28 (Measure and Integration), Chapter 11 (Linear Algebra) and Chapter 29 (Complex Analysis).

On the way to the Hodge conjecture. Needed: Banach and Hilbert spaces, the Hahn–Banach and Baire theorems, and compact operators with their spectral theory, which the elliptic theory uses. The later sections (Section 30.5 and Sections 30.7 to 30.11) are not used on the direct route.

All vector spaces are over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$.

30.2 Banach spaces and bounded operators

Definition 30.2.1. A linear map $T\colon X \to Y$ between normed spaces is *bounded* if $\|T\| = \sup_{\|x\|\le 1} \|Tx\| < \infty$; equivalently (as for finite dimensions, Lemma 27.10.1) T is continuous. The bounded operators form a normed space $B(X, Y)$, and $X^* = B(X, \mathbb{K})$ is the *dual space*.

Proposition 30.2.2. *1. If Y is complete, so is $B(X, Y)$; in particular X^* is always a Banach space.*

2. *$C(K, \mathbb{K})$ with the supremum norm (K compact Hausdorff), $L^p(\mu)$ for $1 \le p \le \infty$, and the sequence spaces ℓ^p are Banach spaces.*

3. *(Riesz) If the closed unit ball of a normed space X is compact, then X is finite-dimensional.*
